lsclustercandidate (Discontinued)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

lscluster (Discontinued)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

lsclusterip (Discontinued)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

lsclusterstats (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsiscsiportauth

Use the **lsiscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsiscsistorageport

Use the **lsiscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsiscsistorageportcandidate

Use the **lsiscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrpghost

Use the **lsiogrpghost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode**/ **lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister.

Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lstimezone

Use the **lstimezone** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

stopcluster (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

stopsystem

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

swapnode

Use the **swaponode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

Syntax

➔ **rmnode** — **|rmnodecanister** -force **-deactivatespare** object_id object_name

Parameters

-force

(Optional) Overrides the checks that this command runs. The parameter overrides the following two checks:

- If the command results in volumes going offline, the command fails unless the **force** parameter is used.
- If the command results in a loss of data because there is unwritten data in the write cache that is contained only within the node or node canister to be removed, the command fails unless the **force** parameter is used.

If you use the **force** parameter as a result of an error about volumes going offline, you force the node or node canister removal and run the risk of losing data from the write cache. The **force** parameter should always be used with caution.

-deactivatespare

(Optional) Specifies that the spare node (for this node) must be deactivated.

Important: Do not remove an offline node while a spare node is active.

object_id / object_name

(Required) Specifies the object name or ID that you want to modify. The variable that follows the parameter is either:

- The object name that you assigned when you added the node to the clustered system
- The object ID that is assigned to the node (not the worldwide node name)

Description

This command removes a node or node canister from the clustered system. This makes the node or node canister a candidate to be added back into this clustered system or into another system. After the node or node canister is deleted, the other node in the I/O group enters write-through mode until another node or node canister is added back into the I/O group.

Attention: When you run the **rmnode** command to remove the configured hardware for a node:

- Small Computer System Interface-3 (SCSI-3) reservations (through that node) are removed
- Small Computer System Interface-3 (SCSI-3) registrations (through that node) are removed

By default, the **rmnode** / **rmnodecanister** command flushes the cache on the specified node before the node or node canister is taken offline. In some circumstances, such as when the system is already degraded (for example, when both nodes in the I/O group are online and the virtual disks within the I/O group are degraded), the system ensures that data loss does not occur as a result of deleting the only node or node canister with the cache data.

The cache is flushed before the node or node canister is deleted to prevent data loss if a failure occurs on the other node or node canister in the I/O group.

To take the specified node or node canister offline immediately without flushing the cache or ensuring data loss does not occur, run the **rmnode** / **rmnodecanister** command with the **-force** parameter.

Prerequisites:

Before you issue the **rmnode** / **rmnodecanister** command, perform the following tasks and read the following **Attention** notices to avoid losing access to data:

Attention:

1. Removing the last node in the cluster destroys the clustered system. Before you delete the last node or node canister in the clustered system, ensure that you want to destroy the clustered system.
2. If you are removing a single node or node canister and the remaining node or node canister in the I/O group is online, the data can be exposed to a single point of failure if the remaining node or node canister fails.
3. This command might take some time to complete since the cache in the I/O group for that node or node canister is flushed before the node or node canister is removed. If the **-force** parameter is used, the cache is not flushed and the command completes more quickly. However, if the deleted node or node canister is the last node or node canister in the I/O group, using the **-force** option results in the write cache for that node or node canister being discarded rather than flushed, and data loss can occur. The **-force** option should be used with caution.
4. If both nodes or node canisters in the I/O group are online and the volumes are already degraded before deleting the node or node canister, redundancy to the volumes is already degraded and loss of access to data and loss of data might occur if the **-force** option is used.

Notes:

1. If you are removing the configuration node or node canister, the **rmnode** / **rmnodecanister** command causes the configuration node or node canister to move to a different node or node canister within the clustered system. This process might take a short time: typically less than a minute. The clustered system IP address remains unchanged, but any SSH client attached to the configuration node or node canister might need to reestablish a connection. The management GUI reattaches to the new configuration node or node canister transparently.
2. If this is the last node or node canister in the clustered system or if it is currently assigned as the configuration node, all connections to the system are lost. The user interface and any open CLI sessions are lost if the last node or node canister in the clustered system is deleted. A time-out might occur if a command cannot be completed before the node or node canister is deleted.

An invocation example for rmnode

```
rmnode 1
```

The resulting output:

```
No feedback
```

An invocation example for rmnodecanister

```
rmnodecanister 1
```

The resulting output:

```
No feedback
```

An invocation example

```
rmnode -deactivatespare
```

The resulting output

No feedback

Related reference

[addnode \(SAN Volume Controller only\)](#)

Use the **addnode** command to add a new (candidate) node to an existing system. Enter this command any time after a system is created. If you are adding a node to a system, make sure that the model type of the new node is supported by the system code (code) version of the existing system. If the model type is not supported by the code, upgrade the system to a code version that supports the model type of the new node.

[addiscsistorageport](#)

Use the **addiscsistorageport** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any (or all) nodes in a specified I/O group (or the entire clustered system) to a discovered backend target iSCSI controller.

[cfgportip](#)

Use the **cfgportip** command to assign an Internet Protocol (IP) address to each node Ethernet port for Internet Small Computer System Interface (iSCSI) input/output (I/O).

[chbanner](#)

Use the **chbanner** command to configure the login message that is displayed during CLI Secure Shell (SSH) login.

[chportib](#)

Use the **chportib** command to assign an Internet Protocol (IP) address to each node Ethernet port for NVMe for InfiniBand ports.

[chcluster \(Discontinued\)](#)

Attention: The **chcluster** command has been discontinued. Use the **chsystem** command instead.

[chiogrp](#)

Use the **chiogrp** command to modify the name of an I/O group, or the amount of memory that is available for RAID arrays, Copy Services, FlashCopy services, or volume mirroring operations.

[chiscsistorageport](#)

Use the **chiscsistorageport** command to change authentication parameters, such as setting authentication credentials, removing authentication parameters, or updating credentials.

[chiscsiportauth](#)

Use the **chiscsiportauth** command to set or configure the iSCSI Initiator authentication or authorization information that is used to connect to the backend IBM Cloud storage. This command is for IBM Spectrum Virtualize for Public Cloud only.

[chnode](#)

Use the **chnode** / **chnodecanister** command to change the name that is assigned to a node or node canister as well as other options. You can then use the new name when running subsequent commands. All parameters that are associated with this command are optional. However, you must specify one or more parameters.

[chnodebattery](#)

Use the **chnodebattery** command to set or clear the light-emitting diode (LED) on a hot-swappable battery (in a node).

[chnodebootdrive](#)

Use the **chnodebootdrive** command to change a drive or synchronize the drives on a system if a drive or field-replaceable unit (FRU) replacement drive breaks.

[chnodehw \(SVC\) / chnodecanisterhw \(Storwize family products\)](#)

Use the **chnodehw** / **chnodecanisterhw** command to update the hardware configuration for a node or node canister.

[chquorum](#)

Use the **chquorum** command to change the quorum association.

chsecurity

Use the **chsecurity** command to change the Secure Sockets Layer (SSL), Secure Shell (SSH), or Transport Layer Security (TLS) security settings for a system.

chsite

Use the **chsite** command to change the site name.

chsra

Use the **chsra** command to configure support assistance.

chsystem

Use the **chsystem** command to modify the attributes of an existing system. Enter this command any time after a system is created. All the parameters that are associated with this command are optional. However, you must specify one or more parameters with this command.

chsystemcert

Use the **chsystemcert** command to manage the Secure Sockets Layer (SSL) certificate that is installed on a system.

chsystemip

Use the **chsystemip** command to modify the Internet Protocol (IP) configuration parameters for the system.

chsystemethernet

The **chsystemethernet** command is used to set the priority tag for host attachment, system, and storage traffic.

chthrottle

Use the **chthrottle** command to change attributes associated with a specified throttle object.

cleardumps

Use the **cleardumps** command to clear (or delete) the various dump directories on a specified node or node canister.

cpdumps

Use the **cpdumps** command to copy dump files from a nonconfiguration node onto the configuration node.

detectiscsistorageportcandidate

Use the **detectiscsistorageportcandidate** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any nodes in a specified I/O group to a discovered backend iSCSI target controller.

dumpconfig (Discontinued)

Attention: The **dumpconfig** command is discontinued.

help

Use the **help** (or **man**) command to display help information for system commands.

lsclustercandidate (Discontinued)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

lscluster (Discontinued)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

lsclusterip (Discontinued)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

lsclusterstats (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsiscsiportauth

Use the **lsiscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsiscsistorageport

Use the **lsiscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsiscsistorageportcandidate

Use the **lsiscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrphost

Use the **lsiogrphost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode/ lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

ls_timezone

Use the **ls_timezone** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **set_timezone** command to set the time zone.

ls_sasportcandidate

Use the **ls_sasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

ls_security

Use the **ls_security** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

ls_site

Use the **ls_site** command to report the names of the sites.

ls_sra

Use the **ls_sra** command to check both secure remote assistance status and the time of the last login.

ls_throttle

Use the **ls_throttle** command to list throttle objects that are configured in the clustered system.

ls_system

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

[stopcluster](#) (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

[stopsystem](#)

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

[swapnode](#)

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

Syntax

```
➔ rmportip -failover -ip_6 -node node_name node_id port_id ➔
```

Parameters

-failover

(Optional) Specifies that the failover IP address information is removed for the specified port.

-ip_6

(Optional) Specifies that the Internet Protocol Version 6 (IPv6) address is removed for the specified port. If this parameter is not used, the Internet Protocol Version 4 (IPv4) address is removed by default.

-node node_name / node_id

(Required) Specifies the node with the Ethernet port that the IP address is being removed from.

port_id

(Required) Specifies which port (1, 2, 3, or 4) to apply changes to.

Description

This command removes an IPv4 or IPv6 address from an Ethernet port of a node.

Before you unconfigure an IP from a source Ethernet port, the system checks whether any sessions are established from the selected port to any back-end iSCSI controller. You must remove sessions to the back-end iSCSI controller by using the command before you attempt to unconfigure the port. When the last IP (IPv4 or IPv6) address on a port is removed, the host port group ID that is associated with an iSCSI port is removed.

An invocation example for IPv4

```
rmportip -node 1 1
```

The resulting output:

```
No feedback
```

An invocation example for IPv6

```
rmportip -node 1 -ip_6 2
```

The resulting output:

No feedback

Use the **chiscsiportauth** command to set or configure the iSCSI Initiator authentication or authorization information that is used to connect to the backend IBM Cloud storage. This command is for IBM Spectrum Virtualize for Public Cloud only.

chnode

Use the **chnode** / **chnodecanister** command to change the name that is assigned to a node or node canister as well as other options. You can then use the new name when running subsequent commands. All parameters that are associated with this command are optional. However, you must specify one or more parameters.

chnodebattery

Use the **chnodebattery** command to set or clear the light-emitting diode (LED) on a hot-swappable battery (in a node).

chnodebootdrive

Use the **chnodebootdrive** command to change a drive or synchronize the drives on a system if a drive or field-replaceable unit (FRU) replacement drive breaks.

chnodehw (SVC) / chnodecanisterhw (Storwize family products)

Use the **chnodehw** / **chnodecanisterhw** command to update the hardware configuration for a node or node canister.

chquorum

Use the **chquorum** command to change the quorum association.

chsecurity

Use the **chsecurity** command to change the Secure Sockets Layer (SSL), Secure Shell (SSH), or Transport Layer Security (TLS) security settings for a system.

chsite

Use the **chsite** command to change the site name.

chsra

Use the **chsra** command to configure support assistance.

chsystem

Use the **chsystem** command to modify the attributes of an existing system. Enter this command any time after a system is created. All the parameters that are associated with this command are optional. However, you must specify one or more parameters with this command.

chsystemcert

Use the **chsystemcert** command to manage the Secure Sockets Layer (SSL) certificate that is installed on a system.

chsystemip

Use the **chsystemip** command to modify the Internet Protocol (IP) configuration parameters for the system.

chsystemethernet

The **chsystemethernet** command is used to set the priority tag for host attachment, system, and storage traffic.

chthrottle

Use the **chthrottle** command to change attributes associated with a specified throttle object.

cleardumps

Use the **cleardumps** command to clear (or delete) the various dump directories on a specified node or node canister.

cpdumps

Use the **cpdumps** command to copy dump files from a nonconfiguration node onto the configuration node.

detectiscsistorageportcandidate

Use the **detectiscsistorageportcandidate** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any nodes in a specified I/O group to a discovered backend iSCSI target controller.

dumpconfig (Discontinued)

Attention: The **dumpconfig** command is discontinued.

help

Use the **help** (or **man**) command to display help information for system commands.

lsclustercandidate (Discontinued)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

lscluster (Discontinued)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

lsclusterip (Discontinued)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

lsclusterstats (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsiscsiportauth

Use the **lsiscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsiscsistorageport

Use the **lsiscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsiscsistorageportcandidate

Use the **lsiscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrphost

Use the **lsiogrphost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode/ lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

ls_timezone

Use the **ls_timezone** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **set_timezone** command to set the time zone.

ls_sasportcandidate

Use the **ls_sasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

ls_security

Use the **ls_security** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

ls_site

Use the **ls_site** command to report the names of the sites.

ls_sra

Use the **ls_sra** command to check both secure remote assistance status and the time of the last login.

ls_throttle

Use the **ls_throttle** command to list throttle objects that are configured in the clustered system.

ls_system

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

[stopcluster](#) (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

[stopsystem](#)

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

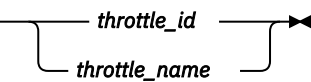

[swapnode](#)

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

Syntax

➤ **rmthrottle** 

Parameters

throttle_id* / *throttle_name

(Required) Specifies the throttle object ID or name. The value must be a numeric or alphanumeric string up to 63 characters long.

Description

This command removes the throttle object associated with a specified volume.

An invocation example to remove a throttle object with the ID 2

```
rmthrottle 2
```

The detailed resulting output:

```
No feedback
```

An invocation example to remove a throttle object with name throttle_vdisk2

```
rmthrottle throttle_vdisk2
```

The detailed resulting output:

```
No feedback
```

Related reference

[addnode](#) (SAN Volume Controller only)

Use the **addnode** command to add a new (candidate) node to an existing system. Enter this command any time after a system is created. If you are adding a node to a system, make sure that the model type of the new node is supported by the system code (code) version of the existing system. If the model type is not supported by the code, upgrade the system to a code version that supports the model type of the new node.

[addiscsistorageport](#)

Use the **addiscsistorageport** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any (or all) nodes in a specified I/O group (or the entire clustered system) to a discovered backend target iSCSI controller.

cfgportip

Use the **cfgportip** command to assign an Internet Protocol (IP) address to each node Ethernet port for Internet Small Computer System Interface (iSCSI) input/output (I/O).

chbanner

Use the **chbanner** command to configure the login message that is displayed during CLI Secure Shell (SSH) login.

chportib

Use the **chportib** command to assign an Internet Protocol (IP) address to each node Ethernet port for NVMe for InfiniBand ports.

chcluster (Discontinued)

Attention: The **chcluster** command has been discontinued. Use the **chsystem** command instead.

chiogrp

Use the **chiogrp** command to modify the name of an I/O group, or the amount of memory that is available for RAID arrays, Copy Services, FlashCopy services, or volume mirroring operations.

chiscsistorageport

Use the **chiscsistorageport** command to change authentication parameters, such as setting authentication credentials, removing authentication parameters, or updating credentials.

chiscsiportauth

Use the **chiscsiportauth** command to set or configure the iSCSI Initiator authentication or authorization information that is used to connect to the backend IBM Cloud storage. This command is for IBM Spectrum Virtualize for Public Cloud only.

chnode

Use the **chnode** / **chnodecanister** command to change the name that is assigned to a node or node canister as well as other options. You can then use the new name when running subsequent commands. All parameters that are associated with this command are optional. However, you must specify one or more parameters.

chnodebattery

Use the **chnodebattery** command to set or clear the light-emitting diode (LED) on a hot-swappable battery (in a node).

chnodebootdrive

Use the **chnodebootdrive** command to change a drive or synchronize the drives on a system if a drive or field-replaceable unit (FRU) replacement drive breaks.

chnodehw (SVC) / chnodecanisterhw (Storwize family products)

Use the **chnodehw** / **chnodecanisterhw** command to update the hardware configuration for a node or node canister.

chquorum

Use the **chquorum** command to change the quorum association.

chsecurity

Use the **chsecurity** command to change the Secure Sockets Layer (SSL), Secure Shell (SSH), or Transport Layer Security (TLS) security settings for a system.

chsite

Use the **chsite** command to change the site name.

chsr

Use the **chsr** command to configure support assistance.

chsystem

Use the **chsystem** command to modify the attributes of an existing system. Enter this command any time after a system is created. All the parameters that are associated with this command are optional. However, you must specify one or more parameters with this command.

chsystemcert

Use the **chsystemcert** command to manage the Secure Sockets Layer (SSL) certificate that is installed on a system.

chsystemip

Use the **chsystemip** command to modify the Internet Protocol (IP) configuration parameters for the system.

chsystemethernet

The **chsystemethernet** command is used to set the priority tag for host attachment, system, and storage traffic.

chthrottle

Use the **chthrottle** command to change attributes associated with a specified throttle object.

cleardumps

Use the **cleardumps** command to clear (or delete) the various dump directories on a specified node or node canister.

cpdumps

Use the **cpdumps** command to copy dump files from a nonconfiguration node onto the configuration node.

detectiscsistorageportcandidate

Use the **detectiscsistorageportcandidate** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any nodes in a specified I/O group to a discovered backend iSCSI target controller.

dumpconfig (Discontinued)

Attention: The **dumpconfig** command is discontinued.

help

Use the **help** (or **man**) command to display help information for system commands.

lsclustercandidate (Discontinued)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

lscluster (Discontinued)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

lsclusterip (Discontinued)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

lsclusterstats (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsiscsiportauth

Use the **lsiscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsiscsistorageport

Use the **lsiscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsiscsistorageportcandidate

Use the **lsiscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrphost

Use the **lsiogrphost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode**/**lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lszones

Use the **lszones** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

stopcluster (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

stopsystem

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

swapnode

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setssystemtime** command instead.

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

[lsclusterstats](#) (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lscsiportauth

Use the **lscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lscsisstorageport

Use the **lscsisstorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lscsisstorageportcandidate

Use the **lscsisstorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrphost

Use the **lsiogrphost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode**/ **lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lstimezones

Use the **lstimezones** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

[stopcluster](#) (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

[stopsystem](#)

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

[swapnode](#)

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

setssystemtime

Use the **setssystemtime** command to set the time for the system.

Syntax

➤ **setssystemtime** — **-time** — *time_value* ➤

Parameters

-time *time_value*

(Required) Specifies the time to which the system must be set. This value must be in the following format (where M is month, D is day, H is hour, m is minute, and Y is year):

MMDDHHmmYYYY

Description

This command sets the time for the system.

Note: Do not manually set the time for Amazon Web Services (AWS). The system time is synced with the AWS NTP server during installation.

An invocation example

```
setssystemtime -time 040509142003
```

The resulting output

```
No feedback
```

Related reference

[addnode](#) (SAN Volume Controller only)

Use the **addnode** command to add a new (candidate) node to an existing system. Enter this command any time after a system is created. If you are adding a node to a system, make sure that the model type of the new node is supported by the system code (code) version of the existing system. If the model type is not supported by the code, upgrade the system to a code version that supports the model type of the new node.

[addiscsistorageport](#)

Use the **addiscsistorageport** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any (or all) nodes in a specified I/O group (or the entire clustered system) to a discovered backend target iSCSI controller.

[cfgportip](#)

Use the **cfgportip** command to assign an Internet Protocol (IP) address to each node Ethernet port for Internet Small Computer System Interface (iSCSI) input/output (I/O).

[chbanner](#)

Use the **chbanner** command to configure the login message that is displayed during CLI Secure Shell (SSH) login.

chportib

Use the **chportib** command to assign an Internet Protocol (IP) address to each node Ethernet port for NVMe for InfiniBand ports.

chcluster (Discontinued)

Attention: The **chcluster** command has been discontinued. Use the **chsystem** command instead.

chiogrp

Use the **chiogrp** command to modify the name of an I/O group, or the amount of memory that is available for RAID arrays, Copy Services, FlashCopy services, or volume mirroring operations.

chiscsistorageport

Use the **chiscsistorageport** command to change authentication parameters, such as setting authentication credentials, removing authentication parameters, or updating credentials.

chiscsiportauth

Use the **chiscsiportauth** command to set or configure the iSCSI Initiator authentication or authorization information that is used to connect to the backend IBM Cloud storage. This command is for IBM Spectrum Virtualize for Public Cloud only.

chnode

Use the **chnode** / **chnodecanister** command to change the name that is assigned to a node or node canister as well as other options. You can then use the new name when running subsequent commands. All parameters that are associated with this command are optional. However, you must specify one or more parameters.

chnodebattery

Use the **chnodebattery** command to set or clear the light-emitting diode (LED) on a hot-swappable battery (in a node).

chnodebootdrive

Use the **chnodebootdrive** command to change a drive or synchronize the drives on a system if a drive or field-replaceable unit (FRU) replacement drive breaks.

chnodehw (SVC) / chnodecanisterhw (Storwize family products)

Use the **chnodehw** / **chnodecanisterhw** command to update the hardware configuration for a node or node canister.

chquorum

Use the **chquorum** command to change the quorum association.

chsecurity

Use the **chsecurity** command to change the Secure Sockets Layer (SSL), Secure Shell (SSH), or Transport Layer Security (TLS) security settings for a system.

chsite

Use the **chsite** command to change the site name.

chsra

Use the **chsra** command to configure support assistance.

chsystem

Use the **chsystem** command to modify the attributes of an existing system. Enter this command any time after a system is created. All the parameters that are associated with this command are optional. However, you must specify one or more parameters with this command.

chsystemcert

Use the **chsystemcert** command to manage the Secure Sockets Layer (SSL) certificate that is installed on a system.

chsystemip

Use the **chsystemip** command to modify the Internet Protocol (IP) configuration parameters for the system.

chsystemethernet

The **chsystemethernet** command is used to set the priority tag for host attachment, system, and storage traffic.

chthrottle

Use the **chthrottle** command to change attributes associated with a specified throttle object.

cleardumps

Use the **cleardumps** command to clear (or delete) the various dump directories on a specified node or node canister.

cpdumps

Use the **cpdumps** command to copy dump files from a nonconfiguration node onto the configuration node.

detectiscsistorageportcandidate

Use the **detectiscsistorageportcandidate** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any nodes in a specified I/O group to a discovered backend iSCSI target controller.

dumpconfig (Discontinued)

Attention: The **dumpconfig** command is discontinued.

help

Use the **help** (or **man**) command to display help information for system commands.

lsclustercandidate (Discontinued)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

lscluster (Discontinued)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

lsclusterip (Discontinued)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

lsclusterstats (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsiscsiportauth

Use the **lsiscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsiscsistorageport

Use the **lsiscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsiscsistorageportcandidate

Use the **lsiscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrphost

Use the **lsiogrphost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode**/**lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lstimezones

Use the **lstimezones** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstartportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

stopcluster (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

stopsystem

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

swapnode

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

Syntax

Parameters

-disable

Disables the password-reset feature that is available through the USB flash drive interface.

-enable

Enables the password-reset feature that is available through the USB flash drive interface.

-show

Displays the status of the password-reset feature, which is either enabled or disabled.

Description

The system provides an option to reset the system superuser password to the default value. For all systems, this option can be done by using the USB flash drive interface. If this feature remains enabled, make sure that there is adequate physical security to the system hardware. If this feature is disabled, it is not possible to reset the superuser password by using a USB flash drive. You can view or change the status of this feature.

An invocation example

```
setpwdreset -show
```

The resulting output:

```
Password status: [1]
```

This output means that the password or reset feature is enabled. If the password status is [0], this feature is disabled.

[addnode \(SAN Volume Controller only\)](#)

Use the **addnode** command to add a new (candidate) node to an existing system. Enter this command any time after a system is created. If you are adding a node to a system, make sure that the model type of the new node is supported by the system code (code) version of the existing system. If the model type is not supported by the code, upgrade the system to a code version that supports the model type of the new node.

[addiscsistorageport](#)

Use the **addiscsistorageport** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any (or all) nodes in a specified I/O group (or the entire clustered system) to a discovered backend target iSCSI controller.

[cfgportip](#)

Use the **cfgportip** command to assign an Internet Protocol (IP) address to each node Ethernet port for Internet Small Computer System Interface (iSCSI) input/output (I/O).

chbanner

Use the **chbanner** command to configure the login message that is displayed during CLI Secure Shell (SSH) login.

chportib

Use the **chportib** command to assign an Internet Protocol (IP) address to each node Ethernet port for NVMe for InfiniBand ports.

chcluster (Discontinued)

Attention: The **chcluster** command has been discontinued. Use the **chsystem** command instead.

chiogrp

Use the **chiogrp** command to modify the name of an I/O group, or the amount of memory that is available for RAID arrays, Copy Services, FlashCopy services, or volume mirroring operations.

chiscsistorageport

Use the **chiscsistorageport** command to change authentication parameters, such as setting authentication credentials, removing authentication parameters, or updating credentials.

chiscsiportauth

Use the **chiscsiportauth** command to set or configure the iSCSI Initiator authentication or authorization information that is used to connect to the backend IBM Cloud storage. This command is for IBM Spectrum Virtualize for Public Cloud only.

chnode

Use the **chnode** / **chnodecanister** command to change the name that is assigned to a node or node canister as well as other options. You can then use the new name when running subsequent commands. All parameters that are associated with this command are optional. However, you must specify one or more parameters.

chnodebattery

Use the **chnodebattery** command to set or clear the light-emitting diode (LED) on a hot-swappable battery (in a node).

chnodebootdrive

Use the **chnodebootdrive** command to change a drive or synchronize the drives on a system if a drive or field-replaceable unit (FRU) replacement drive breaks.

chnodehw (SVC) / chnodecanisterhw (Storwize family products)

Use the **chnodehw** / **chnodecanisterhw** command to update the hardware configuration for a node or node canister.

chquorum

Use the **chquorum** command to change the quorum association.

chsecurity

Use the **chsecurity** command to change the Secure Sockets Layer (SSL), Secure Shell (SSH), or Transport Layer Security (TLS) security settings for a system.

chsite

Use the **chsite** command to change the site name.

chsra

Use the **chsra** command to configure support assistance.

chsystem

Use the **chsystem** command to modify the attributes of an existing system. Enter this command any time after a system is created. All the parameters that are associated with this command are optional. However, you must specify one or more parameters with this command.

chsystemcert

Use the **chsystemcert** command to manage the Secure Sockets Layer (SSL) certificate that is installed on a system.

chsystemip

Use the **chsystemip** command to modify the Internet Protocol (IP) configuration parameters for the system.

chsystemethernet

The **chsystemethernet** command is used to set the priority tag for host attachment, system, and storage traffic.

chthrottle

Use the **chthrottle** command to change attributes associated with a specified throttle object.

cleardumps

Use the **cleardumps** command to clear (or delete) the various dump directories on a specified node or node canister.

cpdumps

Use the **cpdumps** command to copy dump files from a nonconfiguration node onto the configuration node.

detectiscsistorageportcandidate

Use the **detectiscsistorageportcandidate** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any nodes in a specified I/O group to a discovered backend iSCSI target controller.

dumpconfig (Discontinued)

Attention: The **dumpconfig** command is discontinued.

help

Use the **help** (or **man**) command to display help information for system commands.

lsclustercandidate (Discontinued)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

lscluster (Discontinued)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

lsclusterip (Discontinued)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

lsclusterstats (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsiscsiportauth

Use the **lsiscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsiscsistorageport

Use the **lsscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsscsistorageportcandidate

Use the **lsscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrphost

Use the **lsiogrphost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode**/ **lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister.

Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lstimezone

Use the **lstimezone** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

settimezone

Use the **settimezone** command to set the time zone for the system.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

stopcluster (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

stopsystem

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

swapnode

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

settimezone

Use the **settimezone** command to set the time zone for the system.

Syntax

```
➤ settimezone — -timezone — timezone_arg ➤
```

Parameters

-timezone *timezone_arg*

Specifies the time zone to set for the system.

Description

(Optional) This command sets the time zone for the system. Use the **-timezone** parameter to specify the numeric ID of the time zone that you want to set. Issue the **lstimezones** command to list the time-zones that are available on the system. A list of valid time-zones settings is displayed in a list.

Set the time zone to use when formatting the event log that is produced by issuing `dumpperrlog`

Issue the **showtimezone** command to display the current time-zone settings for the system. The system ID and its associated time-zone are displayed. Issue the **setsystemtime** command to set the time for the system.

An invocation example

```
settimezone -timezone 5
```

The resulting output:

```
No feedback
```

Related reference

[addnode \(SAN Volume Controller only\)](#)

Use the **addnode** command to add a new (candidate) node to an existing system. Enter this command any time after a system is created. If you are adding a node to a system, make sure that the model type of the new node is supported by the system code (code) version of the existing system. If the model type is not supported by the code, upgrade the system to a code version that supports the model type of the new node.

[addiscsistorageport](#)

Use the **addiscsistorageport** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any (or all) nodes in a specified I/O group (or the entire clustered system) to a discovered backend target iSCSI controller.

[cfgportip](#)

Use the **cfgportip** command to assign an Internet Protocol (IP) address to each node Ethernet port for Internet Small Computer System Interface (iSCSI) input/output (I/O).

[chbanner](#)

Use the **chbanner** command to configure the login message that is displayed during CLI Secure Shell (SSH) login.

[chportib](#)

Use the **chportib** command to assign an Internet Protocol (IP) address to each node Ethernet port for NVMe for InfiniBand ports.

[chcluster \(Discontinued\)](#)

Attention: The **chcluster** command has been discontinued. Use the **chsystem** command instead.

chiogrp

Use the **chiogrp** command to modify the name of an I/O group, or the amount of memory that is available for RAID arrays, Copy Services, FlashCopy services, or volume mirroring operations.

chiscsistorageport

Use the **chiscsistorageport** command to change authentication parameters, such as setting authentication credentials, removing authentication parameters, or updating credentials.

chiscsiportauth

Use the **chiscsiportauth** command to set or configure the iSCSI Initiator authentication or authorization information that is used to connect to the backend IBM Cloud storage. This command is for IBM Spectrum Virtualize for Public Cloud only.

chnode

Use the **chnode** / **chnodecanister** command to change the name that is assigned to a node or node canister as well as other options. You can then use the new name when running subsequent commands. All parameters that are associated with this command are optional. However, you must specify one or more parameters.

chnodebattery

Use the **chnodebattery** command to set or clear the light-emitting diode (LED) on a hot-swappable battery (in a node).

chnodebootdrive

Use the **chnodebootdrive** command to change a drive or synchronize the drives on a system if a drive or field-replaceable unit (FRU) replacement drive breaks.

chnodehw (SVC) / chnodecanisterhw (Storwize family products)

Use the **chnodehw** / **chnodecanisterhw** command to update the hardware configuration for a node or node canister.

chquorum

Use the **chquorum** command to change the quorum association.

chsecurity

Use the **chsecurity** command to change the Secure Sockets Layer (SSL), Secure Shell (SSH), or Transport Layer Security (TLS) security settings for a system.

chsite

Use the **chsite** command to change the site name.

chsra

Use the **chsra** command to configure support assistance.

chsystem

Use the **chsystem** command to modify the attributes of an existing system. Enter this command any time after a system is created. All the parameters that are associated with this command are optional. However, you must specify one or more parameters with this command.

chsystemcert

Use the **chsystemcert** command to manage the Secure Sockets Layer (SSL) certificate that is installed on a system.

chsystemip

Use the **chsystemip** command to modify the Internet Protocol (IP) configuration parameters for the system.

chsystemethernet

The **chsystemethernet** command is used to set the priority tag for host attachment, system, and storage traffic.

chthrottle

Use the **chthrottle** command to change attributes associated with a specified throttle object.

cleardumps

Use the **cleardumps** command to clear (or delete) the various dump directories on a specified node or node canister.

cpdumps

Use the **cpdumps** command to copy dump files from a nonconfiguration node onto the configuration node.

detectiscsistorageportcandidate

Use the **detectiscsistorageportcandidate** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any nodes in a specified I/O group to a discovered backend iSCSI target controller.

dumpconfig (Discontinued)

Attention: The **dumpconfig** command is discontinued.

help

Use the **help** (or **man**) command to display help information for system commands.

lsclustercandidate (Discontinued)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

lscluster (Discontinued)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

lsclusterip (Discontinued)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

lsclusterstats (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsiscsiportauth

Use the **lsiscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsiscsistorageport

Use the **lsiscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsiscsistorageportcandidate

Use the **lsiscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrphost

Use the **lsiogrphost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode**/**lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lstimezones

Use the **lstimezones** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

stopcluster (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

stopsystem

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

swapnode

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

Syntax

➤ **showtimezone**  **-nohdr** **-delim** *delimiter*

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum possible width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a one-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified character.

Description

This command displays a single time zone and its associated ID. This is the current time zone setting for the cluster. A list of available time-zones can be viewed by running the **lstimezones** command. The time zone can be changed by running the **settimezone** command.

An invocation example

```
showtimezone -delim :
```

The resulting output:

```
id:timezone
522:UTC
```

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode**/**lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lstimezones

Use the **lstimezones** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

stopcluster (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

stopsystem

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

swapnode

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

Syntax

➤ **startstats** — *-interval* — *time_in_minutes* ➤

Parameters

-interval *time_in_minutes*

(Required) Specifies the time in minutes. This time interval is the interval between the gathering of statistics, 1 - 60 minutes in increments of 1 minute.

Description

Running the **startstats** command resets the statistics timer to zero, and give it a new interval at which to sample. Statistics are collected at the end of each sampling period as specified by the **-interval** parameter. These statistics are written to a file, with a new file created at the end of each sampling period. Separate files are created for MDisks, volumes, and node statistics.

The files generated are written to the `/dumps/iostats` directory.

A maximum of 16 files are stored in the directory at any one time for each statistics file type, for example:

```
Nm_stats_nodepanelname_date_time  
Nv_stats_nodepanelname_date_time  
Nn_stats_nodepanelname_date_time
```

Statistics files are created for all time intervals. Before the 17th file for each type is created, the oldest file of that type is deleted.

These files can be listed by using the **lsdumps** command.

The following naming convention is used for these files:

stats_type_stats_nodepanelname_date_time

Where:

- The value for *stats_type* is Nm for MDisks, Nv for volumes, and Nn for node statistics.
- The value for *nodepanelname* is the current configuration node panel name.
- The value for *date* is in the format of `yymmdd`.
- The value for *time* is in the format of `hhmmss`.

This an example of:

- An MDisk statistics file name: `Nm_stats_000229_031123_072426`
- A volume statistics file name: `Nv_stats_000229_031123_072426`
- A node statistics file name: `Nn_stats_000229_031123_072426`

Statistics are collected for each MDisk and recorded in the `Nm_stats_nodepanelname_date_time` file, including the following statistical information:

- The number of SCSI read and write commands that are processed during the sample period
- The number of blocks of data that is read and written during the sample period
- Per MDisk, cumulative read and write external response times in milliseconds
- Per MDisk, cumulative read and write queued response times

Statistics are collected for each volume and recorded in the `Nv_stats_nodepanelname_date_time` file, including the following statistical information:

- The total number of processed SCSI read and write commands
- The total amount of read and written data
- Cumulative read and write response time in milliseconds
- Statistical information about the read or write cache usage
- Mirroring statistics that include latency

Statistics are collected for the node from which the statistics file originated, and those statistics are recorded in the `Nn_stats_nodepanelname_date_time` file, including the following statistical information:

- The usage figure for the node from which the statistic file was obtained
- The amount of data that is transferred to and received from each port on the node to other devices on the SAN

- Any statistical information about communication to other nodes on the fabric

An invocation example

```
startstats -interval 25
```

The resulting output:

```
No feedback
```

Related reference

[addnode \(SAN Volume Controller only\)](#)

Use the **addnode** command to add a new (candidate) node to an existing system. Enter this command any time after a system is created. If you are adding a node to a system, make sure that the model type of the new node is supported by the system code (code) version of the existing system. If the model type is not supported by the code, upgrade the system to a code version that supports the model type of the new node.

[addiscsistorageport](#)

Use the **addiscsistorageport** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any (or all) nodes in a specified I/O group (or the entire clustered system) to a discovered backend target iSCSI controller.

[cfgportip](#)

Use the **cfgportip** command to assign an Internet Protocol (IP) address to each node Ethernet port for Internet Small Computer System Interface (iSCSI) input/output (I/O).

[chbanner](#)

Use the **chbanner** command to configure the login message that is displayed during CLI Secure Shell (SSH) login.

[chportib](#)

Use the **chportib** command to assign an Internet Protocol (IP) address to each node Ethernet port for NVMe for InfiniBand ports.

[chcluster \(Discontinued\)](#)

Attention: The **chcluster** command has been discontinued. Use the **chsystem** command instead.

[chiogrp](#)

Use the **chiogrp** command to modify the name of an I/O group, or the amount of memory that is available for RAID arrays, Copy Services, FlashCopy services, or volume mirroring operations.

[chiscsistorageport](#)

Use the **chiscsistorageport** command to change authentication parameters, such as setting authentication credentials, removing authentication parameters, or updating credentials.

[chiscsiportauth](#)

Use the **chiscsiportauth** command to set or configure the iSCSI Initiator authentication or authorization information that is used to connect to the backend IBM Cloud storage. This command is for IBM Spectrum Virtualize for Public Cloud only.

[chnode](#)

Use the **chnode** / **chnodecanister** command to change the name that is assigned to a node or node canister as well as other options. You can then use the new name when running subsequent commands. All parameters that are associated with this command are optional. However, you must specify one or more parameters.

[chnodebattery](#)

Use the **chnodebattery** command to set or clear the light-emitting diode (LED) on a hot-swappable battery (in a node).

[chnodebootdrive](#)

Use the **chnodebootdrive** command to change a drive or synchronize the drives on a system if a drive or field-replaceable unit (FRU) replacement drive breaks.

[chnodehw \(SVC\) / chnodecanisterhw \(Storwize family products\)](#)

Use the **chnodehw** / **chnodecanisterhw** command to update the hardware configuration for a node or node canister.

[chquorum](#)

Use the **chquorum** command to change the quorum association.

[chsecurity](#)

Use the **chsecurity** command to change the Secure Sockets Layer (SSL), Secure Shell (SSH), or Transport Layer Security (TLS) security settings for a system.

[chsite](#)

Use the **chsite** command to change the site name.

[chusra](#)

Use the **chusra** command to configure support assistance.

[chsystem](#)

Use the **chsystem** command to modify the attributes of an existing system. Enter this command any time after a system is created. All the parameters that are associated with this command are optional. However, you must specify one or more parameters with this command.

[chsystemcert](#)

Use the **chsystemcert** command to manage the Secure Sockets Layer (SSL) certificate that is installed on a system.

[chsystemip](#)

Use the **chsystemip** command to modify the Internet Protocol (IP) configuration parameters for the system.

[chsystemethernet](#)

The **chsystemethernet** command is used to set the priority tag for host attachment, system, and storage traffic.

[chthrottle](#)

Use the **chthrottle** command to change attributes associated with a specified throttle object.

[cleardumps](#)

Use the **cleardumps** command to clear (or delete) the various dump directories on a specified node or node canister.

[cpdumps](#)

Use the **cpdumps** command to copy dump files from a nonconfiguration node onto the configuration node.

[detectiscsistorageportcandidate](#)

Use the **detectiscsistorageportcandidate** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any nodes in a specified I/O group to a discovered backend iSCSI target controller.

[dumpconfig \(Discontinued\)](#)

Attention: The **dumpconfig** command is discontinued.

[help](#)

Use the **help** (or **man**) command to display help information for system commands.

[lsclustercandidate \(Discontinued\)](#)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

[lscluster \(Discontinued\)](#)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

[lsclusterip \(Discontinued\)](#)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

lsclusterstats (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsiscsiportauth

Use the **lsiscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsiscsistorageport

Use the **lsiscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsiscsistorageportcandidate

Use the **lsiscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrpghost

Use the **lsiogrpghost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode/ lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lstimezone

Use the **lstimezone** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

[showtimezone](#)

Use the **showtimezone** command to display the current time zone settings for the cluster.

[stopstats \(Deprecated\)](#)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

[stopcluster \(Discontinued\)](#)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

[stopsystem](#)

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

[swapnode](#)

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

Related reference

[addnode \(SAN Volume Controller only\)](#)

Use the **addnode** command to add a new (candidate) node to an existing system. Enter this command any time after a system is created. If you are adding a node to a system, make sure that the model type of the new node is supported by the system code (code) version of the existing system. If the model type is not supported by the code, upgrade the system to a code version that supports the model type of the new node.

[addiscsistorageport](#)

Use the **addiscsistorageport** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any (or all) nodes in a specified I/O group (or the entire clustered system) to a discovered backend target iSCSI controller.

Use the **chiogrp** command to modify the name of an I/O group, or the amount of memory that is available for RAID arrays, Copy Services, FlashCopy services, or volume mirroring operations.

[chiscsistorageport](#)

Use the **chiscsistorageport** command to change authentication parameters, such as setting authentication credentials, removing authentication parameters, or updating credentials.

[chiscsiportauth](#)

Use the **chiscsiportauth** command to set or configure the iSCSI Initiator authentication or authorization information that is used to connect to the backend IBM Cloud storage. This command is for IBM Spectrum Virtualize for Public Cloud only.

[chnode](#)

Use the **chnode** / **chnodecanister** command to change the name that is assigned to a node or node canister as well as other options. You can then use the new name when running subsequent commands.

All parameters that are associated with this command are optional. However, you must specify one or more parameters.

chnodebattery

Use the **chnodebattery** command to set or clear the light-emitting diode (LED) on a hot-swappable battery (in a node).

chnodebootdrive

Use the **chnodebootdrive** command to change a drive or synchronize the drives on a system if a drive or field-replaceable unit (FRU) replacement drive breaks.

chnodehw (SVC) / chnodecanisterhw (Storwize family products)

Use the **chnodehw** / **chnodecanisterhw** command to update the hardware configuration for a node or node canister.

chquorum

Use the **chquorum** command to change the quorum association.

chsecurity

Use the **chsecurity** command to change the Secure Sockets Layer (SSL), Secure Shell (SSH), or Transport Layer Security (TLS) security settings for a system.

chsite

Use the **chsite** command to change the site name.

chsra

Use the **chsra** command to configure support assistance.

chsystem

Use the **chsystem** command to modify the attributes of an existing system. Enter this command any time after a system is created. All the parameters that are associated with this command are optional. However, you must specify one or more parameters with this command.

chsystemcert

Use the **chsystemcert** command to manage the Secure Sockets Layer (SSL) certificate that is installed on a system.

chsystemip

Use the **chsystemip** command to modify the Internet Protocol (IP) configuration parameters for the system.

chsystemethernet

The **chsystemethernet** command is used to set the priority tag for host attachment, system, and storage traffic.

chthrottle

Use the **chthrottle** command to change attributes associated with a specified throttle object.

cleardumps

Use the **cleardumps** command to clear (or delete) the various dump directories on a specified node or node canister.

cpdumps

Use the **cpdumps** command to copy dump files from a nonconfiguration node onto the configuration node.

detectiscsistorageportcandidate

Use the **detectiscsistorageportcandidate** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any nodes in a specified I/O group to a discovered backend iSCSI target controller.

dumpconfig (Discontinued)

Attention: The **dumpconfig** command is discontinued.

help

Use the **help** (or **man**) command to display help information for system commands.

Isclustercandidate (Discontinued)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

lscluster (Discontinued)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

lsclusterip (Discontinued)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

lsclusterstats (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsiscsiportauth

Use the **lsiscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsiscsistorageport

Use the **lsiscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsiscsistorageportcandidate

Use the **lsiscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrphost

Use the **lsiogrphost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode/ lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lstimezones

Use the **lstimezones** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setssystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopcluster (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopssystem** command instead.

stopssystem

Use the **stopssystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

swapnode

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

stopcluster (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopssystem** command instead.

Related reference

addnode (SAN Volume Controller only)

Use the **addnode** command to add a new (candidate) node to an existing system. Enter this command any time after a system is created. If you are adding a node to a system, make sure that the model type of the new node is supported by the system code (code) version of the existing system. If the model type is not supported by the code, upgrade the system to a code version that supports the model type of the new node.

addiscsistorageport

Use the **addiscsistorageport** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any (or all) nodes in a specified I/O group (or the entire clustered system) to a discovered backend target iSCSI controller.

cfgportip

Use the **cfgportip** command to assign an Internet Protocol (IP) address to each node Ethernet port for Internet Small Computer System Interface (iSCSI) input/output (I/O).

chbanner

Use the **chbanner** command to configure the login message that is displayed during CLI Secure Shell (SSH) login.

chportib

Use the **chportib** command to assign an Internet Protocol (IP) address to each node Ethernet port for NVMe for InfiniBand ports.

chcluster (Discontinued)

Attention: The **chcluster** command has been discontinued. Use the **chsystem** command instead.

chiogrp

Use the **chiogrp** command to modify the name of an I/O group, or the amount of memory that is available for RAID arrays, Copy Services, FlashCopy services, or volume mirroring operations.

chiscsistorageport

Use the **chiscsistorageport** command to change authentication parameters, such as setting authentication credentials, removing authentication parameters, or updating credentials.

chiscsiportauth

Use the **chiscsiportauth** command to set or configure the iSCSI Initiator authentication or authorization information that is used to connect to the backend IBM Cloud storage. This command is for IBM Spectrum Virtualize for Public Cloud only.

chnode

Use the **chnode** / **chnodecanister** command to change the name that is assigned to a node or node canister as well as other options. You can then use the new name when running subsequent commands. All parameters that are associated with this command are optional. However, you must specify one or more parameters.

chnodebattery

Use the **chnodebattery** command to set or clear the light-emitting diode (LED) on a hot-swappable battery (in a node).

chnodebootdrive

Use the **chnodebootdrive** command to change a drive or synchronize the drives on a system if a drive or field-replaceable unit (FRU) replacement drive breaks.

chnodehw (SVC) / chnodecanisterhw (Storwize family products)

Use the **chnodehw** / **chnodecanisterhw** command to update the hardware configuration for a node or node canister.

chquorum

Use the **chquorum** command to change the quorum association.

chsecurity

Use the **chsecurity** command to change the Secure Sockets Layer (SSL), Secure Shell (SSH), or Transport Layer Security (TLS) security settings for a system.

chsite

Use the **chsite** command to change the site name.

chsra

Use the **chsra** command to configure support assistance.

chsystem

Use the **chsystem** command to modify the attributes of an existing system. Enter this command any time after a system is created. All the parameters that are associated with this command are optional. However, you must specify one or more parameters with this command.

chsystemcert

Use the **chsystemcert** command to manage the Secure Sockets Layer (SSL) certificate that is installed on a system.

chsystemip

Use the **chsystemip** command to modify the Internet Protocol (IP) configuration parameters for the system.

chsystemethernet

The **chsystemethernet** command is used to set the priority tag for host attachment, system, and storage traffic.

chthrottle

Use the **chthrottle** command to change attributes associated with a specified throttle object.

cleardumps

Use the **cleardumps** command to clear (or delete) the various dump directories on a specified node or node canister.

cpdumps

Use the **cpdumps** command to copy dump files from a nonconfiguration node onto the configuration node.

detectiscsistorageportcandidate

Use the **detectiscsistorageportcandidate** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any nodes in a specified I/O group to a discovered backend iSCSI target controller.

dumpconfig (Discontinued)

Attention: The **dumpconfig** command is discontinued.

help

Use the **help** (or **man**) command to display help information for system commands.

lsclustercandidate (Discontinued)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

lscluster (Discontinued)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

lsclusterip (Discontinued)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

lsclusterstats (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsiscsiportauth

Use the **lsiscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsiscsistorageport

Use the **lsiscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsiscsistorageportcandidate

Use the **lsiscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrphost

Use the **lsiogrphost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode** / **lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lstimezones

Use the **lstimezones** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

stopsystem

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

swapnode

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

stopsystem

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

Syntax

Parameters

-force

(Optional) Specifies that the node that is being shut down is the last online node in a given I/O group. The **-force** parameter also overrides the checks that this command runs. The parameter overrides the following two checks:

- If the command results in volumes going offline, the command fails unless the **-force** parameter is used.

- If the node being shut down is the last online node in the I/O group, the command fails unless the **-force** parameter is used.

If you use the **-force** parameter as a result of an error about volumes going offline, you force the node to shut down, even if it is the last online node in the I/O group.

Remember: The **-force** parameter should always be used with caution.

-node *node_name* / *node_id*

(Optional) Specifies the node that you want to shut down. You can specify one of the following values:

- The node name or label that you assigned when you added the node to the system.
- The node ID that is assigned to the node (not the worldwide node name).

If you specify **-node *node_name* / *node_id***, only the specified node is shut down; otherwise, the entire system is shut down.

-reset

(Optional) Soft-resets a specified node. Must be used with **-node *node_id*/*node_name***.

Description

Use this command to shut down a single node or the entire clustered system in a controlled manner. You are prompted with a confirmation of intent (to process the command) when you specify this command.

For IBM Spectrum Virtualize for Public Cloud on Amazon Web Services (AWS), you must stop the EC2 instances on AWS after you use this command.

Attention: Do not power off the uninterruptible power supply or remove the power cable from the node.

If you need to shut down the system or a single node, use this command instead of using the power button on power supplies, or powering off the main power supplies to the system.

Before shutting down a node or system, complete the following requirements:

1. Quiesce all I/O operations that are destined for this node or system. If you do not quiesce these, failed I/O operations might be reported to your host operating systems.
2. Stop all FlashCopy, Metro Mirror, Global Mirror, and data migration operations.
3. Ensure that all asynchronous deletion operations have completed.

Using this command to shut down a single node fails if shutting down the node makes any volumes inaccessible, or if it is the last node in an I/O group. If you still need to shut down the node, you can use the **-force** option to override these checks.

An invocation example

```
stopsystem
```

The following confirmation prompt is displayed:

```
Are you sure that you want to continue with the shut down?
```

Select yes to confirm or no to cancel.

An invocation example

```
stopsystem -node 3
```

The following confirmation prompt is displayed:

```
Are you sure that you want to continue with the shut down?
```

Select yes to confirm or no to cancel.

[chsystemethernet](#)

The **chsystemethernet** command is used to set the priority tag for host attachment, system, and storage traffic.

[chthrottle](#)

Use the **chthrottle** command to change attributes associated with a specified throttle object.

[cleardumps](#)

Use the **cleardumps** command to clear (or delete) the various dump directories on a specified node or node canister.

[cpdumps](#)

Use the **cpdumps** command to copy dump files from a nonconfiguration node onto the configuration node.

[detectiscsistorageportcandidate](#)

Use the **detectiscsistorageportcandidate** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any nodes in a specified I/O group to a discovered backend iSCSI target controller.

[dumpconfig](#) (Discontinued)

Attention: The **dumpconfig** command is discontinued.

[help](#)

Use the **help** (or **man**) command to display help information for system commands.

[lsclustercandidate](#) (Discontinued)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

[lscluster](#) (Discontinued)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

[lsclusterip](#) (Discontinued)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

[lsclusterstats](#) (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

[lsdiscoverystatus](#)

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

[lsfabric](#)

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsscsiportauth

Use the **lsscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsscsistorageport

Use the **lsscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsscsistorageportcandidate

Use the **lsscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrphost

Use the **lsiogrphost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode**/ **lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lstimezone

Use the **lstimezone** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmportip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

stopcluster (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

swapnode

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

swapnode

Use the **swapnode** command to exchange and maintain nodes without interruption to the virtualized target ports associated with the specified node.

Syntax

Parameters

-replace | -failback | -failover | -service

(Required) Specifies whether to replace or service a selected node. The values are:

- **-replace** replaces a specified node that is in the offline or service state with a suitable candidate.
- **-failback** replaces a spare (that is being used) with the original node that it is replacing.
- **-failover** replaces a node with a spare even if it is online.
- **-service** puts a node into service state after the system triggers a failover because of any N_Port ID Virtualization (NPIV) ports.

-force

(Optional) Specifies that a node be removed, even if disruption to host system I/O might occur as a result.

Important: Specifying **-force** might result in a loss of access. Use it only under the direction of your product support information.

-spare node_id | node_name

(Optional) Specifies the ID or name of the spare node to use as a replacement. This parameter must be specified with **-failover**.

Note: The value for the ID must be greater than 1 because the spare is never the first node in the clustered system.

node_id | node_name

(Required) Specifies the node ID or name that is being swapped or serviced.

Description

This command exchanges and maintains nodes without interruption to the virtualized target ports associated with the specified node.

Specify **-replace** for the system to replace the name, I/O group, and site values associated with adding a node (by using the **addnode** command). These values are taken from the node that is being replaced. The existing node is explicitly specified, and a candidate node with the same WWNN value is chosen.

Remember: Specifying **-replace** might be used if you do not want to specify **rmnode** for an online node (which would delete the node from the clustered system).

Important: NVMe virtualized target ports are not supported on some Fibre Channel adapters. Before you use the CLI, check the spare node configuration.

An invocation example to replace an offline node

```
swapnode -replace 2
```

The detailed resulting output:

```
No feedback
```

An invocation example to replace node 2 with spare node 3

```
swapnode -failover -spare 3 2
```

The detailed resulting output:

```
No feedback
```

Related reference

[addnode \(SAN Volume Controller only\)](#)

Use the **addnode** command to add a new (candidate) node to an existing system. Enter this command any time after a system is created. If you are adding a node to a system, make sure that the model type of the new node is supported by the system code (code) version of the existing system. If the model type is not supported by the code, upgrade the system to a code version that supports the model type of the new node.

[addiscsistorageport](#)

Use the **addiscsistorageport** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any (or all) nodes in a specified I/O group (or the entire clustered system) to a discovered backend target iSCSI controller.

[cfgportip](#)

Use the **cfgportip** command to assign an Internet Protocol (IP) address to each node Ethernet port for Internet Small Computer System Interface (iSCSI) input/output (I/O).

[chbanner](#)

Use the **chbanner** command to configure the login message that is displayed during CLI Secure Shell (SSH) login.

[chportib](#)

Use the **chportib** command to assign an Internet Protocol (IP) address to each node Ethernet port for NVMe for InfiniBand ports.

[chcluster \(Discontinued\)](#)

Attention: The **chcluster** command has been discontinued. Use the **chsystem** command instead.

[chiogrp](#)

Use the **chiogrp** command to modify the name of an I/O group, or the amount of memory that is available for RAID arrays, Copy Services, FlashCopy services, or volume mirroring operations.

[chiscsistorageport](#)

Use the **chiscsistorageport** command to change authentication parameters, such as setting authentication credentials, removing authentication parameters, or updating credentials.

[chiscsiportauth](#)

Use the **chiscsiportauth** command to set or configure the iSCSI Initiator authentication or authorization information that is used to connect to the backend IBM Cloud storage. This command is for IBM Spectrum Virtualize for Public Cloud only.

chnode

Use the **chnode** / **chnodecanister** command to change the name that is assigned to a node or node canister as well as other options. You can then use the new name when running subsequent commands. All parameters that are associated with this command are optional. However, you must specify one or more parameters.

chnodebattery

Use the **chnodebattery** command to set or clear the light-emitting diode (LED) on a hot-swappable battery (in a node).

chnodebootdrive

Use the **chnodebootdrive** command to change a drive or synchronize the drives on a system if a drive or field-replaceable unit (FRU) replacement drive breaks.

chnodehw (SVC) / chnodecanisterhw (Storwize family products)

Use the **chnodehw** / **chnodecanisterhw** command to update the hardware configuration for a node or node canister.

chquorum

Use the **chquorum** command to change the quorum association.

chsecurity

Use the **chsecurity** command to change the Secure Sockets Layer (SSL), Secure Shell (SSH), or Transport Layer Security (TLS) security settings for a system.

chsite

Use the **chsite** command to change the site name.

chsra

Use the **chsra** command to configure support assistance.

chsystem

Use the **chsystem** command to modify the attributes of an existing system. Enter this command any time after a system is created. All the parameters that are associated with this command are optional. However, you must specify one or more parameters with this command.

chsystemcert

Use the **chsystemcert** command to manage the Secure Sockets Layer (SSL) certificate that is installed on a system.

chsystemip

Use the **chsystemip** command to modify the Internet Protocol (IP) configuration parameters for the system.

chsystemethernet

The **chsystemethernet** command is used to set the priority tag for host attachment, system, and storage traffic.

chthrottle

Use the **chthrottle** command to change attributes associated with a specified throttle object.

cleardumps

Use the **cleardumps** command to clear (or delete) the various dump directories on a specified node or node canister.

cpdumps

Use the **cpdumps** command to copy dump files from a nonconfiguration node onto the configuration node.

detectiscsistorageportcandidate

Use the **detectiscsistorageportcandidate** command to establish Internet Small Computer Systems Interface (iSCSI) login sessions from any nodes in a specified I/O group to a discovered backend iSCSI target controller.

dumpconfig (Discontinued)

Attention: The **dumpconfig** command is discontinued.

help

Use the **help** (or **man**) command to display help information for system commands.

lsclustercandidate (Discontinued)

Attention: The **lsclustercandidate** command has been discontinued. Use the **lspartnershipcandidate** command instead.

lscluster (Discontinued)

Attention: The **lscluster** command is discontinued. Use a combination of the **lspartnership**, **lspartnershipcandidate**, and **lssystem** commands instead.

lsclusterip (Discontinued)

Attention: The **lsclusterip** command has been discontinued. Use the **lssystemip** command instead.

lsclusterstats (Discontinued)

Attention: The **lsclusterstats** command is discontinued. Use the **lssystemstats** command instead.

lsdiscoverystatus

Use the **lsdiscoverystatus** command to determine whether a discovery operation is in progress.

lsfabric

Use the **lsfabric** command to generate a report that displays the Fibre Channel (FC) connectivity between nodes, controllers, and hosts.

lsnvmefabric

Use the **lsnvmefabric** command to display information about NVMe logins from configured hosts.

lsfcportcandidate

Use the **lsfcportcandidate** command to list the Fibre Channel (FC) ports. This information is used to find open FC ports.

lsiscsiportauth

Use the **lsiscsiportauth** command to display the per initiator port authentication and authorization information that is configured. This command is for IBM Spectrum Virtualize for Public Cloud only.

lsiscsistorageport

Use the **lsiscsistorageport** command to display the details of the iSCSI login sessions that are established from the initiator's iSCSI source ports to the iSCSI backend target controller ports.

lsiscsistorageportcandidate

Use the **lsiscsistorageportcandidate** command to display a concise or detailed list of information about the candidate Internet Small Computer Systems Interface (iSCSI) target controller iSCSI Qualified Name (IQN) that is specified with the target IP from the specified initiator source ports.

lsiogrp

Use the **lsiogrp** command to display a concise list or a detailed view of input/output (I/O) groups visible to the system.

lshbaportcandidate (Deprecated)

The **lshbaportcandidate** command is deprecated. Use either the **lsfcportcandidate** or **lssasportcandidate** command instead.

lsiogrphost

Use the **lsiogrphost** command to display a list of the hosts mapped to a specified I/O group.

lsiogrpcandidate

Use the **lsiogrpcandidate** command to list the I/O groups that can have nodes added to them.

lsiostatsdumps (Deprecated)

Attention: The **lsiostatsdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsiotracedumps (Deprecated)

Attention: The **lsiotracedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsnode (SVC) / lsnodecanister (Storwize family products)

Use the **lsnode**/**lsnodecanister** command to return a concise list or a detailed view of nodes or node canisters that are part of the system .

lsnodebattery

Use the **lsnodebattery** command to display information about the batteries in a node.

lsnodebootdrive

Use the **lsnodebootdrive** command to return information about the internal boot drives for nodes. This command applies to SAN Volume Controller 2145-DH8 systems.

lsnodecandidate (SAN Volume Controller)

Use the **lsnodecandidate** command to list all of the nodes that are available to add to the clustered system.

lsnodecanisterstats

The **lsnodecanisterstats** command displays the most recent values of all node canister statistics, and displays all node canister statistics for a particular canister. This command also can be used to display a history of values for a subset of available statistics.

lsnodedependentvdisks (Deprecated)

Attention: The **lsnodedependentvdisks** command is deprecated. Use the **lsdependentvdisks** command instead.

lsnodehw (SVC) / lsnodecanisterhw (Storwize family products)

Use the **lsnodehw** / **lsnodecanisterhw** command to display the configured and actual hardware configuration of nodes in the clustered system.

lsnodepsu

Use the **lsnodepsu** command to display the power supply unit information of nodes in a system.

lsnodestats (SVC) / lsnodecanisterstats (Storwize family products)

Use the **lsnodestats** / **lsnodecanisterstats** command to display the most recent values of statistics for all nodes or node canisters, and display all statistics for a particular node or node canister. Additionally, You can use this command to display a history of values for a given subset of available statistics.

lsnodevpd (SVC) / lsnodecanistervpd (Storwize family products)

Use the **lsnodevpd** / **lsnodecanistervpd** command to display the vital product data (VPD) for each node.

lsportusb

Use the **lsportusb** command to display information about Universal Serial Bus (USB) ports.

lsportip

Use the **lsportip** command to list the configuration for each Ethernet port on each node in the system. This command shows the Internet Protocol (IP) address and whether the port is configured as an Internet Small Computer Systems Interface (iSCSI) port.

lsportfc

Use the **lsportfc** command to view the status and properties of the Fibre Channel (FC) input/output (I/O) ports for the clustered system.

lsportsas

Use the **lsportsas** command to display the status of all SAS ports in the clustered system.

lsquorum

Use the **lsquorum** command to list the quorum devices that the system uses to store quorum data.

lsroute

Use the **lsroute** command to display the IP routing table.

lstimezones

Use the **lstimezones** command to list the time zones that are available on the system. Each time zone is assigned an ID that can be used in the **settimezone** command to set the time zone.

lssasportcandidate

Use the **lssasportcandidate** command to list the unconfigured serial-attached SCSI (SAS) ports that are logged in and available to add to the SAS worldwide port name (WWPN) or host objects.

lssecurity

Use the **lssecurity** command to display the current system Secure Sockets Layer (SSL) or Transport Layer Security (TLS) security settings.

lssite

Use the **lssite** command to report the names of the sites.

lssra

Use the **lssra** command to check both secure remote assistance status and the time of the last login.

lsthrottle

Use the **lsthrottle** command to list throttle objects that are configured in the clustered system.

lssystem

Use the **lssystem** command to display a detailed view of a system.

lssystemcert

Use the **lssystemcert** command to list information about the current system Secure Sockets Layer (SSL) certificate.

lssystemethernet

Use the **lssystemethernet** command to list system-wide Ethernet priority tag details for host attachment, system, and storage traffic.

lssystemip

Use the **lssystemip** command to display a list of the system management IP addresses configured for each port.

lssystemstats

Use the **lssystemstats** command to display the most recent values of all node statistics in a system, or to display a history of values for a specified subset of available statistics across all nodes in a system. This command also can be used to display a history of values for a specified subset of available statistics.

lstargetportfc

Use the **lstargetportfc** command to generate the lists of worldwide port names (WWPNs) required to set up Fibre Channel (FC) zoning and to display the current failover status of host I/O ports.

mkquorumapp

Use the **mkquorumapp** command to generate a Java application to use for quorum.

mkthrottle

Use the **mkthrottle** command to create a new throttle object and associate it with an object (such as a volume). You can also create offloaded I/O throttling (which is a single clustered system throttle).

ping

Use the **ping** command to diagnose IP configuration problems. The command checks whether the specified IP address is accessible from the node on which the command is run by using the specified IP address.

rmiscsistorageport

Use the **rmiscsistorageport** command to remove established Internet Small Computer Systems Interface (iSCSI) sessions between system nodes and backend iSCSI target.

rmnode (SVC) / rmnodecanister (Storwize family products)

The **rmnode** / **rmnodecanister** command deletes a node from the clustered system. You can enter this command any time after a clustered system has been created.

rmportip

Use the **rmporttip** command to remove an internet Small Computer System Interface (iSCSI) Internet Protocol (IP) address from a node Ethernet port.

rmthrottle

Use the **rmthrottle** command to remove the throttle object associated with any volume.

setclustertime (Discontinued)

Attention: The **setclustertime** command has been discontinued. Use the **setsystemtime** command instead.

setsystemtime

Use the **setsystemtime** command to set the time for the system.

setpwdreset

Use the **setpwdreset** command to view and change the status of the password-reset feature for the node.

settimezone

Use the **settimezone** command to set the time zone for the system.

showtimezone

Use the **showtimezone** command to display the current time zone settings for the cluster.

startstats

Use the **startstats** command to modify the interval at which per-node statistics for volumes, managed disks (MDisks), and nodes are collected.

stopstats (Deprecated)

The **stopstats** command is deprecated. You can no longer disable statistics collection.

stopcluster (Discontinued)

Attention: The **stopcluster** command is discontinued. Use the **stopsystem** command instead.

stopsystem

Use the **stopsystem** command to shut down a single node or the entire system in a controlled manner. When you issue this command, you are prompted with a confirmation of intent to process the command.

Chapter 8. Clustered system diagnostic and service-aid commands

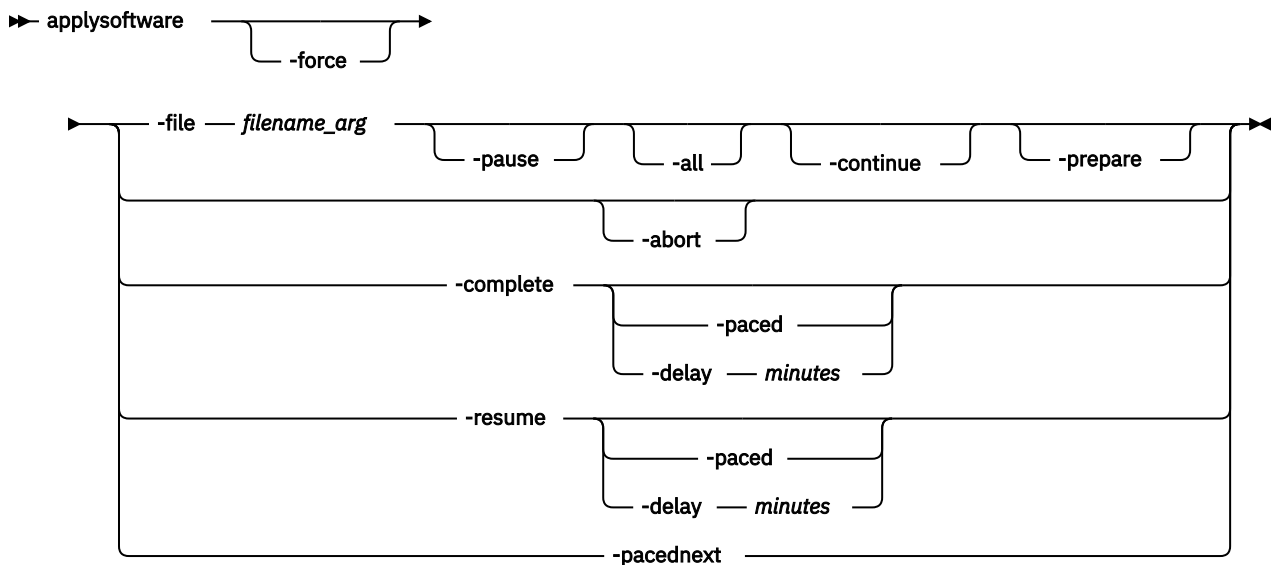

Use the clustered system diagnostic and service-aid commands to diagnose and find system problems.

The system enables you to perform service activity, such as problem determination and repair activities, with a limited set of command-line tools. When you are logged in under the administrator role, all command-line activities are permitted. When you are logged in under the service role, only those commands that are required for service are enabled. The system diagnostic and service-aid commands apply under the service role.

applysoftware

Use the **applysoftware** command to update the system to a new level of code.

Syntax

Parameters

-force

(Optional) Specifies that the update or abort must proceed even if there is a lack of redundancy in the system. Disabling redundancy checking might cause loss of data, or loss of access to data. Use the **force** parameter with the **abort** parameter if one or more nodes are offline.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

-file *filename_arg*

(Required) Specifies the file name of the installation update package. Copy the update package onto the configuration node before you run the **applysoftware** command.

Note: The **file** parameter cannot be used with the **abort** parameter.

-pause

(Optional) Specifies that the concurrent upgrade of a node is paused at the halfway point. This parameter must be specified with **-file**.

-all

(Optional) Specifies that the concurrent upgrade of a node is paused before the node is offline for an upgrade. This parameter must be specified with **-file**.

-continue

(Optional) Specifies that the concurrent upgrade continue.

-prepare

(Optional) Prepares the system for a manual code level update.

Note: You can:

- Use the **prepare** parameter with the **file** parameter
- Not use the **prepare** parameter with the **abort** parameter
- Not use the **force** parameter with the **prepare** parameter to go to prepared status

-abort

(Required for stopping an update) Specifies that a stalled or prepared update is stopped, returning the system to the original code level.

Note: The **abort** parameter can be used with the **force** parameter, but not the **file** or **prepare** parameters.

The **abort** parameter can also be used when the **lsupdate** command reports a status of:

- prepare_failed
- prepared (if all nodes are online)

-complete

(Required for completing an update) Specifies that the update completion process is started. Specify **-paced** for the update completion process to be paced. (This process is either automatic or paced.)

-resume

(Required for resuming an update) Resumes a stalled automatic update, update cancel, or update completion process by retrying the step that stalled. Specify **-paced** for the update process to be paced.

-paced

(Optional) Specifies that the update completion is paced. The system does not automatically take any nodes offline - you must specify **-pacednext** to indicate that the next node of the paced update is updated. Specify **-resume** for the update process to be resumed.

-pacednext

(Required if **-paced** is specified and you want the next node to be updated) Specifies that the next node that is part of a paced update be updated.

-delay minutes

(Optional) Specifies that customers can overwrite the default 30-minute delay at the half way point of a CCU.

Description

This command starts the update process of the system to a new level of code. The **applysoftware** command applies a level of code to the node as a service action (Paced update) to update the specific node, or as an automatic update process that update all of the nodes on a system.

The **applysoftware** command cannot be used in service state, which means the system must be running in order for the command to be used and be successful. This command is synchronous and therefore reports success or failure.

The code package as specified by the file name must first be copied onto the current configuration node in the /home/admin/update directory; use the PuTTY secure copy (scp) application to copy the file.

If the **applysoftware** command is successful, the **lsupdate** command reports the status is prepared. If the **applysoftware** command fails, the **lsupdate** command reports the status is inactive.

If specified, the **prepare** parameter must succeed in order to successfully update. It is recommended to use the same package for the prepare as the actual update. The **prepare** parameter can be canceled by using the abort parameter (even after the system is prepared) as long as the **lsupdate** command reports the status as prepared.

Important: The **prepare** parameter might time out. If a time-out occurs, the **prepare** parameter causes an asynchronous condition, and the **lsupdate** command reports the prepare status as preparing. If this happens, wait until **lsupdate** reports the update as prepared before you proceed with the manual update process.

The command completes as soon as the update process is successful. The command fails and the update package is deleted if:

- The specified package fails an integrity check due to corruption.
- Any node in the system has a hardware type that is not supported by the new code.
- The new code level does not support updates from the currently installed code.
- The code level of a remote system is incompatible with the new code.
- There are volumes-dependent on the status of a node.

Note: The **force** parameter can be used to override these scenarios if you are prepared to lose access to data during the update. Before proceeding, use the **lsdependentvdisks** command with the **node** parameter to list the node-dependent volumes at the time the command is run. If the command returns an error, move the quorum disks to MDisk that are accessible through all nodes. Rerun the command until no errors are returned.

The actual update completes asynchronously.

An invocation example

```
applysoftware -file filename_arg
```

The resulting output:

No feedback

caterlog (Deprecated)

The **caterlog** command has been deprecated. Use the **lseventlog** command instead.

caterlogbyseqnum (Deprecated)

The **caterlogbyseqnum** command has been deprecated. Use the **lseventlog** command instead.

cherrstate (Deprecated)

The **cherrstate** command has been deprecated. Use the **cheventlog** command instead.

chdnserver

Use the **chdnserver** command to change a Domain Name System (DNS) server Internet Protocol (IP) address or name on a system.

Syntax

Note: This command is not supported by 840 AE1.

Parameters

-ip ip_address

(Optional) Specifies the DNS server IP address. The value must be in standard IPv4 or IPv6 format.

-name DNS_name

(Optional) Specifies a unique name for the system DNS server that is being changed.

dns_name | dns_id

(Required) Specifies DNS unique name or ID associated with the DNS server that is being changed.

Description

This command changes DNS server parameters (such as an IP address or name).

An invocation example

```
chdnserver -ip 192.168.48.220 1
```

The resulting output:

```
No feedback
```

An invocation example

```
chdnserver -name dns1 1
```

The resulting output:

```
No feedback
```

cheventlog

Use the **cheventlog** command to modify events in the event log.

Syntax

► cheventlog — — -fix — *sequence_number* ➤

Parameters

-fix *sequence_number*

(Required) Mark an unfixed event as fixed.

Description

Important: You must specify the **-fix** parameter.

An invocation example to mark an event fixed

```
cheventlog -fix 120
```

The resulting output:

```
No feedback
```

chsyslogserver

Use the **chsyslogserver** command to modify the parameters of an existing syslog server.

Syntax

► chsyslogserver — — -name — *server_name* — — -ip — *ip_address_or_dns_name* — —

— — -facility — *facility* — — -error — — on — — off — —

— — -warning — — on — — off — — -info — — on — — off — —

— — -audit — — off — — on — — -login — — off — — on — —

— — -protocol — — udp — — tcp — — -port — *port_number* — — -cadf — — on — — off — —

— — *syslog_server_name* — — *syslog_server_id* — — ➤

Parameters

-name *server_name*

(Optional) Specifies a name to assign to the syslog server. The name must be unique. When specifying a server name, `syslog` is a reserved word.

-ip *ip_address_or_dns_name*

(Optional) Specifies an IP address or domain name to assign to the syslog server. This must be a valid IPv4 or IPv6 address or alphanumeric.

-facility *facility*

(Optional) Specifies a facility number to identify the origin of the message to the receiving server. Servers configured with facility values of 0 - 3 receive syslog messages in concise format. Servers configured with facility values of 4 - 7 receive syslog messages in fully-expanded format. This parameter is mutually-exclusive with **-cadf**.

-error on | off

(Optional) Specifies whether the server receives error notifications. Set to `on`, error notifications are sent to the syslog server. Set to `off`, error notifications are not sent to the syslog server.

-warning on | off

(Optional) Specifies whether the server receives warning notifications. Set to `on`, warning notifications are sent to the syslog server. Set to `off`, warning notifications are not sent to the syslog server.

-info on | off

(Optional) Specifies whether the server receives information notifications. Set to `on`, information notifications are sent to the syslog server. Set to `off`, information notifications are not sent to the syslog server.

-audit on | off

(Optional) Specifies whether the server receives CLI audit logs. The default value is `off`. These notifications are always sent as facility level 3 messages.

-login on | off

(Optional) Specifies whether the server receives authentication logs. The default value is `off`. These notifications are always sent as facility level 3 messages.

-protocol *tcp | udp*

(Optional) Specifies the communication protocol that is used by this server. The default value is `udp`.

-port *port_number*

(Optional) Specifies the communication port that is used by this server. You cannot use this parameter unless **-protocol** is specified. This number must be in the range of 1 - 65535. The default value is 514 for `udp` and 6514 for `tcp`.

-cadf on | off

(Optional) Specifies that Cloud Auditing Data Federation (CADF) data reporting be turned on or `off`. Any syslog notifications sent to the server are formatted to the CADF standard. This parameter is mutually-exclusive with **-facility**.

syslog_server_name* / *syslog_server_id

(Required) Specifies the name or ID of the server to be modified.

Description

Use this command to change the settings of an existing syslog server. You must specify either the current name of the server or the ID returned at creation time. Use the **lssyslogserver** command to obtain this ID.

-login messages are sent to the `authpriv` facility on the remote syslog server and **-audit** messages are sent to `facility.notice` level (where `facility` is what's being selected when you create the syslog server and level is always `notice`).

If you disable CADF notifications for a syslog server that has CADF notification enabled, the facility value must be set to 0.

An invocation example

```
chsyslogserver -facility 5 2
```

The resulting output:

```
No feedback
```

An invocation example

```
chsyslogserver -cadf on 0
```

The resulting output:

```
No feedback
```

Other invocation examples

```
chsyslogserver -name syslog1 -ip 192.168.0.1 -facility 7 -protocol udp -audit off 1
chsyslogserver -name newname -ip 192.168.0.2 -facility 7 -protocol tcp syslog2
chsyslogserver -name syslog3 -ip 192.168.0.3 -cadf on -login on -protocol udp -port 514 2
chsyslogserver -name syslog4 -ip 192.168.0.4 -audit off -login off -protocol tcp -port 6514
syslog1
```

clearerrlog

Use the **clearerrlog** command to clear all entries from the event log including status events and any unfixed errors.

Syntax

```
➤ clearerrlog 
```

Parameters

-force

(Optional) Specifies that the **clearerrlog** command be processed without confirmation requests. If the **-force** parameter is not supplied, you are prompted to confirm that you want to clear the log.

Description

This command clears all entries from the event log. The entries are cleared even if there are unfixed events in the log. It also clears any status events that are in the log.

Attention: This command is destructive. Use it only when you have either rebuilt the clustered system or have fixed a major problem that has caused entries in the event log that you do not want to manually fix.

An invocation example

```
clearerrlog -force
```

The resulting output:

```
No feedback
```

cpfabricdumps (Discontinued)

The **cpfabricdumps** command is discontinued. Use the **cpdumps** command instead.

dumpperlog

Use the **dumpperlog** command to dump the contents of the event log to a text file.

Syntax

➤ **dumpperlog** 

Parameters

-prefix filename_prefix

(Optional) A file name is created from the prefix and a time stamp, and has the following format:

prefix_NNNNNN_YYMMDD_HHMMSS

where *NNNNNN* is the node front panel name.

Note: If the **-prefix** parameter is not supplied, the dump is directed to a file with a system-defined prefix of **errlog**.

Description

When run with no parameters, this command dumps the system event log to a file using a system-supplied prefix of **errlog**, which includes the node ID and time stamp. When a file name prefix is provided, the same operation is performed but the details are stored in the dumps directory within a file with a name that starts with the specified prefix.

A maximum of ten event-log dump files are kept on the system. When the 11th dump is made, the oldest existing dump file is overwritten.

Event log dump files are written to **/dumps/elog**s. The contents of this directory can be viewed using the **lsdumps** command.

Files are not deleted from other nodes until you issue the **cleardumps** command.

Note: The DMP family is printed at the end of all events in the event log.

An invocation example

```
dumpperlog -prefix testerrorlog
```

The resulting output:

```
No feedback
```

finderr

Use the **finderr** command to analyze the event log for the highest severity unfixed event.

Syntax

➤ **finderr** ➤

Parameters

None

Description

The command scans the event log for any unfixed events. Given a priority ordering within the code, the highest priority unfixed event is returned to standard output.

You can use this command to determine the order in which to fix the logged event.

An invocation example

```
finderr
```

The resulting output

```
Highest priority unfixed event code is [1010]
```

setevent (Discontinued)

Attention: The **setevent** command is discontinued. SNMP notification can be configured using the following commands: **svctask mksnmpserver**, **svctask chsnmpserver**, **svctask rnsnmpserver**, and **svcinfo lssnmpserver**.

lscimomdumps (Deprecated)

The **lscimomdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lscopystatus

Use the **lscopystatus** command to determine whether any file copies are currently in progress.

Syntax

► lscopystatus 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim *delimiter*

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This command displays an indicator that shows if a file copy is in progress. Only one file can be copied in the clustered system at a time.

An invocation example

```
lscopystatus
```

The resulting output:

```
status  
active
```

lsdumps

Use the **lsdumps** command to display a list of files in a particular dumps directory on one of the nodes in the system.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, then the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-prefix directory_name

(Optional) Specifies the name of the directory to list files for. The default is the /dumps directory. Valid directory names:

- /dumps
- /dumps/audit
- /dumps/cimom
- /dumps/cloud
- /dumps/easytier
- /dumps/elogs
- /dumps/feature
- /dumps/iostats
- /dumps/iotrace
- /dumps/mdisk
- /home/admin/update

- /dumps/drive
- /dumps/enclosure

node_name / node_id

(Optional) Specifies the node ID or name to list the available dumps for. If you do not specify a node, the available dumps on the configuration node are listed.

Description

This command displays a list of files that are detected by a node. You can specify the name of the directory to list files for, and the node ID or name. If you do not specify a directory, the /dumps directory is used.

The files are listed in order of time that is created, with the oldest files listed first.

Use the **lsdumps** command with the optional **prefix** parameter to specify a directory. If you do not specify a directory, /dumps is used as the default. Use the optional *node_id_or_name* parameter to specify the node to list the available dumps. If you do not specify a node, the available dumps on the configuration node are listed.

An invocation example to list the files in /dumps on the configuration node

```
lsdumps
```

The resulting output:

```
id  filename
0   svc.config.cron.bak_node1
1   svc.config.backup.xml_node1
2   recover.110584.100116.035201
3   dump.110584.100118.051550
4   ethernet.aaabbbX-1.trc
```

An invocation example to list the files in /dumps/easytier on the configuration node

```
lsdumps -prefix /dumps/easytier/ node_1
```

The resulting output:

```
id filename
0   dpa_heat.78RE5LV-1.150705.074636.data
1   dpa_log_78RE5LV-1_20150707062320_00000000.xml.gz
```

lsdnsserver

Use the **lsdnsserver** command to list information for any Domain Name System (DNS) servers in the system.

Syntax

Note: This command is not supported by 840 AE1.

Parameters

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

dns_name / dns_id

(Optional) Specifies the DNS server name or ID for which to display details. The value for the ID must be a number and the value for the name must be an alphanumeric string.

Description

This command lists information for any DNS servers in the system.

This value provides the attribute values that can be displayed as output view data.

Table 67. <i>lsdnsserver</i> output	
Attribute	Description
id	Indicates the DNS server ID. The value must be a number.
name	Indicates the DNS server name. The value must be an alphanumeric string.
type	Indicates the DNS server Internet Protocol (IP) address type. The value must be a standard IPv4 or IPv6 address.
IP_address	Indicates the IP address of the DNS server. The value must be a standard IPv4 or IPv6 address.

A concise invocation example

```
lsdnsserver
```

The resulting output:

id	name	type	IP_address
0	DNS1	ipv6	
2801:0000:0000:0000:0000:0000:0000:0100			
1	DNS2	ipv4	192.168.44.34

A detailed invocation example

```
lsdnsserver 1
```

The resulting output:

```
id 1
name DNS2
type ipv4
IP_address 192.168.44.34
```

lserrlogbyfcconsistgrp (Deprecated)

The **lserrlogbyfcconsistgrp** command has been deprecated. Use the **lseventlog** command instead.

lserrlogbyfcmap (Deprecated)

The **lserrlogbyfcmap** command has been deprecated. Use the **lseventlog** command instead.

lserrlogbyhost (Deprecated)

The **lserrlogbyhost** command has been deprecated. Use the **lseventlog** command instead.

lserrlogbyiogrp (Deprecated)

The **lserrlogbyiogrp** command has been deprecated. Use the **lseventlog** command instead.

lserrlogbymdisk (Deprecated)

The **lserrorlogbymdisk** command has been deprecated. Use the **lseventlog** command instead.

lserrlogbymdiskgrp (Deprecated)

The **lserrlogbymdiskgrp** command has been deprecated. Use the **lseventlog** command instead.

lserrlogbynode (Deprecated)

The **lserrlogbynode** command has been deprecated. Use the **lseventlog** command instead.

lserrlogbyrconsistgrp (Deprecated)

Attention: The **lserrlogbyrconsistgrp** command has been deprecated. Use the **lseventlog** command instead.

lserrlogbyrrelationship (Deprecated)

The **lserrlogbyrrelationship** command has been deprecated. Use the **lseventlog** command instead.

lserrlogbyvdisk (Deprecated)

The **svcinfo lserrlogbyvdisk** command has been deprecated. Use the **svcinfo lseventlog** command instead.

lserrlogdumps (Deprecated)

The **lserrlogdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

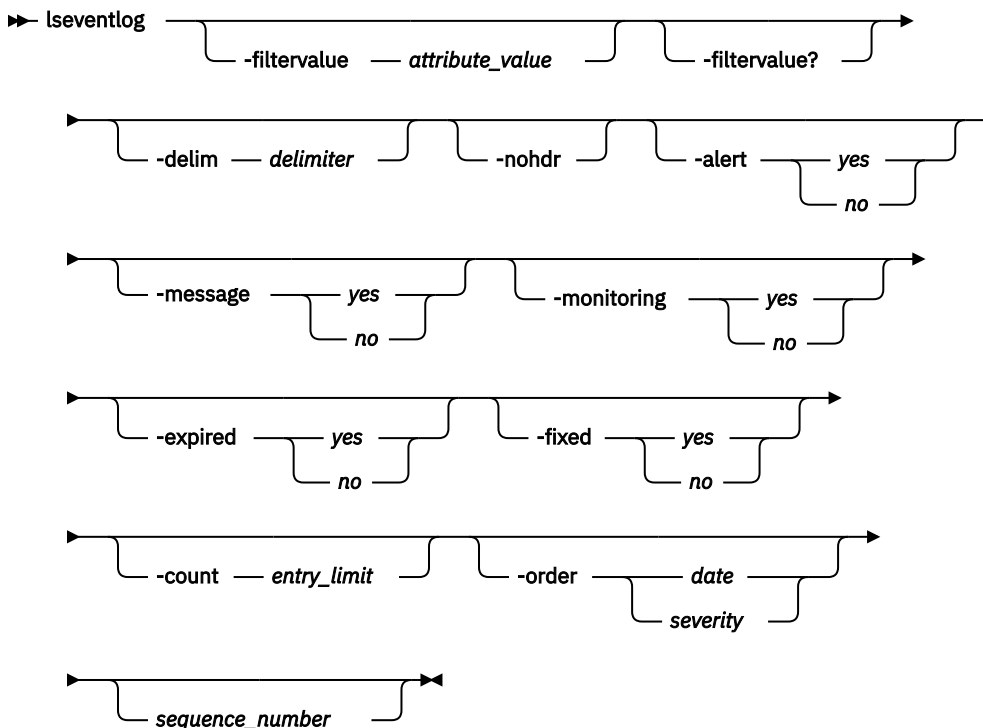

lsfeaturedumps (Deprecated)

The **lsfeaturedumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lseventlog

Use the **lseventlog** command to display a concise view of the system event log, or a detailed view of one entry from the log.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are returned. If a capacity is specified, the units must also be included.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards on the CLI:

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, you must enclose the filter entry within double quotation marks (" "), as follows:

```
lseventlog -filtervalue "object_name=ob*"
```

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-alert yes / no

(Optional) Includes (or excludes) events with *alert* status.

-message yes / no

(Optional) Includes events with *message* status.

-monitoring yes / no

(Optional) Includes events with *monitoring* status.

-expired yes / no

(Optional) Includes (or excludes) events with *expired* status.

-fixed yes / no

(Optional) Includes (or excludes) events with *fixed* status.

-count entry_limit

(Optional) Indicates the maximum number of events to display.

-order date / severity

(Optional) Indicates what order the events must be in. Ordering by *date* displays the oldest events first. Ordering by *severity* displays the events with the highest severity first. If multiple events have the same severity, then they are ordered by date, with the oldest event displayed first.

The following list shows the order of severity, starting with the most severe:

1. Unfixed alerts (sorted by error code; the lowest error code has the highest severity)
2. Unfixed messages
3. Monitoring events (sorted by error code; the lowest error code has the highest severity)
4. Expired events
5. Fixed alerts and messages

-filtervalue?

(Optional) Displays a list of valid filter attributes for the **-filtervalue** *attribute=value* parameter:

- copy_id
- error_code
- event_count
- event_id
- fixed
- last_timestamp
- object_id
- object_name
- object_type
- reporting_node_id
- reporting_node_name
- root_sequence_number
- sequence_number
- status

sequence_number

(Optional) Indicates whether the command must display a full view of the event.

Description

This command displays a concise view of the system event log, or a detailed view of one entry from the log. You can sort the events and entries by severity or age.

The default values for included events are:

- alert=yes
- expired=no

- fixed=no
- message=yes
- monitoring=no

This table provides the attribute values that can be displayed as output view data.

<i>Table 68. lseventlog output</i>		
Attribute	Description	Value
machine_type	Indicates the node machine type and model number.	The value is an alphanumeric string up to 7 characters long.
serial number	Indicates the node serial number.	The value is an alphanumeric string up to 7 characters long.
sequence_number	Indicates the sequence number of the event.	The value is numeric from 0 to 8000000.
first_timestamp	Indicates when the event was added to the log.	The value is in the format YYMMDDHHMMSS.
first_timestamp_epoch	Indicates when the event was added to the log (in seconds) after the epoch occurs.	The value is a numeric 32-bit value.
last_timestamp	Indicates when the event was most recently updated.	The value is in the format YYMMDDHHMMSS.
last_timestamp_epoch	Indicates the most recent update (in seconds) after an epoch for an event.	The value is a numeric 32-bit value.
fixed_timestamp	Indicates the time stamp when event is fixed.	The value is in the format YYMMDDHHMMSS.
fixed_timestamp_epoch	Indicates the time stamp (in seconds) when an event is fixed after an epoch occurs.	The value is a numeric string.
fru	Indicates the field-replaceable unit (FRU) for error or event; this field contains probable FRUs (separated by commas).	The value is an ASCII string up to 255 characters long.

Table 68. **lseventlog** output (continued)

Attribute	Description	Value
object_type	Indicates the type of the object the event is logged against.	<p>The values are:</p> <ul style="list-style-type: none"> • mdisk • mdiskgrp • volume (or volume copy) • node • host • io_grp (iogroup in dumperrlog) • fc_consist_grp (fcgrp in dumperrlog) • rc_consist_grp (rcgrp in dumperrlog) • fc_map (fcmap in dumperrlog; <i>flash</i> in caterrrlog) • rc_relationship (rcmap in dumperrlog; <i>remote</i> in caterrrlog) • cluster • controller (device in caterrrlog and dumperrlog) • quorum • migrate • email_server (<i>emailserver</i> in caterrrlog and dumperrlog) • enclosure • drive
object_id	Indicates the ID of the object the event is logged against.	<p>The value is a numeric 64-bit value. It is displayed in decimal for all object types other than clustered systems.</p> <p>For a clustered system, this value is hexadecimal but is blank for events with cluster object types.</p>
object_name	Indicates the name of the object the event is logged against.	This value is the object name format and is blank if the object was deleted or does not have a name.
copy_id	Indicates the volume copy ID the event is logged against.	The value is a numeric value 0 to 1; it is blank if not a vdiskcopy event.

Table 68. **lseventlog** output (continued)

Attribute	Description	Value
reporting_node_id	Indicates the ID of the node that reported the event.	The value is a numeric 64-bit value that is blank if the event is reported by the clustered system.
reporting_node_name	Indicates the name of the node that reported the event.	This value is the object name format and is blank if node is deleted or event is reported by the clustered system.
root_sequence_number	Indicates the sequence number of the root or causal event Important: If the event is directly caused by another event, the sequence_number of the related event is shown here.	The value is a numeric value from 1 to 8000000; blank if there is no root or if the event is not directly caused by another event.
event_count	Indicates the number of reported events that are combined into this event	The value is a numeric 32-bit value.
status	Indicates the event category.	The values are: <ul style="list-style-type: none"> • alert • message • monitoring • expired
fixed	Indicates whether the event was marked fixed (for an alert) or read (for a message).	The values are: <ul style="list-style-type: none"> • yes • no (for events that cannot be fixed, or are not fixed)
auto_fixed	Indicates whether event is marked fixed by the code.	The values are: <ul style="list-style-type: none"> • yes • no (for events that cannot be fixed, or are not fixed)
notification_type	Indicates the type of event notification.	The values are: <ul style="list-style-type: none"> • error • warning • informational • none
event_id	Indicates the event ID.	The value is a 6-digit numeric value.
event_id_text	Indicates the description that is associated with the event ID.	The value is a text value with a maximum of 200 bytes. This appears in CLI requested language.

Table 68. **lseventlog** output (continued)

Attribute	Description	Value
error_code	Indicates the error code that is associated with this event.	The value is a 4-digit numeric value but is blank if there is no error code.
error_code_text	Indicates the description that is associated with the error code.	The value is a text value with a maximum of 200 bytes that is blank if there is no error code. This value appears in the language that is requested by the CLI.
description	Indicates the description that is associated with the event. If the event has an error code, this value is the same as the error_code_text field; otherwise, it is the same as the event_id_text field	Text (maximum of 200 bytes).
sense1	Indicates the sixteen bytes of hex-encoded sense data; least significant byte is on the left.	The value is 16 2-character hexadecimal numbers that are separated by spaces.

Invocation examples

This example shows events in January 2010:

```
lseventlog -filtervalue 'last_timestamp>=100101000000:last_timestamp<100201000000'
```

This example shows all unfixed 1065 errors, in order of occurrence:

```
lseventlog -filtervalue error_code=1065:fixed=no
```

This example lists the most critical event:

```
lseventlog -order severity -count 1
```

This example shows the concise view:

```
lseventlog
sequence_number:last_timestamp:object_type:object_id:object_name:copy_id:
status:fixed:event_id:error_code:description
400:100106132413:vdisk:2:my_vdisk:1:alert:no:060001:1865:
Space Efficient Virtual Disk Copy offline due to insufficient space
401:100106140000:cluster::ldcluster-2::message:no:981001:
:Cluster Fabric View updated by fabric discovery
```

This example shows the full view:

```
lseventlog 120

```

lssyslogserver

Use the **lssyslogserver** command to return a concise list or a detailed view of syslog servers that are configured on the clustered system.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum possible width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a one-

byte character. If you enter `-delim :` on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

syslog_server_name / syslog_server_id

(Optional) Specifies the name or ID of an existing syslog server. When you use this parameter, a detailed view of the specified syslog server is returned. If you do not specify a syslog server name or ID, then a concise view of all syslog servers is displayed.

Description

Use this command to display a concise list or a detailed view of syslog servers that are configured on the clustered system.

This table provides the attribute values that can be displayed as output view data.

<i>Table 69. lssyslogserver output</i>	
Attribute	Description
id	Indicates the syslog server ID. The value must be a number.
name	Indicates the syslog server name. The value must be an alphanumeric string.
IP_address	Indicates the syslog server Internet Protocol (IP) address. The value must be a valid IP address.
facility	Indicates the syslog server facility value. The value must be a number 0 - 7 but is blank for a CADF notification-enabled server.
error	Indicates whether error messages are on. The values are on or off.
warning	Indicates whether warning messages are on. The values are on or off.
info	Indicates whether informational messages are on. The values are on or off.
cadf	Indicates whether CADF data reporting is enabled or not for the syslog server. The values are on or off.
audit	Indicates whether this server receives CLI audit logs. The values are on or off (default).
login	Indicates whether this server receives authentication logs. The values are on or off (default).
protocol	Indicates the communication protocol that is used by this server (or blank for default). The values are tcp or udp (default).
port	Indicates the communication port that is used by this server (or blank for default). The value is an integer in the range of 1 - 65535. A value of 514 indicates UDP protocol and a value of 6514 indicates TCP protocol.

A concise invocation example

```
lssyslogserver -delim :
```

The concise resulting output:

```
id:name:IP_address:facility:error:warning:info:cadf:audit:login:protocol:port
0:syslog0:192.135.60.4::on:on:on:on:on:udp:514
1:newserver:192.136.70.7:4:on:off:off:on:on:off:tcp:6514
```

A detailed invocation example

```
lssyslogserver 0
```

The detailed resulting output:

```
id 0
name syslog0
IP_address 192.135.60.4
facility
error on
warning on
info on
cadf on
audit on
login on
protocol udp
port 514
```

lssoftwaredumps (Deprecated)

The **lssoftwaredumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lssoftwareupgradestatus (Deprecated)

The **lssoftwareupgradestatus** command is deprecated. Use the **lsupdate** command instead.

lssystemsupportcenter

Use the **lssystemsupportcenter** command to list details about remote support servers.

Syntax

Parameters

support_center_name / support_center_id

(Optional) Specifies a name or ID for a remote support server in the server index. The value for the ID must be a number (integer) and the value for the name must be an alphanumeric string. This parameter displays a full view of any configured name or ID values.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data is displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a

concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This command lists details about remote support servers.

This command returns a concise or detailed view of the remote support servers defined.

This table provides the attribute values that can be displayed as output view data.

Table 70. <i>lssystemssupportcenter</i> output	
Attribute	Description
id	Indicates the support center or proxy server ID. The value must be a number (integer).
name	Indicates the support center or proxy server name. The value must be an alphanumeric string.
IP_address	Indicates the Internet Protocol Version 4 (IPv4) or Version 6 (IPv6) address for the new support center or proxy server. The value must be a valid IPv4 or IPv6 address.
port	Indicates the port number for the configured support center or the proxy server. The value must be a number (integer).
proxy	Indicates that the target server is a proxy server (and not the support center). The values are yes or no.

An invocation example

```
lssystemssupportcenter
```

The following output is displayed:

```
id name IP_address port proxy
0 proxy1 1.2.3.4 9999 yes
1 supportserver2 1.2.3.5 8888 no
2 test_frontend_server 9.51.88.165 1025 no
```

An invocation example

```
lssystemssupportcenter 2
```

The following output is displayed:

```
id 2
name supportserver2
IP_address 1.2.3.5
port 8888
proxy no
```

An invocation example

```
lssystemssupportcenter -delim :
```

The following output is displayed:

```
id:name:IP_address:port:proxy
0:proxy1:1.2.3.4:9999:yes
1:supportserver2:1.2.3.5:8888:no
2:test_frontend_server:9.51.88.165:1025:no
```

lsupdate

Use the **lsupdate** command to display a system's machine code (code) upgrade status.

Syntax

➔ **lsupdate** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim *delimiter*

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

The **applysoftware** command is used to update the system code. The following are the upgrade status states reported by the **lsupdate** command:

status

Indicates the overall update-related status of the system. The values are:

- success, which indicates that all updating activity is complete.
- system_preparing, which indicates that the system is preparing a manual update.
- system_prepared, which indicates that the system is ready to starting a manual update.
- system_prepare_failed, which indicates that the system could not start a manual update.

Note: Check the event log.

- system_initializing, which indicates that the system is readying nodes for an update.
- system_updating, which indicates that the nodes are being updated.
- system_updating_pausing, which indicates that the system is pausing before it continues to update the nodes.
- **Note:** If you specify **applysoftware -continue** the status changes to **system_updating**.
- system_committing, which indicates that all nodes are updated and the system is readying the new code.
- system_stalled, which indicates that an update is stalled because of unexpected node problems.
- system_stalled_non_redundant, which indicates that an update is stalled because of dependent volumes.
- system_restoring, which indicates that a stalled update is canceled by the user.

Note: The previous code version is being restored.

- system_restoring_pausing, which indicates that the system is pausing before it continues to restore the nodes.

Note: If you specify `applysoftware -continue` the status changes to `system_updating_restoring`.

- `system_restoring_stalled_non_redundant`, which indicates that an update is canceled and then stalled because of dependent volumes.
- `system_manual_update`, which indicates that a manual update is in progress.
- `system_completion_required`, which indicates that all nodes are updated and management functions are available, but further system changes are necessary to complete the update.

Note: Check the event log.

- `system_completing`, which indicates that an automatic update completion is in progress.
- `system_completing_pausing`, which indicates that automatic update completion is paused.
- `system_completing_paced`, which indicates that a paced update completion is in progress.
- `system_completing_stalled`, which indicates that an automatic update completion stalled because of an unexpected problem.
- `enclosures`, which indicates that enclosure firmware is being updated.
- `enclosures_stalled`, which indicates that an enclosure firmware update stalled because of an unexpected problem or the enclosure has a lack of redundancy.
- `enclosures_restoring`, which indicates a stalled update has been canceled by the user. The previous code version is being restored to the enclosure canisters.
- `drives`, which indicates that drive firmware is being updated.

event_sequence_number

Indicates an event that describes any current problem with the code update. The value must be a numeric string in decimal format (or blank).

progress

Indicates the completion percentage of the current update activity in terms of number of objects updated (rather than time elapsed). The value must be a numeric string (decimal) in the range 0 - 100.

estimated_completion_time

Indicates estimated completion time of current update activity. It is valid only if the current update activity is automatic and is not stalled. The value must be in the format `YYMMDDHHMMSS` (or blank).

suggested_action

Indicates the actions that help the update progress. The value must be:

- `complete`, which indicates the system update is complete and update completion must be issued. Nodes are online.
- `continue`, which indicates that the concurrent upgrade is paused and you must `applysoftware -continue` to continue the concurrent upgrade.
- `fix`, which indicates that an update cannot continue because of a problem. Check the event log, specifically the **event_sequence_number** output. Nodes are offline.
- `manual`, which indicates that a manual update is in progress.
- `pacednext`, which indicates that the paced update is in progress and the next node must be scheduled for updating. Nodes are online.
- `resume_cancel`, which indicates that the update is stalled but can be resumed or canceled. Nodes are online.
- `resume`, which indicates that the update completion is stalled but can be resumed. Nodes are online.
- `start`, which indicates that the system is ready for a new update to start. No update is in progress or prepared and all nodes are online.
- `wait`, which indicates that the system is busy (no action is required) because an update is in progress.

system_new_code_level

Indicates that a new level of code is being updated. The value must be the build version (or blank if not updating or restoring the system).

system_forced

Indicates any current node-related activity in forced mode (ignoring dependent volumes). The values are yes or no.

system_next_node_status

Indicates the status of the next node in the current node-related update activity. The values are:

- none, which indicates that there is no node to update.
- paused, which indicates that the current node is paused during a concurrent upgrade, and you must applysoftware -continue to continue the concurrent upgrade.
- waiting, which indicates that the node is ready for updating and that the system is waiting (typically for multipathing failover).
- ready, which indicates that the node is ready for updating, and the update activity is paced. You must start the update manually.
- updating, which indicates that the node is updating.
- stalled, which indicates that the node is going to be updated next, but the update is stalled.

system_next_node_time

Indicates the time that the next node update will start. It is valid only if the **system_next_node_status** is waiting. The value must be in the format YYMMDDHHMMSS x (or blank).

system_next_node_id

Indicates the ID of the next node in the current node-related update. The value must be a numeric string (or blank).

system_next_node_name

Indicates the name of the next node in the current node-related update. The value must be an alphanumeric string (or blank).

An invocation example of an update

```
lsupdate
```

The resulting output:

```
status system_updating
event_sequence_number
progress 50
estimated_completion_time 140522093020
suggested_action wait
system_new_code_level 7.4.0.1 (build 99.2.141022001)
system_forced no
system_next_node_status updating
system_next_node_time
system_next_node_id 2
system_next_node_name node2
```

An invocation example of a paced update

```
lsupdate
```

The resulting output:

```
status system_completing_paced
event_sequence_number
progress 75
estimated_completion_time
suggested_action pacednext
system_new_code_level
system_forced no
system_next_node_status ready
```

```
system_next_node_time
system_next_node_id 4
system_next_node_name node4
```

mkdnsserver

Use the **mkdnsserver** command to configure a new Domain Name System (DNS) server for a system.

Syntax

Note: This command is not supported by 840 AE1.

```
➤ mkdnsserver  — -ip — ip_address  — -name — DNS_name  ➤
```

Parameters

-ip *ip_address*

(Required) Specifies the DNS server Internet Protocol (IP) address. The value must be in standard IPv4 or IPv6 format. Depending on the format you specify the system will validate the format to make sure it is correct.

-name *DNS_name*

(Optional) Specifies a unique name for the system DNS server being created. If a DNS server name is not specified, a unique name is generated and then assigned to the DNS server.

Description

This command configures a new DNS server for a system.

For IBM Spectrum Virtualize for Public Cloud on Amazon Web Services (AWS), one AWS DNS server is set up during installation. You are limited to adding two (instead of three) DNS servers by using this command.

Use the **-ip** parameter to specify the DNS server IP address. You can enter any valid IPv4 or IPv6 address. The system validates the format of specified IP address to make sure that it is correct.

An invocation example

```
mkdnsserver -ip 192.168.44.34
```

The resulting output:

```
DNS Server id [0] successfully created
```

An invocation example

```
mkdnsserver -ip 2801:0000:0000:0000:0000:0000:0000:0100
```

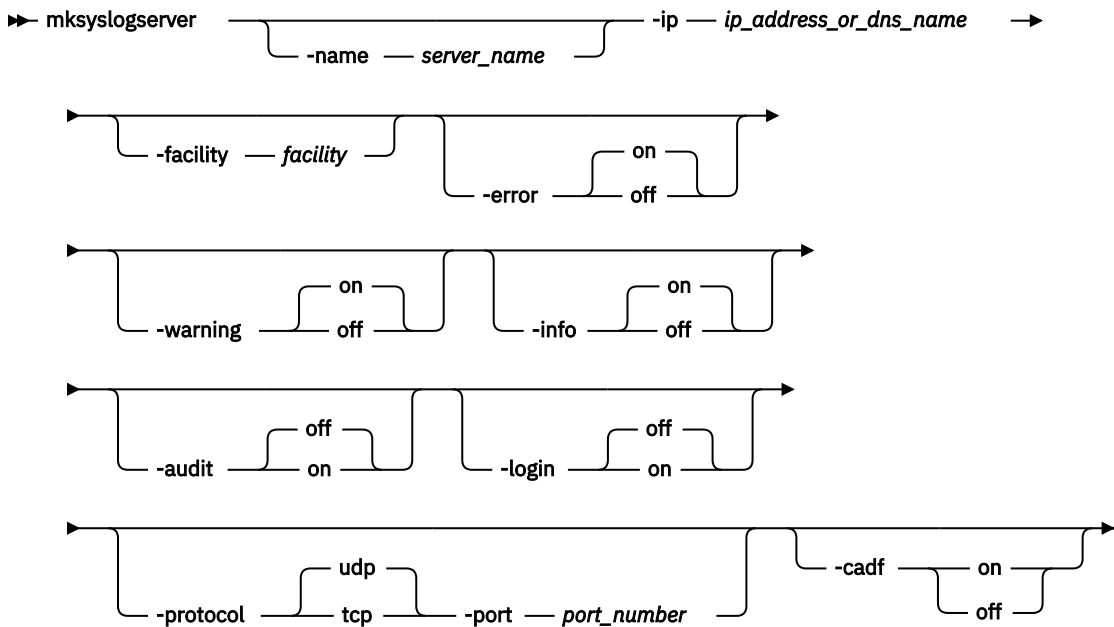

The resulting output:

```
DNS Server id [1] successfully created
```

mksyslogserver

Use the **mksyslogserver** command to create a syslog server to receive notifications.

Syntax

Parameters

-name *server_name*

(Optional) Specifies a unique name to assign to the syslog server. If a name is not specified, then a system default of *syslogn* is applied, where *n* is the ID of the server. When specifying a server name, *syslog* is a reserved word.

-ip *ip_address_or_dns_name*

(Required) Specifies the Internet Protocol (IP) address or domain name of the syslog server. This must be a valid Internet Protocol Version 4 (IPv4) or Internet Protocol Version 6 (IPv6) address or alphanumeric.

-facility *facility*

(Optional) Specifies the facility number used in syslog messages. This number identifies the origin of the message to the receiving server. Servers configured with facility values of 0 - 3 receive syslog messages in concise format. Servers configured with facility values of 4 - 7 receive syslog messages in fully-expanded format. The default value is 0.

-error *on* | *off*

(Optional) Specifies whether the server receives error notifications. Set to *on*, error notifications are sent to the syslog server. Set to *off*, error notifications are not sent to the syslog server. The default value is *on*.

-warning *on* | *off*

(Optional) Specifies whether the server receives warning notifications. Set to *on*, warning notifications are sent to the syslog server. Set to *off*, warning notifications are not sent to the syslog server. The default value is *on*.

-info *on* | *off*

(Optional) Specifies whether the server receives information notifications. Set to *on*, information notifications are sent to the syslog server. Set to *off*, information notifications are not sent to the syslog server. The default value is *on*.

-audit *on* | *off*

(Optional) Specifies whether the server receives CLI audit logs. The default value is *off*.

-login on | off

(Optional) Specifies whether the server receives authentication logs. The default value is off.

-protocol tcp | udp

(Optional) Specifies the communication protocol that is used by this server. The default value is udp.

-port port_number

(Optional) Specifies the communication port that is used by this server. You cannot use this parameter unless **-protocol** is specified. This number must be in the range of 1 - 65535. The default value is 514 for udp and 6514 for tcp.

-cadf on | off

(Optional) Specifies that Cloud Auditing Data Federation (CADF) data reporting be turned on or off. Any syslog notifications sent to the server are formatted to the CADF standard. This parameter is mutually-exclusive with **-facility**.

Description

This command creates a syslog server to receive notifications. The syslog protocol is a client-server standard for forwarding log messages from a sender to a receiver on an IP network. Syslog can be used to integrate log messages from different types of systems into a central repository.

-login messages are sent to the authpriv facility on the remote syslog server and **-audit** messages are sent to facility.notice level (where facility is what's being selected when you create the syslog server and level is always notice).

SAN Volume Controller supports a maximum of six syslog servers.

An invocation example

```
mksyslogserver -ip 1.2.3.4
```

The resulting output:

```
Syslog Server id [2] successfully created
```

An invocation example

```
mksyslogserver -ip 9.193.231.37 -error on -warning on -info off -cadf on
```

The resulting output:

```
Syslog Server id [2] successfully created
```

Invocation examples

```
mksyslogserver -name syslog1 -ip 192.168.0.1 -audit off
mksyslogserver -name syslog2 -ip 192.168.0.2 -audit on -login off
mksyslogserver -name syslog3 -ip 192.168.0.3 -facility 7 -protocol udp
mksyslogserver -name syslog4 -ip 192.168.0.4 -facility 7 -protocol tcp
mksyslogserver -name syslog5 -ip mysyslog.example.com -cadf on -protocol udp -port 514
mksyslogserver -name syslog6 -ip 192.168.0.6 -cadf on -protocol tcp -port 6514
```

mksystemsupportcenter

Use the **mksystemsupportcenter** command to add a support center or proxy server to your remote support configuration.

Syntax

Parameters

-name *user_name*

(Optional) Specifies the unique name of the support center or proxy to be defined. If a center with that name is defined, the command fails. The value must be an alphanumeric string that:

- Cannot start with the string `default_support_center`
- Cannot start with a hyphen or number
- Cannot begin or end with a space
- Must be 1 - 64 characters long (using numbers, letters, spaces, periods, or an underscore)

Additionally, the names `SupportCenter` and `Proxy` cannot be used as shown. Do not specify these names unless you use all lower-case letters - for example, `supportcenter` or `proxy`.

Note: If you do not specify a name, a system default of `supportservern` is used, where *n* is the object index.

-ip *ipv4_or_ipv6_address*

(Required) Indicates the Internet Protocol Version 4 (IPv4) or Version 6 (IPv6) address for the new support center or proxy server. The value must be a valid IPv4 or IPv6 address.

-port *port*

(Required) Specifies the port number for the new connection. The value must be a number in the range 1 - 65535. The default value is 1025.

-proxy *yes / no*

(Optional) Specifies whether a target server is a proxy server (and not a support center). The values are `yes` or `no`.

Description

This command creates a support center or proxy server to your remote support configuration. The maximum number of proxy servers that you can define is six.

If you configure a proxy server, remote support assistance is available only by using proxy server (which means that no direct connections are tried). If you configure multiple support centers (or proxies), the system cycles through each support center before it enables remote support assistance which means that it tries all support centers at least three times before it ends in `failure` state. Use the set of default support centers that are configured if needed.

Important: Unless your support team recommends it, do not configure any new support centers. However, a proxy server can be configured if required. If you are routing Remote Support connections of a system with all the nodes configured with a service IPv6 address, then you must use a Remote Support proxy server. The proxy server should listen on an IPv6 address. It can additionally listen on IPv4 address. This proxy server IPv6 address needs to be specified on your system using this command (with the `-proxy` parameter).

An invocation example

```
mksystemsupportcenter -name test_frontend_server_1 -ip 9.51.88.165 -port 1025
```

The resulting output:

```
Support Server id [0] successfully created
```

An invocation example

```
mksystemsupportcenter -name customer_proxy_1 -ip 192.168.56.88 -port 9999 -proxy yes
```

The resulting output:

```
Support Server id [1] successfully created
```

An invocation example

```
mksystemsupportcenter -name customer_proxy_2 -ip 192.168.56.101 -port 2222 -proxy yes
```

The resulting output:

```
Support Server id [2] successfully created
```

An invocation example

```
mksystemsupportcenter -ip 2001:0db8:0000:0001:0000:0000:0000:0071 -port 1025 -proxy yes
```

The resulting output:

```
Support Server id [3] successfully created
```

An invocation example

```
mksystemsupportcenter -ip 2001:db8:0:1:0:0:0:71 -port 1025 -proxy yes
```

The resulting output:

```
Support Server id [2] successfully created
```

An invocation example

```
mksystemsupportcenter -ip 2001:db8:0:1::71 -port 1025 -proxy yes
```

The resulting output:

```
Support Server id [2] successfully created
```

rmDNSserver

Use the **rmDNSserver** command to remove a Domain Name System (DNS) server from a system.

Syntax

Note: This command is not supported by 840 AE1.

Parameters

dns_name / *dns_id*

(Required) Specifies the ID or name of the Domain Name System (DNS) server to be removed from the system. The value must be a number for the ID and an alphanumeric string for the name.

Description

This command removes a DNS server from a system.

An invocation example

```
rmdnsserver 1
```

The resulting output:

```
No feedback
```

rmsyslogserver

Use the **rmsyslogserver** command to delete the specified syslog server.

Syntax

Parameters

syslog_server_name / *syslog_server_id*

(Required) Specifies the name or ID of the syslog server to be deleted.

Description

Use this command to delete an existing syslog server. You must specify either the current name of the server or the ID returned at creation time. Use the **lssyslogserver** command to obtain this ID.

An invocation example

```
rmsyslogserver 2
```

The resulting output (if the command is successful):

```
No feedback
```

If the command is not successful, this error message occurs:

```
CMMVC5753E The specified object does not exist or is not a suitable candidate.
```

rmsystemsupportcenter

Use the **rmsystemsupportcenter** command to delete a configured support center or proxy server.

Syntax

Parameters

system_support_name / system_support_id

(Required) Specifies a name or ID for a remote support server in the server index that is to be removed. The value for the ID must be a number (integer) and the value for the name must be an alphanumeric string. The name or ID must correspond to the entry that is displayed when you specify **lssystemsupportcenter**.

Description

This command deletes a configured support center or proxy server.

Note: You cannot remove default support centers that are automatically configured for the system.

An invocation example

```
rmsystemsupportcenter 0
```

The resulting output:

An invocation example

```
rmsystemsupportcenter secret_proxy_server
```

The resulting output:

```
No feedback
```

An invocation example

```
rmsystemsupportcenter special_support_centre
```

The resulting output:

```
No feedback
```

setlocale

Use the **setlocale** command to change the locale setting for the system. It also changes command output to the chosen language.

Syntax

➤ setlocale — -locale — locale_id ➤

Parameters

-locale locale_id

(Required) Specifies the locale ID. The value must be a numeric value depending on the wanted language. The list in the command description shows the possible values.

Description

This command changes the language in which error messages are displayed as output from the command-line interface. Then, all error messages from the command-line tools are generated in the chosen language. This command is run when you request a change of language (locale).

Specify the **setlocale** command to change the locale setting for the system; all interface output is changed to the chosen language. For example, to change the language to Japanese, type the following on the command line:

```
setlocale -locale 3
```

Where 3 is the value for Japanese. The following values are supported:

- 0 US English (default)
- 1 Simplified Chinese
- 2 Traditional Chinese
- 3 Japanese
- 4 French
- 5 German
- 6 Italian
- 7 Spanish
- 8 Korean
- 9 Portuguese (Brazilian)
- 10 Russian

An invocation example (where 3 is Japanese)

```
setlocale -locale 3
```

The resulting output:

```
No feedback
```

An invocation example (where 8 is Korean)

```
setlocale -locale 8
```

The resulting output:

```
No feedback
```

svqueryclock

Use the **svqueryclock** command to return the date, time, and current time-zone of the system.

Syntax

➤ svqueryclock ➤

Parameters

None

Description

This command returns the date, time and current time-zone of the system.

An invocation example

```
svqueryclock
```

The resulting output:

```
Mon Nov 25 14:59:28 GMT 2013
```

writesernum

Use the **writesernum** command to write the node serial number into the planar NVRAM.

Syntax

```
➤ writesernum — -sernum — serial_number — node_id — node_name ➤
```

Parameters

-sernum *serial_number*

(Required) Specifies the serial number to write to the nonvolatile memory of the system planar.

node_id / *node_name*

(Required) Specifies the node where the system planar is located. The serial number is written to this system planar. This name is not the worldwide node name (WWNN).

Description

This command writes the node serial number into the planar NVRAM and then reboots the system. You can find the serial number at the front of the node without having to remove it from the rack. The seven-digit alphanumeric serial number is located on a label on the front of the node. The serial number on the label might contain a hyphen. Omit this hyphen when typing the serial number with the **writesernum** command.

Note: Once you have written the serial number to the planar NVRAM, you can issue the **lsnodevpd** command to verify that the number is correct. The `system_serial_number` field contains the serial number.

An invocation example

```
writesernum -sernum 1300027 node1
```

The resulting output:

```
No feedback
```

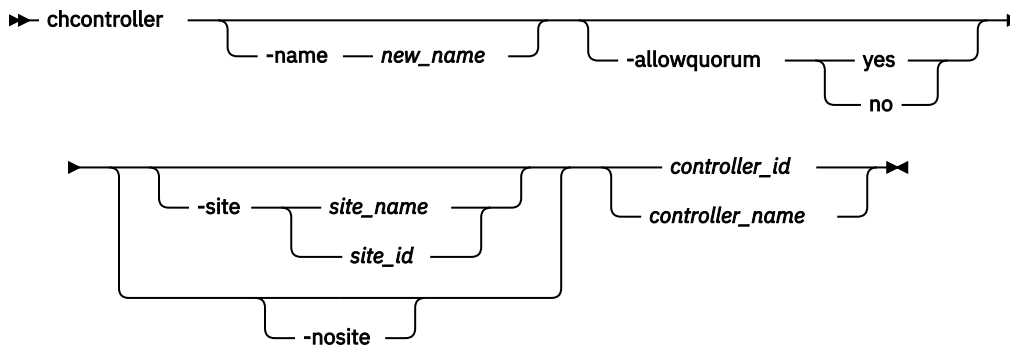

Chapter 9. Controller commands

Use the controller commands to modify the name of a storage controller.

chcontroller

Use the **chcontroller** command to modify the attributes of a controller.

Syntax

Parameters

-name new_name

(Optional) Specifies the new name to be assigned to the controller.

-allowquorum yes | no

(Optional) Specifies that the controller is allowed or is not allowed to support quorum disks. A value of **yes** enables a suitable controller to support quorum disks. A value of **no** disables a controller from supporting quorum disks, provided that the specified controller is not currently hosting a quorum disk.

-site site_name / site_id

(Optional) Specifies the numeric site value or site name for the controller. The value is 1, 2, or 3.

Note: The controller site cannot be changed if the system topology is stretched or hyperswap (and there are MDisk).

-nosite

(Optional) Resets the site value for the controller.

controller_id / controller_name

(Required) Specifies the controller to modify. Use either the controller name or the controller ID.

Description

This command changes the name of the controller that is specified by the *controller_id / controller_name* variable to the value that you specify with the **-name** parameter.

If any controller that is associated with an MDisk shows the **allow_quorum** attribute set to **no** with the **lscontroller** command, the set quorum action fails for that MDisk. Before using the **chcontroller** command to set the **-allowquorum** parameter to **yes** on any disk controller, check the following website to see whether the controller supports quorum.

www.ibm.com/support

You can add a new disk controller system to your SAN at any time. Follow the switch zoning guidelines in the section about switch zoning. Also, ensure that the controller is set up correctly for use with the system.

To add a new disk controller system to a running configuration, ensure that the system has detected the new storage MDisks by issuing the **detectmdisk** command. The controller has automatically been assigned a default name. If you are unsure of which controller is presenting the MDisks, issue the **lscontroller** command to list the controllers. The new controller is listed with the highest numbered default name. Record the controller name and follow the instructions in the section about determining a disk controller system name.

Give this controller a descriptive name by issuing the following command:

```
chcontroller -name newname oldname
```

List the unmanaged MDisks by issuing the following command:

```
lsmdisk -filtervalue mode=unmanaged:controller_name=newname
```

These MDisks correspond to the RAID arrays or partitions that you have created. Record the field controller LUN number. The field controller LUN number corresponds with the LUN number that you assigned to each of the arrays or partitions.

Create a new storage pool and add only the RAID arrays that belong to the new controller to this storage pool. Avoid mixing RAID types; for each set of RAID array types (for example, RAID-1 or RAID-10), create a new storage pool. (You cannot use RAID-10 with distributed arrays.) Assign this storage pool an appropriate name; if your controller is called FAST650-abc and the storage pool contains RAID-10 arrays, assign the MDisk a name similar to F600-abc-R5. Issue the following command:

```
mkmdiskgrp -ext 16 -name mdisk_grp_name  
-mdisk colon-separated list of RAID-x mdisks returned
```

Note: This creates a new storage pool with an extent size of 16 MB.

An invocation example

```
chcontroller -name newtwo 2
```

The resulting output:

```
No feedback
```

An invocation example

```
chcontroller -site site1 controller18
```

The resulting output:

```
No feedback
```

Related reference

[lscontroller](#)

Use the **lscontroller** command to display a concise list or a detailed view of controllers that are visible to the system.

[lscontrollerdependentvdisks](#)

Use the **lscontrollerdependentvdisks** command to list the volumes that depend on the specified controller.

lscontroller

Use the **lscontroller** command to display a concise list or a detailed view of controllers that are visible to the system.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are returned. If a capacity is specified, the units must also be included.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the CLI:

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard, which must be the first or last character in the string.

-filtervalue?

(Optional) Displays the valid filter attributes. The following filter attributes for the **lscontroller** command are valid:

- controller_name
- id
- site_id
- site_name

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

controller_id / controller_name

(Optional) Specifies the name or ID of a controller. When you use this parameter, the detailed view of the specific controller is returned and any value that is specified by the **-filtervalue** parameter is ignored. If you do not specify the **controller_id / controller_name** parameter, the concise view displays

all controllers that match the filtering requirements that are specified by the **-filtervalue** parameter.

Description

This command returns a concise list, or a detailed view, of controllers visible to the system.

The following values are applicable to the data in the output views:

degraded no, yes

To differentiate the name of a storage controller from the name that is shown on the system, list the storage controllers by issuing the **lscontroller** command. Record the controller name or ID for the controller that you want to determine. For the controller in question, issue the **lscontroller controller name / id** command, where *controller name / id* is the controller name or ID. Record the worldwide node name (WWNN) for the controller. You can use the WWNN to determine the actual storage controller by launching the native controller user interface, or by using the command line tools that it provides to verify the actual controller that has the WWNN.

Notes:

1. The *mdisk_link_count* value is the number of MDisk currently associated with this storage controller.
2. The *max_mdisk_link_count* value is the highest value that the *mdisk_link_count* reaches since it was last reset to the *mdisk_link_count* value.

Remember: This value is reset by specific maintenance procedures or when the event log is cleared.

3. A SAN connection from a node or node canister port to a controller port for a single MDisk is a path. The controller port *path_count* value is the number of paths that are currently being used to submit input/output (I/O) data to this controller port.
4. The storage controller *max_path_count* value is the highest value that the storage controller *path_count* reaches since it was last reset to the *path_count* value. This value is reset by specific maintenance procedures or when the system error log is cleared.

Important: The *max_path_count* value is the highest value that the *path_count* reaches since it was last reset to the *path_count* value.

Remember: This value is reset by specific maintenance procedures or when the event log is cleared.

5. The *allow_quorum* value identifies if the controller is enabled to support quorum disks. Quorum support is either enabled or disabled depending on the controller hardware type.
6. The *ctrl_s/n* value is the controller serial number.

Important: This data comes from vendor-controlled sources and might not be available.

This table provides the attribute values that can be displayed as output view data.

This table provides the attribute values that can be displayed as output view data.

Table 71. lscontroller output	
Attribute	Possible Values
id	Indicates the controller ID.
name	Indicates the controller name.
WWNN	Indicates the worldwide node name (WWNN). This field is blank for iSCSI controllers.
mdisk_link_count	Indicates the MDisk link count.
max_mdisk_link_count	Indicates the maximum MDisk link count.
degraded	Indicates whether the controller has degraded MDisk.

Table 71. lscontroller output (continued)	
Attribute	Possible Values
vendor_id	Indicates the vendor identification name or number.
product_id_low	Indicates the product identification.
product_id_high	Indicates the product identification.
product_revision	Indicates the product revision.
ctrl_s/n	Indicates the controller serial number.
allow_quorum	Indicates that the controller can support quorum disks.
WWPN	Indicates the worldwide port name (WWPN). This field is blank for iSCSI controllers.
path_count	Indicates the number of paths that are currently being used to submit input/output (I/O) data to the controller port.
max_path_count	Indicates the maximum number of paths that are currently being used to submit input/output (I/O) data to the controller port.
site_id	Indicates the site value for the controller. This numeric value is 1, 2, 3, or blank.
site_name	Indicates the site name for the controller. This value is an alphanumeric value or is blank.
fabric_type	Indicates a Fibre Channel (FC) or SAS controller. <ul style="list-style-type: none"> • fc indicates an FC controller • sas_direct indicates an SAS direct-attached controller • multiple indicates multiple controllers (either FC, SAS, or both) • iscsi indicates an iSCSI controller
iscsi_port_id	Indicates the I/O port identifier, which is the same as the WWPN value from the FC domain. This value shows the iSCSI port ID for the iSCSI controller and is blank for other controllers. This value must be a numeric value. This ID refers to the row number in output from the lsiscsistorageport command. The lsiscsistorageport can be used to find the controller IQN.
ip	Indicates the IP address that is associated with the iscsi_port_id . This value shows the IP value for the iSCSI controller and is blank for other controllers. This value must be an IPv4 or IPv6 address.

Table 71. lscontroller output (continued)	
Attribute	Possible Values
physical_capacity	Indicates the physical capacity of the controller. This value is always blank or empty for controllers that do not report physical capacity information.

A concise invocation example for an iSCSI controller

```
lscontroller -delim :
```

The concise resulting output:

```
id:controller_name:ctrl_s/
n:vendor_id:product_id_low:product_id_high:WWNN:degraded:fabric_type:site_id:site_name

[chcontroller](#)

Use the **chcontroller** command to modify the attributes of a controller.

[lscontrollerdependentvdisks](#)

Use the **lscontrollerdependentvdisks** command to list the volumes that depend on the specified controller.

lscontrollerdependentvdisks

Use the **lscontrollerdependentvdisks** command to list the volumes that depend on the specified controller.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

controller_id_list | controller_name_list

Specifies one or more controller IDs, controller names, or both. Separate multiple controllers using the colon character (:).

Description

The **lscontrollerdependentvdisks** command lists the volumes that depend on the status of the specified controllers. If a controller goes offline, the dependent volumes also go offline. Before you take a controller offline for maintenance, you can use the command to ensure that you do not lose access to any volumes.

If you have multiple controllers that are configured as a single subsystem, you must specify all of the controllers in the subsystem. When you do this you must specify a single command invocation.

The **lscontrollerdependentvdisks** command also checks for quorum disks on the specified controller list. If any quorum disks are on the specified controller list, the command returns an error. All quorum disks must be moved before you perform any maintenance. After you move quorum disks, reissue the command to list the dependent volumes.

Note: The command lists the volumes that depend on the controllers at the time the command is run; subsequent changes to your system require rerunning the command.

An invocation example

```
lscontrollerdependentvdisks controller0
```

The concise resulting output:

```
vdisk_id vdisk_name
0 vdisk0
1 vdisk1
2 vdisk2
```

Chapter 10. Drive commands

Use the drive commands to capture information to assist with managing drives.

applydrivesoftware

Use the **applydrivesoftware** command to update drives.

Syntax

```
➤ applydrivesoftware — -file — name — -type — firmware | fpga — -drive — drive_id — -all — -force — -allowreinstall — -allowdowngrade — -cancel ➤
```

The diagram illustrates the syntax of the **applydrivesoftware** command. It is structured as follows:

- Required parameters:** `-file` followed by `name`.
- Optional parameters:**
 - `-type` with values `firmware` or `fpga`.
 - `-drive` followed by `drive_id`.
 - `-all`.
 - `-force`.
 - `-allowreinstall`.
 - `-allowdowngrade`.
- Termination:** The command ends with `-cancel`.

Parameters

-file *name*

(Required) Specifies the firmware update file name that must be copied to the `/home/admin/update/` directory on the configuration node.

-type *fpga* | *firmware*

(Optional) Specifies the type of drive firmware to update. Drive firmware updates can be performed online, concurrently with I/O. However, `fpga` updates require the drive to be taken offline, which means target drives must be made candidate before issuing the **applydrivesoftware** command. The default value is `firmware`. See the **chdrive** command for more details.

-all

(Optional) Specifies that the drive firmware should be applied to every drive in the system, as long as that drive is online and has use `member`, use `spare`, or use `candidate`.

This does not apply to:

- Drives that have dependent volumes
- Drives that are members of non-redundant arrays

Drives hosting quorum qualify, but there is risk. To avoid this risk use **-drive** and make sure the quorum is moved in between **applydrivesoftware** invocations. Use the **chquorum** command to avoid updating a drive that is hosting quorum.

If you specify **-all** you must specify the **-type** as `firmware`.

Remember: The **-all** parameter differs from the **-drive** parameter because unsuitable drives are not added to the list of drives scheduled for update when you use **-all**.

-drive *drive_id*

(Optional) Specifies one drive ID or a list of drive IDs (separated by a colon, `[:]`) to be updated. The maximum number of IDs is 128. If you have more than 128, use **-all** or multiple **applydrivesoftware** invocations to complete the update.

Remember: The **-drive** parameter differs from the **-all** parameter because if you specify an unsuitable drive using the **-drive** parameter, the **applydrivesoftware** command fails. Additionally, if you specify all three drives as hosting quorum, the command fails. If you use the **-drive** option to specify a single drive, and that drive has use=unused, it is updated.

-force

(Optional) Bypasses the dependent volume check. By default **applydrivesoftware** cannot run if any volumes dependent on the drive. Specifying **-force** bypasses this check, allowing the drive software update to proceed. Drive-dependent volumes generally result from non-redundant or degraded RAID arrays.

Note: Restore redundancy to the system (where possible) instead of using the **-force** parameter.

Important: Using the **-force** parameter might result in a data loss. Use it only under the direction of your product support information, or if you are willing to accept the risk of data loss in the array or pool to which the drive belongs.

-allowreinstall

(Optional) Specifies to make the system install the current level (again) onto drives that contain a file in the package.

Remember: Using this parameter is not recommended.

-allowdowngrade

(Optional) Specifies to allow the system to downgrade the firmware on a drive (that contains a file in the package).

Remember: Use this parameter only under the direction of your product support information.

-cancel

(Optional) Specifies that the command be stopped.

Description

Use this command to update the firmware of drives that are managed by the system.

There are two types of drive software that can be updated using this command:

- **firmware**
- **fpga**

Drive firmware updates can be performed online while the drive is in use. When used on an array member drive **applydrivesoftware** checks for volumes that are dependent on the drive and refuses to run if any are found. Drive dependent volumes are usually caused by non-redundant or degraded RAID arrays. Where possible you should restore redundancy to the system by replacing any failed drives before using the **applydrivesoftware** command. When this is not possible, for example on drives that are members of a RAID-0 array, you can either add redundancy to the volume by adding a second copy in another pool, or use the **-force** parameter to bypass the dependant volume check.

Remember: Only use **-force** if you are willing to accept the risk of data loss on dependent volumes (if the drive fails during the firmware update).

Drive firmware updates occur asynchronously, and conclude after the **applydrivesoftware** command completes. To see the status of the updates, use the **lsdriveupgradeprogress** command.

Drive fpga updates might require the drive to be taken offline for several minutes. Drives must be changed to the candidate state before **applydrivesoftware** can be used to update fpga software. The fpga updates occur asynchronously, continuing in the background after the **applydrivesoftware** command has returned. You must check the **FPGA_level** field in **lsdrive N**, where *N* is the *drive_id*, to see whether or not the update completed successfully.

Remember: Interrupting an fpga update by removing power from the drive or enclosure might make the drive unusable. Only one drive's fpga can be updated per **applydrivesoftware** invocation. Make sure that the update is complete before unseating the drive or removing power from the enclosure.

An invocation example

```
applydrivesoftware -file DRIVE_XXXXXXX -type firmware -drive 4
```

The resulting output:

No feedback

An invocation example

An example that fails because of drive-dependent volumes:

```
applydrivesoftware -file DRIVE_XXXXXXX -type firmware -drive 6
```

The resulting output:

CMMVC6953E The action cannot be completed because vdisks are dependent on the specified mdisk. Force is required.

An invocation example

```
applydrivesoftware -file drivemicrocodepackagev5 -type firmware -all
```

The resulting output:

No feedback

An invocation example

```
applydrivesoftware -file drivemicrocodepackagev1 -type firmware -all -  
allowreinstall
```

The resulting output:

No feedback

An invocation example

```
applydrivesoftware -file drivemicrocodepackagev1 -type firmware -all -  
allowdowngrade
```

The resulting output:

No feedback

An invocation example

```
applydrivesoftware -file drivemicrocodepackagev1 -type firmware -all -  
allowdowngrade -allowreinstall
```

The resulting output:

No feedback

An invocation example

```
applydrivesoftware -cancel
```

The resulting output:

No feedback

chdrive

Use the **chdrive** command to change the drive properties.

Syntax

Parameters

-use unused | candidate | spare | failed

Describes the role of the drive:

- **unused** indicates that the drive is not in use and will not be used as a spare.
- **candidate** indicates that the drive is available for use in an array.
- **spare** indicates that the drive can be used as a hot-spare drive if required.
- **failed** indicates that the drive has failed.

Note: To create member drives, add the drives to (new) arrays by using the **mkarray** command.

If a drive fails for a distributed array, the array remains associated with the failed drive while it is in the **failed** state.

Note: If **chdrive -use candidate** is run on a compressed drive, it causes the drive to perform a format. The format must complete before the drive becomes online and available for use.

-allowdegraded

(Optional) Permits permission for a change of drive use to continue, even if a hotspare drive is not available for the array that the drive is a member of. You cannot specify **-allowdegraded** and **-task** together. You cannot specify **-allowdegraded** when an array expansion is in progress.

Important: Avoid using **-allowdegraded**.

-task format | certify | recover | erase

Causes the drive to perform a task:

- **format** indicates that a drive will be formatted for use in an array; only permitted when drive is a candidate or has failed validation.

Note: For NVMe drives, formatting the drive completes a cryptographic erase of the drive.

- **certify** indicates that the drive will be analyzed to verify the integrity of the data it contains; permitted for any drive that is a member.

Note: **certify** is not supported in NVMe drives.

- **recover** recovers an offline flash drive without losing data; permitted when the drive is offline because a build is required, or when the drive has failed validation.

Note: **recover** is not supported in NVMe drives.

- **erase** causes a sanitize disk erase operation. The type of erase is either cryptographic, block, or overwrite. The type of erase depends on the SAS drive manufacturer, drive type, and firmware.

Note: This parameter is not available on NVMe drives or cloud systems.

drive_id

The identity of the drive.

Description

Use this command to change the drive role, or to start long running drive tasks.

You can use **lsdriveprogress** to display progress (percentage) and estimated completion time of ongoing drive tasks.

When a drive that is associated with a distributed array is changed from **member** to **failed**, if the distributed array does not have available rebuild space then it is degraded. If **-allowdegraded** is not specified, the command fails because of insufficient rebuild areas. If the **-allowdegraded** parameter is specified, the command succeeds and the array no longer uses the drive for I/O operations. If a drive is changed from **failed** to another configuration, the information for that drive is removed and the distributed array creates a missing member that belongs in the member table. Use the **chararraymember** command to replace the missing member.

An invocation example

```
chdrive -use spare 1
```

The resulting output:

```
No feedback
```

An invocation example to certify drive 23

```
chdrive -task certify 23
```

The resulting output:

```
No feedback
```

lsdrive

Use the **lsdrive** command to display configuration information and drive vital product data (VPD).

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (""): **lsdrive -filtervalue mdisk_id="1★"**

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue?

(Optional) Displays the valid filter attributes for the **-filtervalue** parameter:

- capacity
- enclosure_id
- error_sequence_number

- id
- interface_speed
- mdisk_id
- mdisk_name
- member_id
- node_id
- node_name
- slot_id
- status
- tech_type
- use
- drive_class_id
- transport_protocol

-bytes

(Optional) The size (capacity) of the drive in bytes.

drive_id

(Optional) The identity of the drive.

Description

Use this command to display configuration information and drive VPD.

Note: Filtering should be permitted on all concise fields.

Note: A backup of system state is stored on quorum disks, which contributes to the physically used space. The amount of data that is used for this backup depends on the system configuration, but is typically a few MB and cannot exceed 1 GB.

This table describes possible outputs.

<i>Table 72. lsdrive output</i>	
Attribute	Value
id	<p>Indicates the ID of the drive:</p> <ul style="list-style-type: none"> • online, which indicates that the drive is available through all drive ports. • degraded, which indicates that the drive is available but not through all drive ports. • offline, which indicates that the drive is unavailable.
status	Indicates the summary status of the drive.
error_sequence_number	<p>Indicates the error sequence number that describes the cause of the drive status:</p> <ul style="list-style-type: none"> • online, which is blank. • degraded, which is populated if associated with an error. • offline, which must be populated. <p>Note: Error sequence numbers indicate an entry in the event log. This value includes entries that are both errors, and informational messages (for example, the drive is formatting).</p>

Table 72. lsdrive output (continued)	
Attribute	Value
use	<p>Indicates the current role of the drive:</p> <ul style="list-style-type: none"> • unused if the drive is not configured to be used by anything. • candidate if the drive is available to be configured. • spare if the drive is configured as a spare, to be used if the arrays fail members. • member if the drive is configured as a member of an array. • failed if the drive is rejected and is no longer available for use.
UID	Indicates that the unique ID reported by the drive.
tech_type	<p>Indicates the drive technology used.</p> <p>The values are:</p> <ul style="list-style-type: none"> • unsupported indicates that the drive is not supported in this platform (contact your support team). • tier_scm • tier0_flash • tier1_flash • tier_enterprise • tier_nearline
replacement_date	Indicates the date of a potential drive failure. The format must be YYMMDD. This value is blank for non-SSD drives.
capacity	<p>Indicates the capacity of the disk, excluding quorum area.</p> <p>For compressed drives, this output represents the logical capacity of the drive, which is greater than the physical capacity, and is determined by the number of addressable logical blocks that are presented by the drive.</p> <p>For non-compressed drives, the capacity value is the same for both logical and physical capacity.</p>
block_size	Indicates the block size of the disk.
vendor_id	Indicates the manufacturer of the drive.
product_id	Indicates the product ID of the drive.
FRU_part_number	Indicates the FRU part number of the drive.
FRU_identity	Indicates the 11S number that combines manufacturing part number and serial number.
RPM	Indicates the specified RPM of the disk.
firmware_level	Indicates the firmware level of the disk; blank if unknown.
FPGA_level	Indicates the FPGA level, if applicable; blank if not applicable or unknown.
mdisk_id	Indicates the ID of the array MDisk that the drive is a member of.
mdisk_name	Indicates the name of the MDisk that the drive is a member of.
member_id	Indicates the ID of the MDisk array member.

Table 72. lsdrive output (continued)	
Attribute	Value
enclosure_id	Indicates whether the: <ul style="list-style-type: none"> • Drive is contained in an enclosure (not a node) and the slot position is known. This value is the ID of the enclosure in which the drive is located. • Drive is contained in a node (not an enclosure). This value is blank. • Enclosure ID is not determined yet. This value is blank.
slot_id	Indicates the slot_id of the drive in the enclosure or node. It can be referred to as the drive bay or location. This value can be blank.
node_name	Indicates the node name where the drive is located for a drive that is contained within a node. For a drive contained within an enclosure, it is blank.
node_id	Indicates the node ID where the drive is located for a drive that is contained within a node. For a drive contained within an enclosure, the value is blank.
quorum_id	Indicates the ID of quorum disk. The value is blank if not quorum disk.
port_1_status	Indicates the connectivity status of the drive's first port. The values are online, offline, or excluded. Note: Port 1 is attached to the node that has a panel name that ends in -1.
port_2_status	Indicates the connectivity status of the drive's second port. The values are online, offline, or excluded. Note: Port 2 is attached to the node that has a panel name that ends in -2.
interface_speed	Indicates the lowest interface speed for the connected drive slot (in gigabits per second, or Gbps). The values are: <ul style="list-style-type: none"> • 1.5 Gbps • 3 Gbps • 6 Gbps • 12 Gbps • Blank if both ports are isolated or the drive is not connected.
protection_enabled	Indicates whether SCSI type-2 protection information is enabled (yes) or not (no).
auto_manage	Indicates whether the auto_manage process is running (active) or not running (idle).
drive_class_id	Indicates which drive class the drive is part of.

Table 72. lsdrive output (continued)	
Attribute	Value
write_endurance_used	<p>Indicates the drive writes per day (DWPD). This value is blank for drives that are not SSD drives. The value must be a number 0 - 255.</p> <p>This value indicates the percentage of life that is used by the drive. The value 0 indicates that full life remains, and 100 indicates that the drive is at or past its end of life.</p> <p>Note: The drive must be replaced when the value exceeds 100.</p> <p>This value is blank for drives that are either:</p> <ol style="list-style-type: none"> 1. Not SSDs. 2. SSDs that predate support of the endurance indicator. <p>This value also applies to drives that are yet to be polled, which can take up to 24 hours.</p>
write_endurance_usage_rate	<p>Indicates the DWPD usage rate. The values are:</p> <ul style="list-style-type: none"> • measuring • high • marginal • low <p>This value is blank for non-SSD drives.</p> <p>Note: This field displays a value only when the write_endurance_used value changes.</p>
transport_protocol	<p>Indicates the transport protocol of the drive. Blank for Flashsystem V9000 AE1 and AE2 enclosures. The possible values are:</p> <ul style="list-style-type: none"> • sas • nvme
compressed	<p>Indicates whether the drive is compressed. A drive that is compressed contains an on-board compression function that is applied to all data written to the drive.</p>
physical_capacity	<p>For compressed drives, this output represents the total amount of physical storage on the drive. This value is smaller than the logical capacity presented by the capacity value.</p> <p>For non-compressed drives, the physical_capacity is the same as the logical capacity.</p>
physical_used_capacity	<p>Indicates the amount of physical storage capacity that is used on the drive. If the drive is not compressed, no value is presented here.</p>
effective_used_capacity	<p>Indicates the amount of logical data that is written to the drive. If the drive is not compressed, no value is presented here.</p>
date_of_manufacture	<p>Indicates the manufacture date for SAS drives (YYMMDD).</p>

A concise invocation example

```
lsdrive -delim :
```

The concise resulting output:

lsdriveclass

Use the **lsdriveclass** command to display all drive classes in the system.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-filtervalue attribute=value

(Optional) Specifies a list of one or more filter attributes that match the specified values; see **-filtervalue?** for the supported attributes.

Note: Some filters allow the use of a wildcard when you specify the command. The following rules apply to the use of wildcards when you use the CLI:

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard, which must be the first or last character in the string.
- When you specify a wildcard character, you must enclose the filter entry within double quotation marks (" "), as follows:

```
lsdriveclass -filtervalue "IO_group_name=md*"
```

-filtervalue?

(Optional) Includes all of the valid filter attributes in the report. The following filter attributes are valid for the **lsdriveclass** command:

- id
- RPM
- capacity
- IO_group_id
- IO_group_name
- tech_type
- block_size

- candidate_count
- superior_count
- total_count
- compressed
- physical_capacity
- transport_protocol

Any parameters that are specified with the **-filtervalue?** parameter are ignored.

-delim delimiter

(Optional) By default, in a concise view all columns of data are space-separated, with the width of each column set to the maximum width of each item of data. In a detailed view, each item of data is an individual row, and if you display headers, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. Specify **-delim :** on the command line, and the colon character (:) separates all items of data in a concise view (for example, the spacing of columns does not occur); in a detailed view, the specified *delimiter* separates the data from its header.

drive_class_id

(Optional) The identity of the drive class.

Description

This command displays all drive classes in a system. Drives are displayed if they are managed.

This table provides the attribute values that can be displayed as output view data.

<i>Table 73. lsdriveclass output</i>	
Attribute	Possible Values
id	Indicates the drive class ID.
RPM	Indicates the speed of the drive class.
capacity	Indicates the capacity of the drive class.
IO_group_id	Indicates the I/O group ID associated with the drive class.
IO_group_name	Indicates the I/O group name that is associated with the drive class.
tech_type	Indicates the technology type of the drive class. <ul style="list-style-type: none"> • tier0_flash • tier1_flash • tier_enterprise • tier_nearline • tier_scm
block_size	Indicates the block size of the drive class.
candidate_count	Indicates the number of drives in the drive class that are in candidate state.
superior_count	Indicates the total number of drives in this class and the drives that count as superior. (This value applies to distributed arrays created by using mkdistributedarray .)

Table 73. <i>lsdriveclass</i> output (continued)	
Attribute	Possible Values
total_count	Indicates the total number of drives in the drive class. The drive state is irrelevant.
transport_protocol	Indicates the transport protocol of the drive. Blank for Flashsystem V9000 AE1 and AE2 enclosures. The possible values are: <ul style="list-style-type: none"> • sas • nvme
compressed	Indicates whether the drive is compressed.
physical_capacity	For compressed drives, this output represents the total amount of physical storage on the drive. This value can be smaller than the logical capacity presented by the capacity value. For non-compressed drives, the physical_capacity is the same as the logical capacity.

A concise invocation example

```
lsdriveclass -filtervalue block_size=4096
```

The detailed resulting output:

```

id   RPM    capacity  IO_group_id  IO_group_name  tech_type  block_size  candidate_count
superior_count total_count
3    15000  600.5GB   2            io_group2      tier0_flash  4096        0
0
```

A concise invocation example

```
lsdriveclass -filtervalue io_group_ID=0:tech_type=tier_enterprise
```

The detailed resulting output:

```

id   RPM    capacity  IO_group_id  IO_group_name  tech_type  block_size  candidate_count
superior_count total_count
0    10000  300.9GB   0            io_group0      tier0_flash  512        30
3
```

A concise invocation example

```
lsdriveclass -delim ! -nohdr
```

The detailed resulting output:

```

0!10000!300.9GB!0!io_group0!tier_nearline!512!30!30
1!1600.5GB!0!io_group0!tier_nearline!512!10!50
2!15000!900.1GB!1!io_group1!tier_enterprise!512!60!60
3!15000!600.5GB!2!io_group2!tier_enterprise!4096!0!24
```

A detailed invocation example

```
lsdriveclass 2
```

The detailed resulting output:

```
id 2
RPM 15000
capacity 900.1GB
IO_group_id 1
IO_group_name io_group1
tech_type tier0_flash
block_size 512
candidate_count 60
superior_count 5
total_count 60
```

[triggerdrivedump](#)

Use the **triggerdrivedump** command to collect support data from a disk drive. This data can help you understand problems with the drive and does not contain any data that applications write to the drive.

lsdrivelba

Use the **lsdrivelba** command to map array MDisk logical block address (LBA) to a set of drives.

Syntax

```
►► lsdrivelba -nohdr -delim delimiter -mdisklba lba ►
      └──┬──┘
      │  │
      │  └── mdisk_id
      └── mdisk_name
```

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim *delimiter*

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a

concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-mdisklba lba

(Required) The logical block address (LBA) on the MDisk. The LBA must be specified in hex, with a 0x prefix.

-mdiskmdisk_id | mdisk_name

(Required) The ID or name of the MDisk.

Description

This command maps the array MDisk LBA to a set of drives.

The system provides volumes that have LBAs for 512-byte block sizes, but back-end disks that have a block size of either 512 or 4096 bytes can also be used. Drives are listed in their physical size.

Use the **lsdrive** command to display the drive block size, and use the **lsdrive** or **lsarray** command to list each object (the drive and the MDisk).

This table describes possible outputs.

Table 74. lsdrivelba output	
serial-attached SCSI (SAS) Attribute	Value
drive_id	The ID of drive; blank if no configured array member exists (for example, in a degraded array).
type	The type of information on the disk: <ul style="list-style-type: none"> • parity, in which LBA range contains parity (RAID levels 5 and 6 only) • qparity, in which LBA range contains qparity (RAID level 6 only) • data, in which LBA range contains data
drive_lba	The LBA on the drive.
drive_start	The start of range of LBAs (strip) on the drive.
drive_end	The end of range of LBAs (strip) on the drive.
mdisk_start	The start of range of LBAs (strip) on the array MDisk.
mdisk_end	The end of range of LBAs (strip) on the array MDisk.

An invocation example

```
lsdrivelba -delim : -mdisklba 0x000 -mdisk 2
```

The resulting output:

```
drive_id:type:drive_lba:drive_start:drive_end:mdisk_start:mdisk_end
0:data:0x0000000000000000:0x0000000000000000:0x0000000000000200:0x0000000000000000:0x0000000000000000

lsdriveprogress

Use the **lsdriveprogress** command to view the progress of various drive tasks.

Syntax

Parameters

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the SAN Volume Controller CLI:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (" "), as follows:

```
lsdriveprogress -filtervalue "task=*"
```

-filtervalue?

(Optional) Displays the valid filter attributes for the **-filtervalueattribute=value** parameter:

- task

drive_id

(Optional) The drive for which you want to view progress.

Description

The following outputs are possible:

drive_id

Indicates the ID for the drive with the active task.

task

Indicates the type of task:

- format
- certify
- **erase**
- recover

progress

Indicates the percentage completion for a job.

estimated_completion_time

Indicates the estimated completion time, in the format YYMMDDHHMMSS, where:

- Y is the year.
- (The first) M is the month.
- D is the day.
- H is the hour.
- (The second) M is the minute.
- S is the second.

An invocation example

```
lsdriveprogress -delim :
```

The resulting output:

```
drive_id:task:progress:estimated_completion_time
0:format:10:091118131056
9:erase:25:991231235959
```

An invocation example

```
lsdriveprogress -delim :
```

The resulting output:

```
drive_id:task:progress:estimated_completion_time
0:format:10:091118131056
9:certify:25:991231235959
```

An invocation example

```
lsdriveprogress -delim : 9
```

The resulting output:

```
9:certify:25:991231235959
```

lsdriveupgradeprogress

Use the **lsdriveupgradeprogress** command to view the status or progress of drives with pending downloads.

Syntax

➔ **lsdriveupgradeprogress** 

Parameters

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum possible width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a one-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

drive_id

(Optional) Specifies the update status or progress for a single drive. If not specified, the update status for all scheduled drives is displayed.

Note: If you specify this parameter, **lsdriveupgradeprogress** displays the update status of this drive. If you do not specify this parameter, **lsdriveupgradeprogress** displays the update status of all requested drives.

Description

The **lsdriveupgradeprogress** command completes whether the original **applydrivesoftware** command was addressed to a single drive (synchronous command) or multiple drives (asynchronous command).

The following outputs are possible:

id

Indicates the identity of the active drive.

status

Indicates the drive status. Each of the following values has a specific meaning:

- **progressing** indicates all scheduled drives have completed; wait 270 seconds before you issue **applydrivesoftware** again.
- **completed** indicates a successful firmware download.
- **updating** indicates the update is ongoing.
- **scheduled** indicates the update is in the download list, waiting to download.
- **not_scheduled** indicates the drive is not scheduled.

Note: This means the corresponding drive was not scheduled when **applydrivesoftware -all** was last issued.

- **canceled** indicates the update has been canceled, either by command or by a system change that stops the **applydrivesoftware** command from running properly.
- **invalid** indicates the drive download status is invalid, also the initial state.
- If the field is blank, that indicates that the download is not scheduled (for example, the **applydrivesoftware** command has not been issued).

estimated_completion_time

Indicates the estimated completion time (YYMMDDHHMMSS), where:

- Y is year
- (The first) M is month
- D is day
- H is hour
- (The second) M is minute
- S is second

The value is blank if the status is either canceled or blank.

A concise invocation example with two drives canceled

```
lsdriveupgradeprogress
```

The resulting output:

```
id status      estimated_completion_time
0  completed  121112062608
5  canceled
6  canceled
```

A concise invocation example with drives scheduled or completed

Use the **triggerdrivedump** command to collect support data from a disk drive. This data can help you understand problems with the drive and does not contain any data that applications write to the drive.

Syntax

►► **triggerdrivedump** — *drive_id* ◄◄

Parameters

drive_id

(Required) The ID of the drive to dump.

Description

Use this command to collect internal log data from a drive and store the information in a file in the /dumps/drive directory. This directory is on one of the nodes connected to the drive. The system limits the number of drive dump files in the directory to 24 per node.

An invocation example

```
triggerdrivedump 2
```

The resulting output:

```
Dump file for drive [2] created
```

Note: The system chooses the node on which to run the statesave.

lsdriveprogress

Use the **lsdriveprogress** command to view the progress of various drive tasks.

lsdriveupgradeprogress

Use the **lsdriveupgradeprogress** command to view the status or progress of drives with pending downloads.

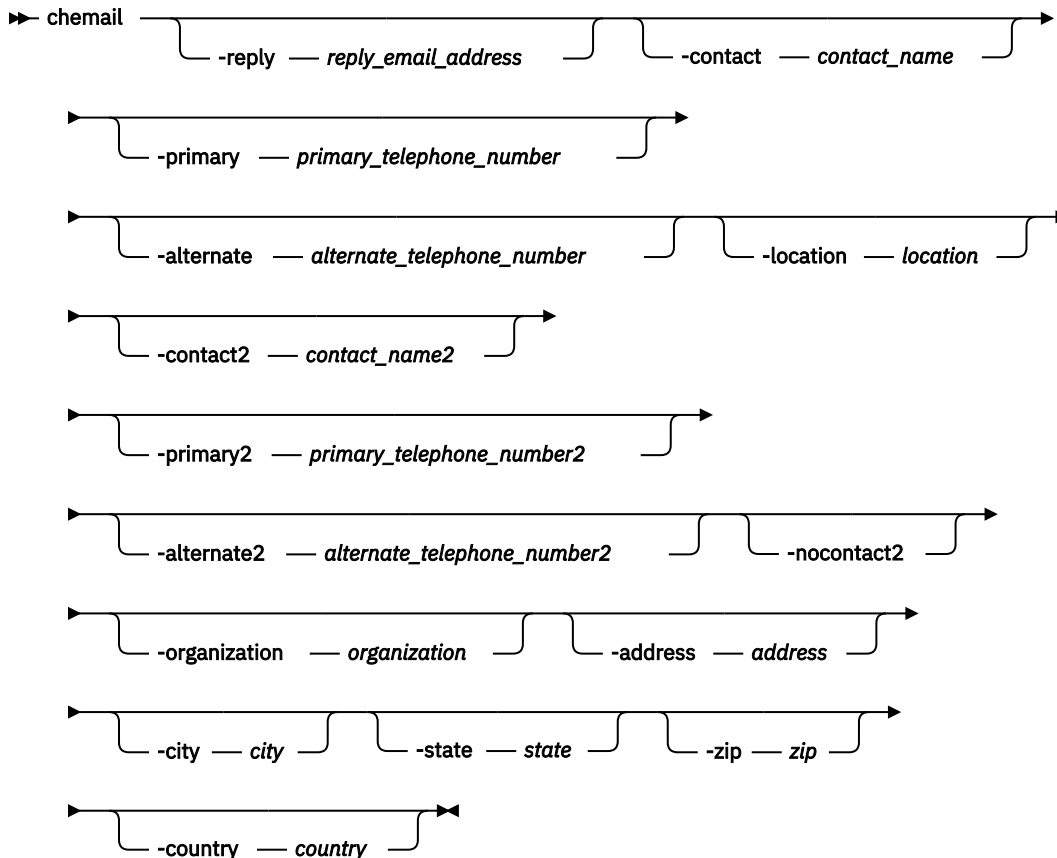

Chapter 11. Email and event notification commands

Use the email and event notification commands to enable your system to send notifications.

chemail

Use the **chemail** command to set or modify contact information for email event notifications. At least one of the parameters must be specified to modify settings.

Syntax

Parameters

-reply *reply_email_address*

(Optional) Specifies the email address to which a reply is sent.

-contact *contact_name*

(Optional) Specifies the name of the person to receive the email.

-primary *primary_telephone_number*

(Optional) Specifies the primary contact telephone number.

Note: For machine types 2071 and 2072 (in the United States and Canada), the value entered must be exactly ten decimal digits. For machines types 2071 and 2072 (in other countries) the value entered can be five to nineteen decimal digits. Otherwise, there can be up to nineteen characters.

-alternate *alternate_telephone_number*

(Optional) Specifies the alternate contact telephone number that is used when you cannot reach the primary contact on the primary phone.

-location *location*

(Optional) Specifies the physical location of the system that is reporting the error. The *location* value must not contain punctuation or any other characters that are not alphanumeric or spaces.

-contact2 *contact_name2*

(Optional) Specifies the name of the second contact person to receive the email.

For machine types 2071 and 2072 the maximum number of characters is 30. For other machine types the maximum number of characters is 72.

-primary2 *primary_telephone_number2*

(Optional) Specifies the primary contact telephone number for the second contact person.

Note: For machine types 2071 and 2072 (in the United States and Canada), the value entered must be exactly ten decimal digits. For machines types 2071 and 2072 (in other countries) the value entered can be five to nineteen decimal digits. Otherwise, there can be up to nineteen characters.

-alternate2 *alternate_telephone_number2*

(Optional) Specifies the alternate contact telephone number for the second contact person.

-nocontact2

(Optional) Removes all the contact details for the second contact person.

-organization *organization*

(Optional) Specifies the user's organization as it should appear in Call Home emails.

-address *address*

(Optional) Specifies the first line of the user's address as it should appear in Call Home email.

-city *city*

(Optional) Specifies the user's city as it should appear in Call Home email.

-state *state*

(Optional) Specifies the user's state as it should appear in Call Home email. This is a two-character value such as NY for New York.

-zip *zip*

(Optional) Specifies the user's zip code or postal code as it should appear in Call Home email.

-country *country*

(Optional) Specifies the country in which the machine resides as it should appear in Call Home email. This is a two-character value such as US for United States.

For machine types 2071 and 2072 this value cannot be US or CA if the value for **primary** or **primary2** telephone number is not blank or exactly 10 digits.

Description

This command sets or modifies contact information that is used by the email event notification facility.

Note: If you are starting the email event notification facility, the **reply**, **contact**, **primary**, and **location** parameters are required. If you are modifying contact information used by the email event notification facility, at least one of the parameters must be specified.

Remember: When considering e-mail addresses:

- Alphanumeric characters and additionally underscore (_), at symbol (@), and dot (.) characters are permitted.
- There must be exactly one @ character in the string, and the @ characters must not start or end the string.
- A plus (+) character is permitted before the @ character.

These fields do not have to be set to start the email notification system, but if the new fields are set they are included in the email event notifications.

An invocation example

```
chemail -reply ddrogba@uk.uefa.com
        -contact 'Didier Drogba'
        -primary 01962817668
        -location 'C block'
        -organization UEFA
        -address '1 Chelsea Blvd'
        -city Fulham
        -zip 0U812
        -machine_country GB
```

The resulting output:

```
No feedback
```

An invocation example

```
chemail -primary 0441234567 -location 'room 256 floor 1'
```

The resulting output:

```
No feedback
```

An invocation example

```
chemail -country US -primary 8458765309
```

The resulting output:

```
No feedback
```

Use the **mkserver** command to create an email server object that describes a remote Simple Mail Transfer Protocol (SMTP) email server.

[mkuser](#)

Use the **mkuser** command to add a recipient of email event and inventory notifications to the email event notification facility. Add up to twelve recipients (one recipient at a time).

[mksnmpserver](#)

Use the **mksnmpserver** command to create a Simple Network Management Protocol (SNMP) server to receive notifications.

rmemailserver

Use the **rmemailserver** command to delete the specified email server object.

rmemailuser

Use the **rmemailuser** command to remove a previously defined email recipient from the system.

rmsnmpserver

Use the **rmsnmpserver** command to delete the specified Simple Network Management Protocol (SNMP) server.

sendinventoryemail

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

setemail (Discontinued)

Attention: The **setemail** command is discontinued. E-mail notification can be configured using the following commands: **mkemailserver**, **chemailserver**, **rmemailserver**, **chemail**, and **lsemailserver**.

startemail

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

testemail

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

chemailserver

Use the **chemailserver** command to modify the parameters of an existing email server object.

Syntax

Parameters

-name server_name

(Optional) Specifies a unique name to assign to the email server object. The name must be a 1-through 63-character string, and cannot start with a hyphen or number. When specifying a server name, emailserver is a reserved word.

-ip ip_address

(Optional) Specifies the IP address of the email server object. This must be a valid IPv4 or IPv6 address. IPv6 addresses can be zero compressed.

-port port

(Optional) Specifies the port number for the email server. This must be a value of 0 - 65535. The default value is 25.

email_server_name / email_server_id

(Required) Specifies the name or ID of the server object to be modified.

Description

Use this command to change the settings of an existing email server object. The email server object describes a remote Simple Mail Transfer Protocol (SMTP) email server.

You must specify either the current name or the ID of the object returned at creation time. Use the **lserver** command to obtain this ID.

An invocation example

```
chemailserver -name newserver 0
```

The resulting output:

```
No feedback
```

[mksnmpserver](#)

Use the **mksnmpserver** command to create a Simple Network Management Protocol (SNMP) server to receive notifications.

[rmemailserver](#)

Use the **rmemailserver** command to delete the specified email server object.

[rmemailuser](#)

Use the **rmemailuser** command to remove a previously defined email recipient from the system.

[rmsnmpserver](#)

Use the **rmsnmpserver** command to delete the specified Simple Network Management Protocol (SNMP) server.

[sendinventoryemail](#)

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

[setemail](#) (Discontinued)

Attention: The **setemail** command is discontinued. E-mail notification can be configured using the following commands: **mkemailserver**, **chemailserver**, **rmemailserver**, **chemail**, and **lsemailserver**.

startemail

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

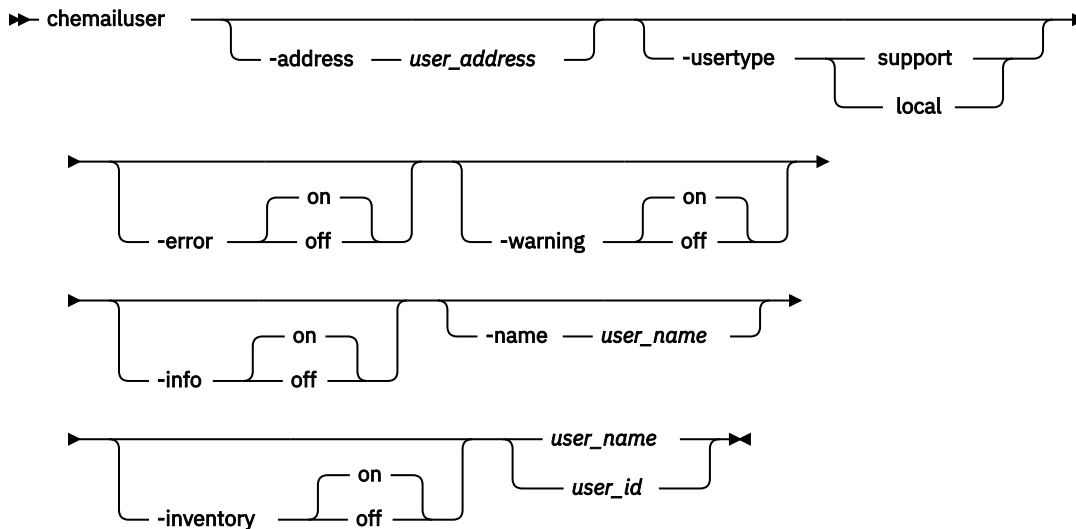

testemail

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

chemailuser

Use the **chemailuser** command to modify the settings that are defined for an email recipient.

Syntax

Parameters

-address user_address

(Optional) Specifies the email address of the person receiving the email or inventory notifications, or both. The *user_address* value must be unique.

-usertype support | local

(Optional) Specifies the type of user, either local or support, based on the following definitions:

support

Address of the support organization that provides vendor support.

local

All other addresses.

-error on | off

(Optional) Specifies whether the recipient receives error-type event notifications. Set to **on**, error-type event notifications are sent to the email recipient. Set to **off**, error-type event notifications are not sent to the recipient.

-warning on | off

(Optional) Specifies whether the recipient receives warning-type event notifications. Set to **on**, warning-type event notifications are sent to the email recipient. Set to **off**, warning-type event notifications are not sent to the recipient.

-info on | off

(Optional) Specifies whether the recipient receives informational event notifications. Set to **on**, informational event notifications are sent to the email recipient. Set to **off**, informational event notifications are not sent to the recipient.

-name *user_name*

(Optional) Specifies the user name of the new email event notification recipient. The *user_name* value must be unique, must not contain spaces, and must not contain all numbers. The name **emailusern**, where *n* is a number, is reserved and cannot be specified as one of your user names.

-inventory on | off

(Optional) Specifies whether this recipient receives inventory email notifications.

user_name* | *user_id

(Required) Specifies the email recipient for whom you are modifying settings.

Description

This command modifies the settings that are established for an email recipient. Standard rules regarding names apply; therefore, it is not possible to change a name to **emailusern**, where *n* is a number.

Note: Before the **usertype** parameter can be set to support, the **-warning** and **-info** flags must be set to **off**.

Remember: When considering e-mail addresses:

- Alphanumeric characters and additionally underscore (**_**), at symbol (**@**), and dot (**.**) characters are permitted.
- There must be exactly one **@** character in the string, and the **@** characters must not start or end the string.
- A plus (**+**) character is permitted before the **@** character.

An invocation example

The following example modifies email settings for email recipient **manager2008**:

```
chemailuser -usertype local manager2008
```

The resulting output:

```
No feedback
```

An invocation example

The following example modifies email settings:

```
chemailuser -address fred@gmail.com -name Fred
```

The resulting output:

```
No feedback
```

mkserver

Use the **mkserver** command to create an email server object that describes a remote Simple Mail Transfer Protocol (SMTP) email server.

mkserver

Use the **mkserver** command to add a recipient of email event and inventory notifications to the email event notification facility. Add up to twelve recipients (one recipient at a time).

mkserver

Use the **mkserver** command to create a Simple Network Management Protocol (SNMP) server to receive notifications.

rserver

Use the **rserver** command to delete the specified email server object.

rserver

Use the **rserver** command to remove a previously defined email recipient from the system.

rserver

Use the **rserver** command to delete the specified Simple Network Management Protocol (SNMP) server.

sendinventoryemail

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

setemail (Discontinued)

Attention: The **setemail** command is discontinued. E-mail notification can be configured using the following commands: **mkserver**, **chemailserver**, **rserver**, **chemail**, and **lserver**.

startemail

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

testemail

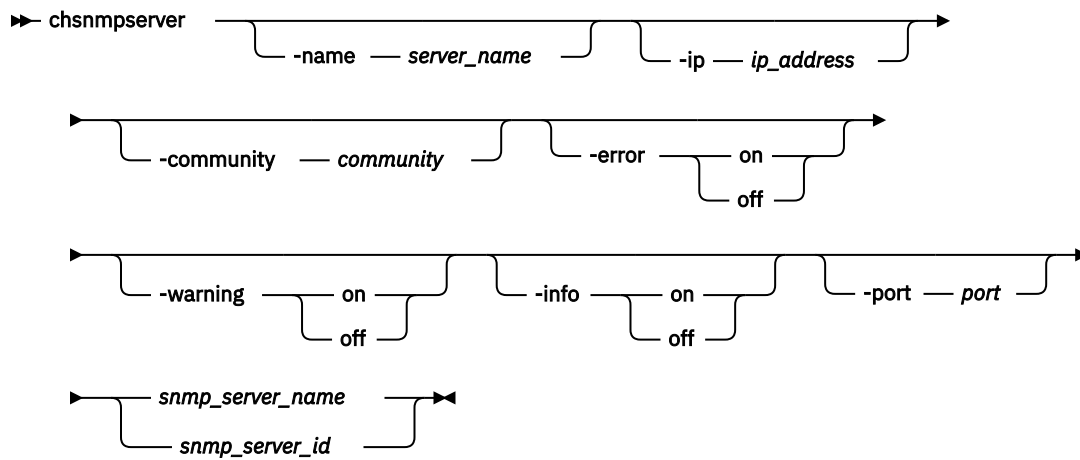

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

chsnmpserver

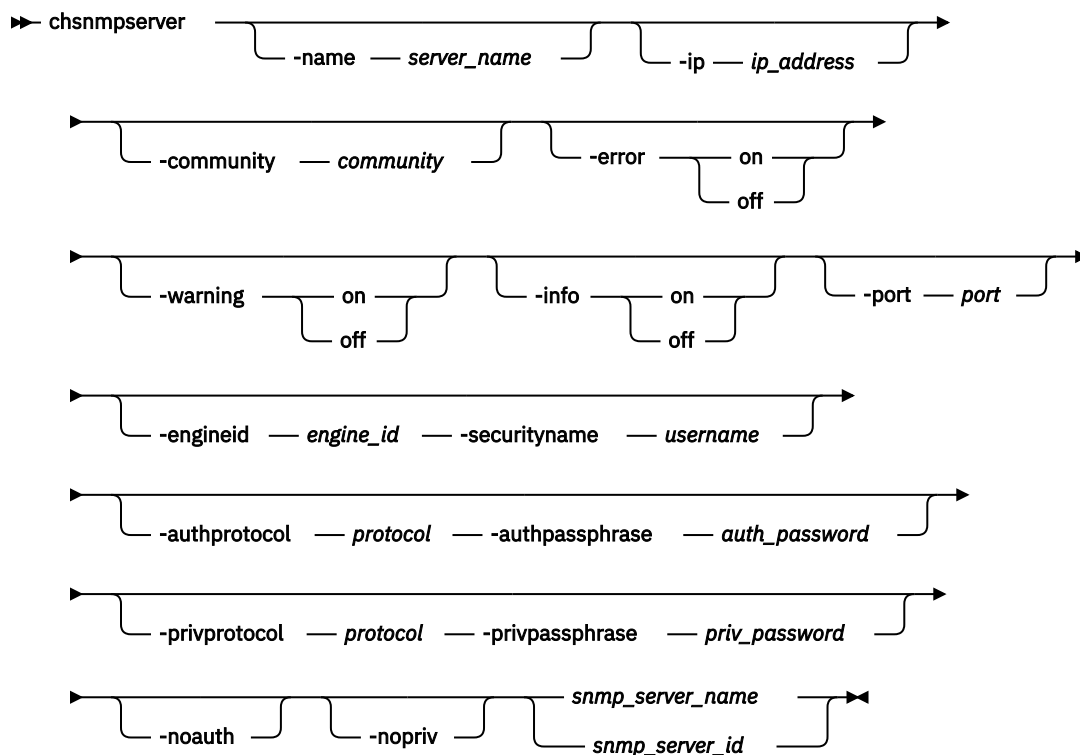

Use the **chsnmpserver** command to modify the parameters of an existing SNMP server.

Syntax

This diagram is for SNMPv2.

This diagram is for SNMPv3.

Parameters

-name server_name

(Optional) Specifies a name to assign to the SNMP server. The name must be unique. When specifying a server name, *snmp* is a reserved word.

-ip ip_address

(Optional) Specifies an IP address to assign to the SNMP server. This must be a valid IPv4 or IPv6 address.

-community community

(Optional) Specifies the community name for the SNMP server.

-error on | off

(Optional) Specifies whether the server receives error notifications. Set to *on*, error notifications are sent to the SNMP server. Set to *off*, error notifications are not sent to the SNMP server.

-warning on | off

(Optional) Specifies whether the server receives warning notifications. Set to **on**, warning notifications are sent to the SNMP server. Set to **off**, warning notifications are not sent to the SNMP server.

-info on | off

(Optional) Specifies whether the server receives information notifications. Set to **on**, information notifications are sent to the SNMP server. Set to **off**, information notifications are not sent to the SNMP server.

-port port

(Optional) Specifies the remote port number for the SNMP server. This must be a value of 1 - 65535.

-engineid engine_id

(Optional) Specifies the engine ID for the SNMPv3 server. This value has a max of 32 bytes. You must specify **-securityname** with this parameter.

-securityname username

(Optional) Specifies the security name for the SNMPv3 server. This value has a max of 32 characters. You must specify **-engineid** with this parameter.

-authprotocol protocol

(Optional) Specifies the authentication protocol for the SNMPv3 server. Available values are **sha** or **md5**. You must specify **-authpassphrase** with this parameter.

-authpassphrase auth_password

(Optional) Specifies the authentication password for the SNMPv3 server. This value must be in the range of 8 - 255 characters. You must specify **-authprotocol** with this parameter.

-privprotocol protocol

(Optional) Specifies the privacy protocol for the SNMPv3 server. Available values are **aes** or **des**. You must specify **-privpassphrase** with this parameter.

-privpassphrase priv_password

(Optional) Specifies the privacy password for the SNMPv3 server. This value must be in the range of 8 - 255 characters. You must specify **-privprotocol** with this parameter.

-noauth

(Optional) Removes all authentication and privacy settings from the SNMPv3 server. It is not possible to have privacy settings without authentication.

-nopriv

(Optional) Removes the privacy protocol and passphrase settings from the SNMPv3 server.

snmp_server_name | snmp_server_id

(Required) Specifies the name or ID of the server to be modified.

Description

Use this command to change the settings of an existing SNMP server. You must specify either the current name of the server or the ID returned at creation time. Use the **lssnmpserver** command to obtain this ID.

To switch from an SNMPv3 server to an SNMPv2 server, you must specify the **-community** parameter.

An invocation example to change the name of snmpserver 0

```
chsnmpserver -name newserver 0
```

The resulting output:

```
No feedback
```

An invocation example to change the privacy password for snmpserver 0

```
chsnmpserver -privpassphrase new_priv_pw 0
```

The resulting output:

No feedback

mkserver

Use the **mkserver** command to create an email server object that describes a remote Simple Mail Transfer Protocol (SMTP) email server.

mkuser

Use the **mkuser** command to add a recipient of email event and inventory notifications to the email event notification facility. Add up to twelve recipients (one recipient at a time).

mksnmpserver

Use the **mksnmpserver** command to create a Simple Network Management Protocol (SNMP) server to receive notifications.

rserver

Use the **rserver** command to delete the specified email server object.

ruser

Use the **ruser** command to remove a previously defined email recipient from the system.

rserver

Use the **rserver** command to delete the specified Simple Network Management Protocol (SNMP) server.

sendinventoryemail

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

setemail (Discontinued)

Attention: The **setemail** command is discontinued. E-mail notification can be configured using the following commands: **mkserver**, **chemailserver**, **rserver**, **chemail**, and **lserver**.

startemail

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

testemail

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

lsmailserver

Use the **lsmailserver** command to display a concise list or a detailed view of email servers that are configured on the system.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

email_server_name / email_server_id

(Optional) Specifies the name or ID of an existing email server that must be listed.

Description

Use this command to display a concise list or a detailed view of email servers that are configured on the system.

This table provides the attribute values that can be displayed as output view data.

Table 75. <i>lsmailserver</i> output	
Attribute	Description
id	Indicates the ID of the email server.
name	Indicates the name of the email server.
IP_address	Indicates the IP address of the email server.
port	Indicates the port of the email server.
status	Indicates the state of the email server as reported by the last periodic health check or email send attempt. The possible values are: <ul style="list-style-type: none">• untried (default)• failed• failed_temporary• active

A concise invocation example

```
lserver -delim :
```

The concise resulting output:

```
id:name:IP_address:port:status
0:emailserver0:192.135.60.3:25:active
1:emailserver1:192.135.60.4:25:active
2:emailserver2:192.135.60.5:25:active
```

A detailed invocation example

```
lserver email0
```

The detailed resulting output:

```
id 0
name emailserver0
IP_address 192.135.60.3
port 25
status active
```

A concise invocation example

```
lserver
```

The concise resulting output:

```
id name IP_address port status
0 mail00 9.174.157.177 25 untried
1 mail02 9.174.157.9 25 failed_temporary
2 mail04 25 active
```

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

testemail

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

lsemailuser

Use the **lsemailuser** command to generate a report that lists the email event notification settings for all email recipients, an individual email recipient, or a specified type (local or support) of email recipient.

Syntax

Parameters

-type support | local

(Optional) Specifies the types of email recipients you want to view, either customer-based or support-based as determined by the following definitions:

support

Address of the support organization that provides vendor support.

local

All other addresses.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space that is separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, a colon separates all items of data in a concise view; the spacing of columns does not occur. In a detailed view, the data is separated from its header by a colon.

user_name / user_id

(Optional) Specifies the user ID or user name of the email event recipient for whom you want to see the email notification settings.

Description

When you issue this command, a report is displayed that lists the email event notification settings for all email recipients, an individual email recipient, or a specified type (local or support) of email recipient. The concise and detailed views report the same information.

A concise invocation example listing information for all email recipients by using the email event notification facility

```
lsemailuser -delim :
```

The resulting output:

```
id:name:address:user_type:error:warning:info:inventory
1:Support:callhome1@de.ibm.com:support:on:off:off:off
2:Fred:fred_house@my_company.co.uk:local:on:on:on:off
3:Log:our_log@my_company.co.uk:local:on:on:on:on
```

Use the **rmemailserver** command to delete the specified email server object.

rmemailuser

Use the **rmemailuser** command to remove a previously defined email recipient from the system.

rmsnmpserver

Use the **rmsnmpserver** command to delete the specified Simple Network Management Protocol (SNMP) server.

sendinventoryemail

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

setemail (Discontinued)

Attention: The **setemail** command is discontinued. E-mail notification can be configured using the following commands: **mkemailserver**, **chemailserver**, **rmemailserver**, **chemail**, and **lsemailserver**.

startemail

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

testemail

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

lssnmpserver

Use the **lssnmpserver** command to return a concise list or a detailed view of SNMP servers that are configured on the system.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

snmp_server_name / snmp_server_id

(Optional) Specifies the name or ID of an existing SNMP server that must be listed.

Description

Use this command to display a concise list or a detailed view of SNMP servers that are configured on the system. This table describes possible outputs.

Table 76. **lssnmpserver** output

Attribute	Value
id	Indicates the ID of the SNMP server.
name	Indicates the name of the SNMP server.
IP_address	Indicates the IP address of the SNMP server.
error	Indicates whether the server receives error notifications. The values are on or off.
warning	Indicates whether the server receives warning notifications. The values are on or off.
info	Indicates whether the server receives information notifications. The values are on or off.
port	Indicates the remote port number for the SNMP server. This value is in the range of 1 - 65535.
community	Indicates the community name for the SNMPv2 server. This value is blank for SNMPv3 servers.
version	Indicates the SNMP server version. The values are 2 or 3.
securitylevel	Indicates the SNMPv3 security level. The values are blank, no_auth_no_priv, auth_no_priv, or auth_priv.
engineid	Indicates the SNMPv3 server engine ID. The values are blank or a 32-byte character string with the leading 0x removed.
securityname	Indicates the SNMPv3 server security name. The values are blank or a max 32-character string.
authprotocol	Indicates the SNMPv3 server authentication protocol. The values are blank, sha, or md5.
authpassphrase	Indicates the SNMPv3 server authentication password. The values are blank or auth_password.
privprotocol	Indicates the SNMPv3 server privacy protocol. The values are blank, aes, or des.
privpassphrase	Indicates the SNMPv3 server privacy password. The values are blank or priv_password.

A concise invocation example

```
lssnmpserver
```

The concise resulting output:

```
id name IP_address error warning info port community version securitylevel
0 snmp0 9.174.157.8 on on on 162 public 2
1 snmp1 9.174.157.9 on on on 162 public 3 authPriv
```

A detailed invocation example for an SNMPv2 server

```
lssnmpserver 0
```

The detailed resulting output:

```
id 0
name snmp0
IP_address 9.174.157.8
error on
warning on
info on
port 162
community public
version 2
securitylevel
engineid
securityname
authprotocol
authpassphrase
privprotocol
privpassphrase
```

A detailed invocation example for an SNMPv3 server

```
lssnmpserver 1
```

The detailed resulting output:

```
id 1
name snmp1
IP_address 9.174.157.9
error on
warning on
info on
port 162
community
version 3
securitylevel authPriv
engineid 80000002045370656356000000C021800002
securityname mcr-tb5-cluster-29
authprotocol sha
authpassphrase cluster_auth_pw
privprotocol aes
privpassphrase cluster_priv_pw
```

rmemailserver

Use the **rmemailserver** command to delete the specified email server object.

rmemailuser

Use the **rmemailuser** command to remove a previously defined email recipient from the system.

rmsnmpserver

Use the **rmsnmpserver** command to delete the specified Simple Network Management Protocol (SNMP) server.

sendinventoryemail

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

setemail (Discontinued)

Attention: The **setemail** command is discontinued. E-mail notification can be configured using the following commands: **mkemailserver**, **chemailserver**, **rmemailserver**, **chemail**, and **lsemailserver**.

startemail

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

testemail

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

mkemailserver

Use the **mkemailserver** command to create an email server object that describes a remote Simple Mail Transfer Protocol (SMTP) email server.

Syntax

```
➔ mkemailserver -name server_name -ip ip_address ➔
               -port port ➔
```

Parameters

-name server_name

(Optional) Specifies a unique name to assign to the email server object. The name must be a 1-through 63-character string, and cannot start with a hyphen or number. If a name is not specified, then a system default of `emailservern` is applied, where *n* is the object ID. When specifying a server name, `emailserver` is a reserved word.

-ip *ip_address*

(Required) Specifies the IP address of a remote email server. This must be a valid IPv4 or IPv6 address. IPv6 addresses can be zero compressed.

-port *port*

(Optional) Specifies the port number for the email server. This must be a value of 1 - 65535. The default value is 25.

Description

This command creates an email server object that represents the SMTP server. The SAN Volume Controller uses the email server to send event notification and inventory emails to email users. It can transmit any combination of error, warning, and informational notification types.

The SAN Volume Controller supports up to six email servers to provide redundant access to the external email network. The email servers are used in turn until the email is successfully sent from the SAN Volume Controller. The attempt is successful when the SAN Volume Controller gets a positive acknowledgement from an email server that the email has been received by the server.

An invocation example

```
mkemailserver -ip 2.2.2.2 -port 78
```

The resulting output:

```
Emailserver id [2] successfully created
```

Related referencechemail

Use the **chemail** command to set or modify contact information for email event notifications. At least one of the parameters must be specified to modify settings.

chemailserver

Use the **chemailuser** command to modify the settings that are defined for an email recipient.

chsnmpserver

Use the **chsnmpserver** command to modify the parameters of an existing SNMP server.

lserver

Use the **lserver** command to display a concise list or a detailed view of email servers that are configured on the system.

lserveruser

Use the **lserveruser** command to generate a report that lists the email event notification settings for all email recipients, an individual email recipient, or a specified type (local or support) of email recipient.

lserver

Use the **lserver** command to return a concise list or a detailed view of SNMP servers that are configured on the system.

mkemailuser

Use the **mkemailuser** command to add a recipient of email event and inventory notifications to the email event notification facility. Add up to twelve recipients (one recipient at a time).

mksnmpserver

Use the **mksnmpserver** command to create a Simple Network Management Protocol (SNMP) server to receive notifications.

rserver

Use the **rserver** command to delete the specified email server object.

rserveruser

Use the **rmemailuser** command to remove a previously defined email recipient from the system.

rmsnmpserver

Use the **rmsnmpserver** command to delete the specified Simple Network Management Protocol (SNMP) server.

sendinventoryemail

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

setemail (Discontinued)

Attention: The **setemail** command is discontinued. E-mail notification can be configured using the following commands: **mkemailserver**, **chemailserver**, **rmemailserver**, **chemail**, and **lsemailserver**.

startemail

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

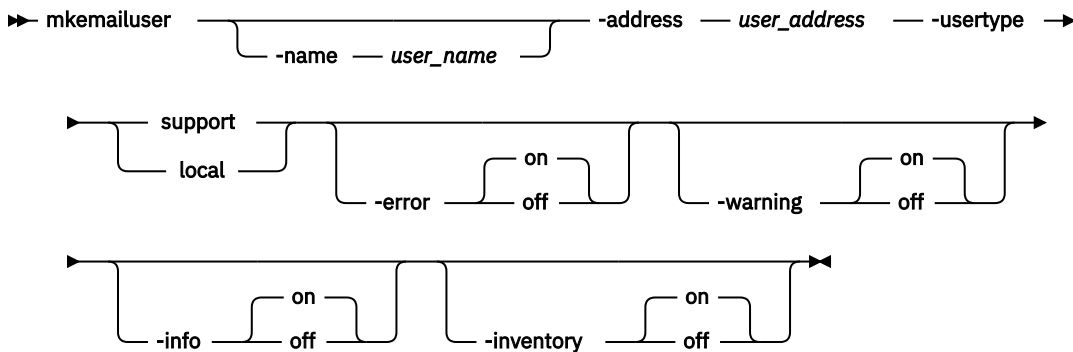

testemail

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

mkemailuser

Use the **mkemailuser** command to add a recipient of email event and inventory notifications to the email event notification facility. Add up to twelve recipients (one recipient at a time).

Syntax

Parameters

-name user_name

(Optional) Specifies the name of the person who is the recipient of email event notifications. The *user_name* value must be unique, must not contain spaces, and must not contain only numbers. If you do not specify a user name, the system automatically assigns a user name in the format of emailuser*n*, where *n* is a number beginning with 0 (emailuser0, emailuser1, and so on).

The name emailuser*n*, where *n* is a number, is reserved and cannot be used as one of your user names.

-address user_address

(Required) Specifies the email address of the person receiving the email event or inventory notifications, or both. The *user_address* value must be unique.

-usertype support | local

(Required) Specifies the type of user, either local or support, based on the following guidelines:

support

The recipient is your product support organization, using a default value (an auto-populated email address). This setting is used with the Call Home feature. For any other use case, contact your product support organization for direction.

local

All other recipients other than your product support organization. Select the `local` usertype unless otherwise instructed by your product support organization.

-error on | off

(Optional) Specifies whether the recipient receives error-type event notifications. Set to `on`, error-type event notifications are sent to the email recipient. Set to `off`, error-type event notifications are not sent to the recipient. The default value is `on`.

-warning on | off

(Optional) Specifies whether the recipient receives warning-type event notifications. Set to `on`, warning-type event notifications are sent to the email recipient. Set to `off`, warning-type event notifications are not sent to the recipient. The default value is `on`.

-info on | off

(Optional) Specifies whether the recipient receives informational event notifications. Set to `on`, informational event notifications are sent to the email recipient. Set to `off`, informational event notifications are not sent to the recipient. The default value is `on`.

-inventory on | off

(Optional) Specifies whether this recipient receives inventory email notifications. The default value is `off`.

Description

This command adds email recipients to the email event and inventory notification facility. You can add up to twelve recipients, one recipient at a time. When an email user is added, if a user name is not specified, a default name is allocated by the system. This default name has the form of `emailuser1`, `emailuser2`, and so on. Email notification starts when you process the **startemail** command.

Note: Before you can set the **usertype** parameter to `support`, turn the **-warning** and **-info** flags off.

Remember: When considering e-mail addresses:

- Alphanumeric characters and additionally underscore (`_`), at symbol (`@`), and dot (`.`) characters are permitted.
- There must be exactly one `@` character in the string, and the `@` characters must not start or end the string.
- A plus (`+`) character is permitted before the `@` character.

An invocation example

```
mkemailuser -address manager2008@ibm.com -error on -usertype local
```

The resulting output:

```
email user, id [2], successfully created
```

Related referencechemail

Use the **chemail** command to set or modify contact information for email event notifications. At least one of the parameters must be specified to modify settings.

chemailserver

rmemailuser

Use the **rmemailuser** command to remove a previously defined email recipient from the system.

rmsnmpserver

Use the **rmsnmpserver** command to delete the specified Simple Network Management Protocol (SNMP)server.

sendinventoryemail

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

setemail (Discontinued)

Attention: The **setemail** command is discontinued. E-mail notification can be configured using the following commands: **mkemailserver**, **chemailserver**, **rmemailserver**, **chemail**, and **lsemailserver**.

startemail

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

testemail

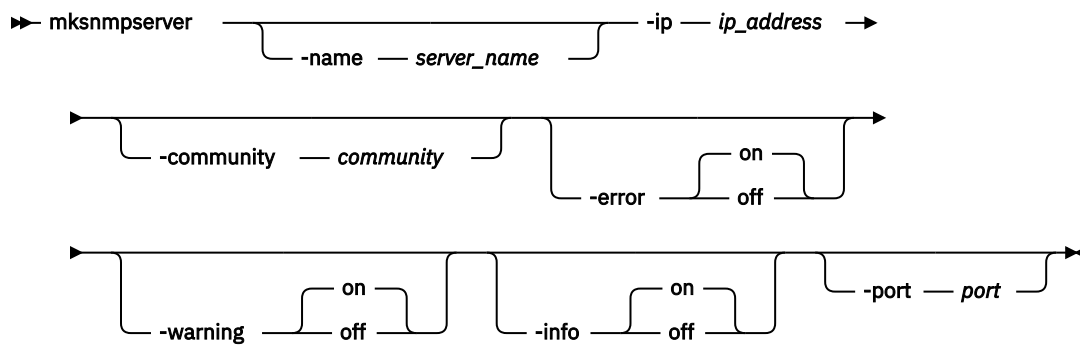

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

mksnmpserver

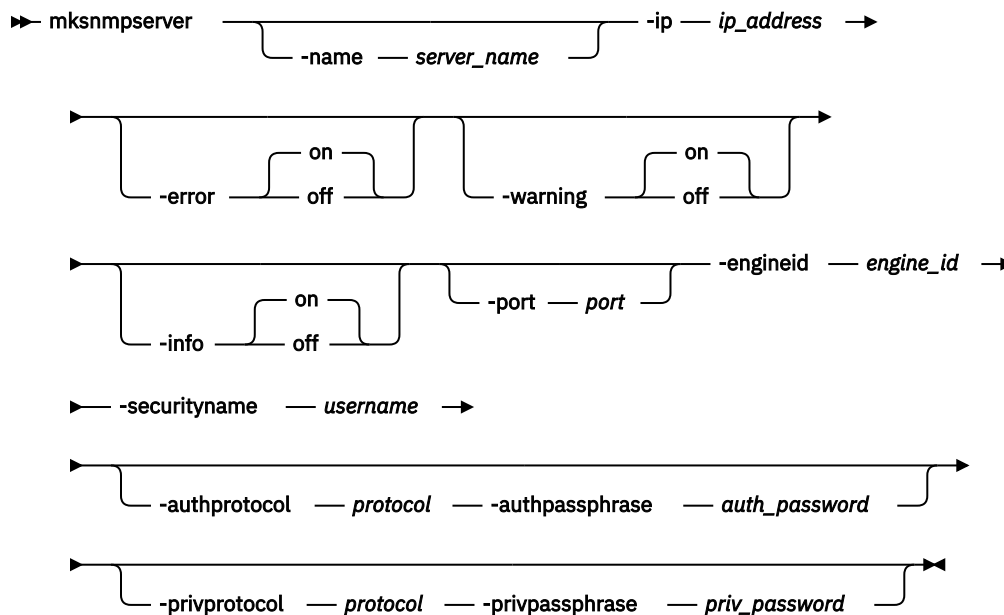

Use the **mksnmpserver** command to create a Simple Network Management Protocol (SNMP) server to receive notifications.

Syntax

This diagram is for SNMPv2.

This diagram is for SNMPv3.

Parameters

-name *server_name*

(Optional) Specifies a unique name to assign to the SNMP server. If a name is not specified, then a system default of `snmpn` is applied, where *n* is the ID of the server. When specifying a server name, `snmp` is a reserved word.

-ip *ip_address*

(Required) Specifies the IP address of the SNMP server. This must be a valid IPv4 or IPv6 address.

-community *community*

(Optional) Specifies the community name for the SNMPv2 server. If you do not specify a community name, then the default name of `public` is used.

-error on | off

(Optional) Specifies whether the server receives error notifications. Set to `on`, error notifications are sent to the SNMP server. Set to `off`, error notifications are not sent to the SNMP server. The default value is `on`.

-warning on | off

(Optional) Specifies whether the server receives warning notifications. Set to `on`, warning notifications are sent to the SNMP server. Set to `off`, warning notifications are not sent to the SNMP server. The default value is `on`.

-info on | off

(Optional) Specifies whether the server receives information notifications. Set to **on**, information notifications are sent to the SNMP server. Set to **off**, information notifications are not sent to the SNMP server. The default value is **on**.

-port port

(Optional) Specifies the remote port number for the SNMP server. This must be a value of 1 - 65535. The default value is 162.

-engineid engine_id

(Required) Specifies the engine ID for the SNMPv3 server. This value has a max of 32 bytes. You must specify **-securityname** with this parameter.

-securityname username

(Required) Specifies the security name for the SNMPv3 server. This value has a max of 32 characters. You must specify **-engineid** with this parameter.

-authprotocol protocol

(Optional) Specifies the authentication protocol for the SNMPv3 server. Valid values are **sha** or **md5**. You must specify **-authpassphrase** with this parameter.

-authpassphrase auth_password

(Optional) Specifies the authentication password for the SNMPv3 server. This value must be in the range of 8 - 255 characters. You must specify **-authprotocol** with this parameter.

-privprotocol protocol

(Optional) Specifies the privacy protocol for the SNMPv3 server. Valid values are **aes** or **des**. You must specify **-privpassphrase** with this parameter.

-privpassphrase priv_password

(Optional) Specifies the privacy password for the SNMPv3 server. This value must be in the range of 8 - 255 characters. You must specify **-privprotocol** with this parameter.

Description

This command creates an SNMPv2 or SNMPv3 server to receive notifications.

The system supports a maximum of 6 SNMP servers.

An invocation example to create an SNMPv2 server

```
mksnmpserver -ip 2.2.2.2 -port 78
```

The resulting output:

```
SNMP Server id [2] successfully created
```

An invocation example to create an SNMPv3 server with no authentication or privacy values

```
mksnmpserver -ip 9.174.157.8 -engineid 0x80000002045370656356000000C021800002 -securityname mcr-tb5-cluster-29
```

The resulting output:

```
SNMP Server id [3] successfully created
```

An invocation example to create an SNMPv3 server with authentication and privacy values

```
mksnmpserver -ip 9.174.157.8 -engineid 0x80000002045370656356000000C021800002 -securityname mcr-tb5-cluster-29 -authprotocol sha -authpassphrase cluster_auth_pw -privprotocol aes -privpassphrase cluster_priv_pw
```

The resulting output:

```
SNMP Server id [4] successfully created
```

luser

Use the **luser** command to generate a report that lists the email event notification settings for all email recipients, an individual email recipient, or a specified type (local or support) of email recipient.

snmpserver

Use the **snmpserver** command to return a concise list or a detailed view of SNMP servers that are configured on the system.

mkserver

Use the **mkserver** command to create an email server object that describes a remote Simple Mail Transfer Protocol (SMTP) email server.

mkuser

Use the **mkuser** command to add a recipient of email event and inventory notifications to the email event notification facility. Add up to twelve recipients (one recipient at a time).

mksnmpserver

Use the **mksnmpserver** command to create a Simple Network Management Protocol (SNMP) server to receive notifications.

rmserver

Use the **rmserver** command to delete the specified email server object.

rmuser

Use the **rmuser** command to remove a previously defined email recipient from the system.

sendinventoryemail

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

setemail (Discontinued)

Attention: The **setemail** command is discontinued. E-mail notification can be configured using the following commands: **mkserver**, **chserver**, **rmserver**, **chuser**, and **lserver**.

startemail

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

testemail

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

sendinventoryemail

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

Syntax

►► sendinventoryemail ◄◄

Parameters

There are no parameters for this command.

Description

This command sends an inventory email notification to all email recipients who are enabled to receive inventory email notifications. This command fails if the **startemail** command has not been processed and at least one email recipient using the email event and inventory notification facility has not been set up to receive inventory email notifications. This command also fails if the email infrastructure has not been set up.

An invocation example

In the following example, you send an inventory email notification to all email recipients who are enabled to receive them:

```
sendinventoryemail
```

The resulting output:

```
No feedback
```

[rmemailserver](#)

Use the **rmemailserver** command to delete the specified email server object.

[rmemailuser](#)

Use the **rmemailuser** command to remove a previously defined email recipient from the system.

[rmsnmpserver](#)

Use the **rmsnmpserver** command to delete the specified Simple Network Management Protocol (SNMP) server.

[sendinventoryemail](#)

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

[startemail](#)

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

[stopemail](#)

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

[testemail](#)

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

startemail

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

Syntax

➤ startemail ➤

Parameters

There are no parameters for this command.

Description

This command enables the email event notification service. No emails are sent to users until the **startemail** command has been run and at least one user has been defined to the system.

Note: This command fails if the **chemail** command has not been used to provide adequate configuration details. The following **chemail** parameters must be specified:

- **reply**
- **contact**
- **primary**
- **location**

An invocation example to start the email error notification service

```
startemail
```

The resulting output:

```
No feedback
```

Related reference

[chemail](#)

Use the **chemail** command to set or modify contact information for email event notifications. At least one of the parameters must be specified to modify settings.

chemailserver

Use the **chemailserver** command to modify the parameters of an existing email server object.

chemailuser

Use the **chemailuser** command to modify the settings that are defined for an email recipient.

chsnmpserver

Use the **chsnmpserver** command to modify the parameters of an existing SNMP server.

lserver

Use the **lserver** command to display a concise list or a detailed view of email servers that are configured on the system.

luser

Use the **luser** command to generate a report that lists the email event notification settings for all email recipients, an individual email recipient, or a specified type (local or support) of email recipient.

ssnmpserver

Use the **ssnmpserver** command to return a concise list or a detailed view of SNMP servers that are configured on the system.

mkemailserver

Use the **mkemailserver** command to create an email server object that describes a remote Simple Mail Transfer Protocol (SMTP) email server.

mkemailuser

Use the **mkemailuser** command to add a recipient of email event and inventory notifications to the email event notification facility. Add up to twelve recipients (one recipient at a time).

mksnmpserver

Use the **mksnmpserver** command to create a Simple Network Management Protocol (SNMP) server to receive notifications.

rserver

Use the **rserver** command to delete the specified email server object.

ruser

Use the **ruser** command to remove a previously defined email recipient from the system.

rdsnmpserver

Use the **rdsnmpserver** command to delete the specified Simple Network Management Protocol (SNMP) server.

sendinventoryemail

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

setemail (Discontinued)

Attention: The **setemail** command is discontinued. E-mail notification can be configured using the following commands: **mkemailserver**, **chemailserver**, **rserver**, **chemail**, and **lserver**.

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

testemail

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

Syntax

➤ stopemail ➤

Parameters

There are no parameters for this command.

Description

This command stops the email error notification function. No emails are sent to users until the **startemail** command is reissued.

An invocation example to stop the email and inventory notification function

```
stopemail
```

The resulting output:

```
No feedback
```

rmemailserver

Use the **rmemailserver** command to delete the specified email server object.

rmemailuser

Use the **rmemailuser** command to remove a previously defined email recipient from the system.

rmsnmpserver

Use the **rmsnmpserver** command to delete the specified Simple Network Management Protocol (SNMP)server.

sendinventoryemail

Use the **sendinventoryemail** command to send an inventory email notification to all email recipients able to receive inventory email notifications. There are no parameters for this command.

setemail (Discontinued)

Attention: The **setemail** command is discontinued. E-mail notification can be configured using the following commands: **mkemailserver**, **chemailserver**, **rmemailserver**, **chemail**, and **lsemailserver**.

startemail

Use the **startemail** command to activate the email and inventory notification function. There are no parameters for this command.

testemail

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

testemail

Use the **testemail** command to send an email notification to one user or all users of the email notification function to verify correct operation.

Syntax

Parameters

user_id / user_name

(Required if you do not specify **-all**) Specifies the user ID or user name of the email recipient that you want to send a test email to. You cannot use this parameter with the **-all** parameter. The *userid_or_name* value must not contain spaces.

-all

(Required if you do not specify *user_name* or *user_id*) Sends a test email to all email users configured to receive notification of events of any notification type. No attempt is made to send the test email to a user who does not have any notification setting set to *on*.

Description

This command sends test emails to the specified users. The email recipient expects to receive the test email within a specified service time. If the email is not received within the expected time period, the

recipient must contact the administrator to ensure that the email settings for the user are correct. If a problem persists, check your product support information.

The email recipient uses the test email to check that the Simple Mail Transfer Protocol (SMTP) name, the IP address, the SMTP port, and the user address are valid.

An invocation example that sends a test email to user ID `manager2008`

```
testemail manager2008
```

The resulting output

```
No feedback
```

stopemail

Use the **stopemail** command to stop the email and inventory notification function. There are no parameters for this command.

Chapter 12. Enclosure commands

Use the enclosure commands to manage enclosures and their properties.

addcontrolenclosure

Use the **addcontrolenclosure** command to add control enclosures to the system.

Syntax

```
➤➤ addcontrolenclosure  — -iogrp — io_grp_id_or_name  — -sernum ➡
```

➡ *enclosure_serial_number*

```
— -site — site_name —
```

```
— site_id —
```

Parameters

-iogrp *io_grp_id_or_name*

The I/O group in which you want to put the control enclosure.

-sernum *enclosure_serial_number*

The serial number of the control enclosure you want to add.

-site *site_name* / *site_id*

(Optional) Specifies the numeric site ID or site name of the new control enclosure. (The site ID can be set to a value of 1 or 2 only.)

Description

Use this command to add a control enclosure to the system.

Compressed or thin-deduplicated volumes can be added only to systems in which all nodes support deduplicated volumes. You can add only nodes that support deduplicated volumes to a system that contains compressed or thin deduplicated volumes. Nodes can be added only to a system that contains compressed or thin deduplicated volumes if that new node can support the amount of memory that is allocated for data deduplication in the target I/O group.

An invocation example

```
addcontrolenclosure -iogrp 0 -sernum 2361443
```

The following output is displayed:

```
Enclosure containing Node, id [x], successfully added
```

An invocation example

```
addcontrolenclosure -iogrp 1 -sernum 1234567 -site site2
```

The following output is displayed:

```
Enclosure, Node id [2], successfully added
```

The **chenclosurevpd** command is deprecated. Use the **chvpd** command instead.

[lsenclosure](#)

Use the **lsenclosure** command to view a summary of the enclosures.

[lsenclosurebattery](#)

Use the **lsenclosurebattery** command to display information about the batteries. The batteries are located in the node canisters.

[lscontrolenclosurecandidate \(Storwize family products only\)](#)

Use the **lscontrolenclosurecandidate** command to display a list of all control enclosures you can add to the current system.

[lsenclosurecanister](#)

Use the **lsenclosurecanister** command to view a detailed status for each canister in an enclosure.

[lsenclosurechassis](#)

Use the **lsenclosurechassis** command to provide a description of the chassis-specific enclosure properties, including its location within the chassis.

[lsenclosuredisplaypanel](#)

Use the **lsenclosuredisplaypanel** command to display information about the display panel in an enclosure.

[lsenclosurefanmodule](#)

Use the **lsenclosurefanmodule** command to report the status of each fan module and the contained fans in an enclosure.

[lsenclosurepsu](#)

Use the **lsenclosurepsu** command to view information about each power-supply unit (PSU) in the enclosure.

[lsenclosuresem](#)

Use the **lsenclosuresem** command to display the status (or any pertinent data) about secondary expander modules (SEM) in a 5U92 system.

[lsenclosureslot](#)

Use the **lsenclosureslot** command to view information about each drive slot in the enclosure.

[lsenclosurestats](#)

Use the **lsenclosurestats** command to display the most recent values (averaged) of all enclosure statistics. It can also display a history of those values for any subset of the available statistics.

[lssasfabric](#)

Use the **lssasfabric** command to see which canisters are visible to a node, and the order of these canisters.

[resetleds](#)

Use the **resetleds** command to simultaneously switch off all light-emitting diodes (LEDs) in the system, including node battery LEDs.

[triggerenclosedump](#)

Use the **triggerenclosedump** command to force the specified enclosure or enclosures to dump data.

chenclosure

Use the **chenclosure** command to modify enclosure properties.

Syntax

Parameters

Note: Optional parameters are mutually exclusive. Exactly one of the optional parameters must be set.

-identify yes / no

(Optional) Causes the identify LED start or stop flashing.

-managed yes/no

(Optional) Changes the enclosure to a managed or unmanaged enclosure.

Note: If `chenclosure -managed yes` is run on an enclosure that contains compressed drives, it causes all compressed drives with a state of unused in the enclosure to perform a format. The format must complete before the drives are available for use.

-id enclosure_id

(Optional) Changes the enclosure ID after you replace the enclosure, and enables you to control what is on the front panel.

enclosure_id

(Required) Specifies the enclosure that you want to modify.

Description

Use this command to modify enclosure properties.

An invocation example to change the enclosure ID from 7 to 4

```
chenclosure -id 4 7
```

The resulting output:

```
No feedback
```

An invocation example to change enclosure 1 to unmanaged

```
chenclosure -managed no 1
```

The resulting output:

```
No feedback
```

An invocation example to make the identify LED on enclosure 1 stop flashing

```
chenclosure -identify no 1
```

The resulting output:

```
No feedback
```

triggerenclosedump

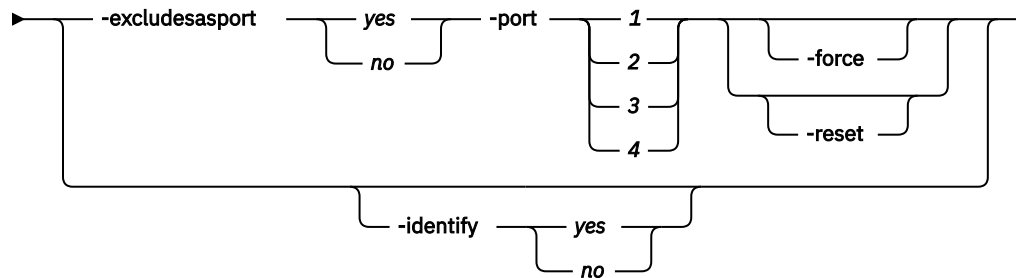

Use the **triggerenclosedump** command to force the specified enclosure or enclosures to dump data.

chenclosurecanister

Use the **chenclosurecanister** command to modify the properties of an enclosure canister.

Syntax

►► chenclosurecanister →

► -canister — canister_id — enclosure_id ►►

Note: Exactly one of the optional parameters must be set.

1. The **-port** and **-excludesasport** parameters must be specified together.
2. Exactly one of the optional parameters must be set.

Parameters

Note: Optional parameters are mutually exclusive.

-excludesasport yes / no

(Optional) Excludes or includes the specified SAS port. The **-port** and **-excludesasport** parameters must be specified together.

You can use the **-force** flag if there are dependent volumes.

Important: Using the **-force** flag might result in loss of access to your data.

Note: This parameter cannot be specified on a FlashSystem 9100 enclosure because SAS port exclude is not supported.

-force

(Optional) Forces the enclosure on the canister to be excluded.

Important: Using the **-force** parameter might result in a loss of access to your data. Use it only under the direction of your product support group or representative.

-reset

(Optional) Resets the enclosure on the canister.

Important: Using the **-reset** parameter when the partner canister is not online can lead to a loss of access to your drives (and data). Specify `lsdependentvdisks - enclosure ID -canister ID` to determine whether access to the data for one or more volumes depends on the canister being reset. Using the **-reset** parameter might result in a loss of access to your drives (and data). Use it only under the direction of your product support group or representative.

Note: This parameter cannot be specified on a FlashSystem 9100 enclosure because canister reset is not supported.

-identify yes / no

(Optional) Changes the state of fault light-emitting diode (LED) either to or from *slow_flashing*.

-port 1 / 2

(Optional) Specifies the SAS port to include or exclude. The **-port** and **-excludesasport** parameters must be specified together.

-canister canister_id

Specifies the canister to which you want to apply the change.

enclosure_id

Specifies the enclosure for which the canister is a member.

Description

This command enables you to modify the properties of an enclosure canister. You must also designate a port (by using the **-port** parameter) when this parameter is used.

An invocation example to exclude SAS port 1 on canister 2 of enclosure 1

```
chenclosurecanister -excludesasport yes -port 1 -canister 2 1
```

The resulting output:

```
No feedback
```

An invocation example to make the fault LED flash on canister 1 of enclosure 3

```
chenclosurecanister -identify yes -canister 1 3
```

The resulting output:

```
No feedback
```

Use the **chenclosuredisplaypanel** command to modify the properties for an enclosure display panel.

Syntax

➔ **chenclosuredisplaypanel** 

Parameters

-clearswap

(Optional) Specifies that the enclosure display panel swap bit be cleared.

-displaypanel sem_id

(Optional) Specifies the display panel ID to change. The value must be a number.

enclosure_id

(Required) Specifies the enclosure ID for the enclosure that contains the display panel. The value must be a number 1 - 99.

Description

This command modifies the properties for an enclosure display panel.

An invocation example

```
chenclosedisplaypanel -clearswap -displaypanel 1 3
```

The resulting output:

```
No feedback
```

lsenclosuresem

Use the **lsenclosuresem** command to display the status (or any pertinent data) about secondary expander modules (SEM) in a 5U92 system.

lsenclosureslot

Use the **lsenclosureslot** command to view information about each drive slot in the enclosure.

lsenclosurestats

Use the **lsenclosurestats** command to display the most recent values (averaged) of all enclosure statistics. It can also display a history of those values for any subset of the available statistics.

lssasfabric

Use the **lssasfabric** command to see which canisters are visible to a node, and the order of these canisters.

resetleds

Use the **resetleds** command to simultaneously switch off all light-emitting diodes (LEDs) in the system, including node battery LEDs.

triggerenclosuredump

Use the **triggerenclosuredump** command to force the specified enclosure or enclosures to dump data.

chenclosurepsu

Use the **chenclosurepsu** command to modify the properties of an enclosure power-supply unit (PSU).

Syntax

►► **chenclosurepsu**  **enclosure_id** ►◄

Parameters

-psu psu_id

Identifies the PSU in the enclosure that the command will apply to.

enclosure_id

Identifies the enclosure that the slot is a member of.

Description

This command enables you to modify the properties of an enclosure PSU.

An invocation example

```
chenclosurepsu -psu 2 2
```

The resulting output:

```
There is no output if the command is successful.
```

Use the **triggerenclosedump** command to force the specified enclosure or enclosures to dump data.

chenclosuresem

Use the **chenclosuresem** command to modify the properties of an enclosure SEM.

Syntax

➔ **chenclosuresem** 

Parameters

-clearswap

(Optional) Specifies that the enclosure SEM swap bit be cleared.

-enclosuresemid *sem_id*

(Optional) Specifies the enclosure SEM ID. The value must be a number 1 - 2.

enclosure_id

(Required) Specifies the enclosure ID for the enclosure that contains the SEM. The value must be a number 1 - 99.

Description

This command modifies the properties of an enclosure SEM.

An invocation example

```
chenclosuresem -clearswap -enclosuresemid 1 8
```

The resulting output:

```
No feedback
```

triggerenclosuredump

Use the **triggerenclosedump** command to force the specified enclosure or enclosures to dump data.

chenclosureslot

Use the **chenclosureslot** command to modify the properties of an enclosure slot.

Syntax

►► chenclosureslot →

Note:

1. Optional parameters are mutually exclusive.
2. You can only specify **-port** or **-force** when you also specify **-exclude**.
3. Exactly one of the optional parameters must be set.
4. Using **-force** has an effect on the operation of **-exclude yes**.

Parameters

-identify yes / no

(Optional) Change the state of fault light-emitting diode (LED) to or from *slow_flashing*.

-exclude yes / no

(Optional) Ensures that an enclosure slot port is excluded.

Note: This parameter cannot be specified on a FlashSystem 9100 or Storwize V7000 Gen3 enclosure because its enclosure slot ports cannot be excluded.

The following list gives details of the options you can use with this parameter:

- **-exclude yes -port port_id -slot slot_id enclosureid:** The port that you specify with *port_id* is excluded. If the current state of the port is *excluded_by_enclosure*, *excluded_by_drive*, or *excluded_by_cluster*, this command appears to have no effect. However, if the current state of the port is *online*, then that state changes to *excluded_by_cluster*. The port remains excluded until you rerun this command with *no* selected.

Attention: This command checks for dependent volumes. If issuing this command would result in losing access to data, then the command fails and an error message displayed. You can use the **-force** flag to ignore these errors, but this might result in loss of access to data.

- **-exclude no -port port_id -slot slot_id enclosureid:** The port is put into *online* state, provided there are no other reasons to exclude the port. If you issue this command when the port is *online*, then it has no effect. However, if you issue this command when the port is *excluded*, then the port state does one of the following items:
 - Change to *online* status immediately.
 - Change to *online* status after all other reasons for the port to be excluded have been removed.
- **-exclude yes / no -slot slot_id enclosureid:** If you issue this command without defining a port, the command simultaneously acts on both ports.

-port 1 / 2

(Optional) Specifies the port on the canister to be excluded. If it is not specified, **-exclude** acts on both ports.

-force

(Optional) Forces the port on the canister to be excluded.

Important: Using the **-force** parameter might result in a loss of access. Use it only under the direction of your product support information.

-slot slot_id

(Required) Specifies the slot ID. The value must be a number from 1 - 92.

The slots are numbered 1 (leftmost) to 24 (rightmost) when viewed from in front of the enclosure, in 24-slot enclosures. In 12-slot enclosures, the slots are arranged in numerical order in three rows with four slots. For example, the:

- First row contains slots 1, 2, 3, and 4 (in that order)
- Second row contains slots 5, 6, 7, and 8 (in that order)
- Third row contains slots 9, 10, 11, and 12 (in that order)

Description

These commands enable you to modify the properties of an enclosure slot.

An invocation example to turn on the identify LED on slot 7 in enclosure 1

```
chenclosureslot -identify yes -slot 7 1
```

The resulting output:

```
No feedback
```

An invocation example to force the exclusion of port 1 of slot 7 in enclosure 3

```
chenclosureslot -exclude yes -port 1 -force -slot 7 3
```

The resulting output:

```
No feedback
```

lsenclosure

Use the **lsenclosure** command to view a summary of the enclosures.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data is available to be displayed, headings are not displayed.

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (""): `lsenclosure -filtervalue id="1*"`

-filtervalue?

(Optional) Displays the valid filter attributes for the **-filtervalue** parameter:

- drive_slots
- id
- IO_group_id
- IO_group_name
- managed
- online_canisters
- online_PSUs
- product_MTM
- serial_number
- status
- total_canisters
- total_PSUs
- type

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its

own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

enclosure_id

Detailed information for the enclosure that you specify.

Description

This command displays a summary of the enclosures (including status information for canisters and power and cooling units, and other enclosure attributes). This table shows the possible outputs:

Table 77. <i>lsenclosure</i> output	
Attribute	Description
id	Indicates the ID of the enclosure.
status	Indicates whether an enclosure is visible to the SAS network: <ul style="list-style-type: none"> • online if a managed or unmanaged enclosure is visible. • offline if a managed enclosure is not visible, and other fields hold their last known values. • degraded if an enclosure is visible, but not down both strands.
type	Indicates the type of enclosure: <ul style="list-style-type: none"> • control • expansion
managed	Indicates whether the enclosure is managed: <ul style="list-style-type: none"> • yes • no
IO_group_id	Indicates the I/O group the enclosure belongs to; blank if canisters are connected to two different I/O groups.
IO_group_name	Indicates the I/O group the enclosure belongs to; blank if canisters are connected to two different I/O groups.
fault_LED	Indicates the status of the fault light-emitting diode (LED) on the enclosure: <ul style="list-style-type: none"> • on if a service action is required immediately on the enclosure or a component within the enclosure (including a canister, power unit, or non-spaced drive). • slow_flashing if battery power not sufficient to run I/O. • off if faults exist on the enclosure or its components.
identify_LED	Indicates the state of the identify LED: <ul style="list-style-type: none"> • off if the enclosure is not identified. • slow_flashing if the enclosure is being identified.
error_sequence_number	Indicates the error log number of the highest priority error for this object. This attribute is typically blank; however, if a problem exists (for example, the status has degraded), then it contains the sequence number of that error.
product_MTM	Indicates the product machine type and model.

Table 77. **lsenclosure** output (continued)

Attribute	Description
serial_number	Indicates the serial number of the enclosure. This serial number is the product serial number, which indicates the enclosure and its contents. The enclosure has its own serial number, which is embedded in the FRU_identity 11S data.
FRU_part_number	Indicates the FRU part number of the enclosure.
FRU_identity	Indicates the 11S serial number that combines the manufacturing part number and the serial number.
total_canisters	Indicates the maximum number of canisters for this enclosure type.
online_canisters	Indicates the number of canisters that are contained in this enclosure that are online.
total_PSUs	Indicates the number of power and cooling units in this enclosure.
online_PSUs	Indicates the number of power-supply units (PSUs) contained in this enclosure that are online.
drive_slots	Indicates the number of drive slots in the enclosure.
firmware_level_1	Indicates the version of the microcode image (midplane firmware version) installed on the midplane.
firmware_level_2	Indicates the version of the midplane metadata (midplane vital product data, or VPD, version) installed on the midplane.
machine_part_number	Blank.
machine_signature	Indicates a machine signature unique to the control enclosure and representing the serial number and machine part number. The format is a hyphenated string of 19 hexadecimal characters. Remember: Expansion enclosures do not have a machine signature.
ambient_temperature	Indicates the current ambient air temperature near the enclosure. The temperature value is given in degrees centigrade and is a number from -20 to 235.
interface_speed	Indicates the SAS interface speed of the enclosure (in gigabits per second, or Gbps). The values are: <ul style="list-style-type: none"> • 6 Gbps • 12 Gbps • Blank for an unknown or unsupported enclosure
total_sems	Indicates the total number of secondary expander modules (SEMs) that are in the system. The value must be a number 0 - 2.
online_sems	Indicates the total number of SEMs in the system that are online. The value must be a number 0 - 2.

A detailed invocation example

```
lsenclosure 1
```

The following detailed output is displayed:

```
id 1
status online
```

```
type control
managed no
IO_group_id 0
IO_group_name io_grp0
fault_LED off
identify_LED off
error_sequence_number
product_MTM 2072-02A
serial_number 64G005S
FRU_part_number 85Y5896
FRU_identity 11S85Y5962YHU9994G005S
total_canisters 2
online_canisters 2
total_PSUs 2
online_PSUs 2
drive_slots 12
firmware_level_1 10
firmware_level_2 F6C07926
machine_part_number 2072L2C
machine_signature 0123-4567-89AB-CDEF
ambient_temperature 30
total_fan_modules:2
online_fan_modules:2
interface_speed:6Gb
total_sems 2
online_sems 1

Use the **lsenclosuresem** command to display the status (or any pertinent data) about secondary expander modules (SEM) in a 5U92 system.

lsenclosureslot

Use the **lsenclosureslot** command to view information about each drive slot in the enclosure.

lsenclosurestats

Use the **lsenclosurestats** command to display the most recent values (averaged) of all enclosure statistics. It can also display a history of those values for any subset of the available statistics.

lssasfabric

Use the **lssasfabric** command to see which canisters are visible to a node, and the order of these canisters.

resetleds

Use the **resetleds** command to simultaneously switch off all light-emitting diodes (LEDs) in the system, including node battery LEDs.

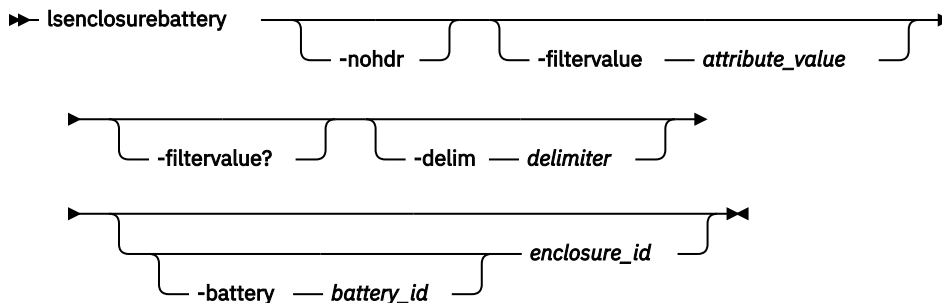

triggerenclosuredump

Use the **triggerenclosuredump** command to force the specified enclosure or enclosures to dump data.

lsenclosurebattery

Use the **lsenclosurebattery** command to display information about the batteries. The batteries are located in the node canisters.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are returned. If a capacity is specified, the units must also be included.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards when you use the CLI:

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, you must enclose the filter entry within double quotation marks (" "), as follows:

```
lsenclosurebattery -filtervalue "battery_id=1"
```

-filtervalue?

(Optional) Displays a list of valid filter attributes for the **-filtervalue** *attribute=value* parameter:

- battery_id
- charging_status
- enclosure_id
- end_of_life_warning
- percent_charged
- recondition_needed
- status

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. A detailed view provides each item of data in its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-battery battery_id

(Optional) Provides a detailed view of the specified battery. Valid only when an enclosure is specified.

enclosure_id

(Optional) Lists the batteries for the specified enclosure.

Description

This command displays information about the batteries, which are located in the node canisters. The concise view displays a line for each battery slot in every enclosure whether a battery exists for that slot or not. Batteries are not shown for expansion enclosures.

This table shows possible outputs.

Table 78. lsenclosurebattery outputs	
Attribute	Description
enclosure_id	Identifies the identity of the enclosure that contains the battery.
battery_id	Identifies the battery in the enclosure.
status	Identifies the status of the battery: <ul style="list-style-type: none"> • online indicates that the battery is present and working as usual. • degraded indicates that the battery is present but not working as usual. • offline indicates that the battery cannot be detected.
recondition_needed	Identifies that the battery needs to be reconditioned or it must start reconditioning soon. <p>Remember: If this message is permanent, there might be an error that prevents the recondition from starting.</p>

Table 78. lsenclosurebattery outputs (continued)

Attribute	Description
percent_charged	Indicates the charge of battery (in a percentage).
end_of_life_warning	Identifies the battery's end of life (with a warning noise). The values are yes and no. Important: Replace the battery.
FRU_part_number	Identifies the FRU part number of the battery.
FRU_identity	Identifies the 11S number, combining the manufacturing part number and the serial number.
firmware_level	The version of the microcode image that is installed on the battery.
error_sequence_number	Indicates the error log (or event log) number of the highest priority error for this object. This output field is typically blank. However, if there is a problem (for example, the status is degraded), then it contains the sequence number of that error event.
remaining_charge_capacity_mAh	Identifies the battery's remaining charge capacity in milliampere-hour (mAh).
full_charge_capacity_mAh	Identifies the fully charged capacity of the battery in mAh (this value diminishes as the battery ages).
compatibility_level	Identifies the battery driver software must support this level to operate with this battery - this value comes from the battery vital product data (VPD).
last_recondition_timestamp	Identifies a system timestamp, in the format YYMMDDHHMMSS, for when the last successful calibration of the gas gauge occurred, where: <ul style="list-style-type: none"> • Y is year • (The first) M is month • D is day • H is hour • (The second) M is minute • S is second
powered_on_hours	Identifies the number of hours the battery is in a powered node (not necessarily the same node).
cycle_count	Identifies the number of charge or discharge cycles that are performed on the battery.

A concise invocation example

```
lsenclosurebattery 1
```

The resulting output:

```
enclosure_id battery_id status charging_status recondition_needed percent_charged
end_of_life_warning
1             1         online idle                no                100
no
1             2         online idle                no                100                no
```

A detailed invocation example

```
lsenclosurebattery -battery 1 1
```

The resulting output:

```
enclosure_id 1
battery_id 1
status online
charging_status idle
recondition_needed no
percent_charged 100
end_of_life_warning no
FRU_part_number 31P1807
FRU_identity 11S00AR085YM30BG42R04P
firmware_level 105:1
error_sequence_number
remaining_charge_capacity_mAh 3477
full_charge_capacity_mAh 3795
compatibility_level 1
last_recondition_timestamp 140528045617
powered_on_hours 1162
cycle_count 10
```

The **chenclosurevdpd** command is deprecated. Use the **chvdpd** command instead.

[lsenclosure](#)

Use the **lsenclosure** command to view a summary of the enclosures.

[lscontrolenclosurecandidate](#) (Storwize family products only)

Use the **lscontrolenclosurecandidate** command to display a list of all control enclosures you can add to the current system.

[lsenclosurecanister](#)

Use the **lsenclosurecanister** command to view a detailed status for each canister in an enclosure.

[lsenclosurechassis](#)

Use the **lsenclosurechassis** command to provide a description of the chassis-specific enclosure properties, including its location within the chassis.

[lsenclosuredisplaypanel](#)

Use the **lsenclosuredisplaypanel** command to display information about the display panel in an enclosure.

[lsenclosurefanmodule](#)

Use the **lsenclosurefanmodule** command to report the status of each fan module and the contained fans in an enclosure.

lsenclosurepsu

Use the **lsenclosurepsu** command to view information about each power-supply unit (PSU) in the enclosure.

lsenclosuresem

Use the **lsenclosuresem** command to display the status (or any pertinent data) about secondary expander modules (SEM) in a 5U92 system.

lsenclosureslot

Use the **lsenclosureslot** command to view information about each drive slot in the enclosure.

lsenclosurestats

Use the **lsenclosurestats** command to display the most recent values (averaged) of all enclosure statistics. It can also display a history of those values for any subset of the available statistics.

lssasfabric

Use the **lssasfabric** command to see which canisters are visible to a node, and the order of these canisters.

resetleds

Use the **resetleds** command to simultaneously switch off all light-emitting diodes (LEDs) in the system, including node battery LEDs.

triggerenclosuredump

Use the **triggerenclosuredump** command to force the specified enclosure or enclosures to dump data.

lscontrolenclosurecandidate (Storwize family products only)

Use the **lscontrolenclosurecandidate** command to display a list of all control enclosures you can add to the current system.

Syntax

➤ **lscontrolenclosurecandidate** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

Table 79 on page 980 provides the possible values that are applicable to the attributes that are displayed as data in the output views.

Table 79. <i>lscontrolenclosurecandidate</i> attribute values	
Attribute	Value
serial_number	Indicates the serial number for the enclosure.
product_MTM	Indicates the MTM for the enclosure.
machine_signature	Indicates the machine signature for the enclosure.

A concise invocation example

```
lscontrolenclosurecandidate
```

The concise resulting output:

```
serial_number product_MTM machine_signature
G00F7GY      2076-624    5746-9812-B5CF-FEF9
```

Use the **lsenclosurepsu** command to view information about each power-supply unit (PSU) in the enclosure.

lsenclosuresem

Use the **lsenclosuresem** command to display the status (or any pertinent data) about secondary expander modules (SEM) in a 5U92 system.

lsenclosureslot

Use the **lsenclosureslot** command to view information about each drive slot in the enclosure.

lsenclosurestats

Use the **lsenclosurestats** command to display the most recent values (averaged) of all enclosure statistics. It can also display a history of those values for any subset of the available statistics.

lssasfabric

Use the **lssasfabric** command to see which canisters are visible to a node, and the order of these canisters.

resetleds

Use the **resetleds** command to simultaneously switch off all light-emitting diodes (LEDs) in the system, including node battery LEDs.

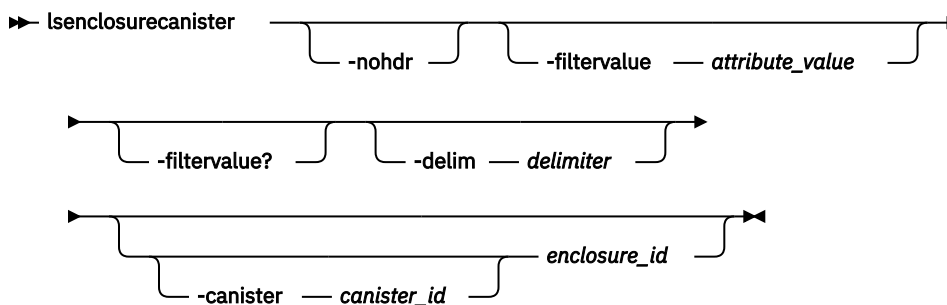

triggerenclosuredump

Use the **triggerenclosuredump** command to force the specified enclosure or enclosures to dump data.

lsenclosurecanister

Use the **lsenclosurecanister** command to view a detailed status for each canister in an enclosure.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are returned. If a capacity is specified, the units must also be included.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards when you use the CLI:

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, you must enclose the filter entry within double quotation marks (" "), as follows:

```
lsenclosurecanister -filtervalue "node_name=node*"
```

-filtervalue?

(Optional) Displays a list of valid filter attributes for the **-filtervalue** *attribute=value* parameter:

- enclosure_id
- canister_id
- node_id
- node_name
- status
- type

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-canister canister_id

(Optional) Valid only when the enclosure_id is specified. Provides a detailed view of the canister for the specified enclosure.

enclosure_id

(Optional) Lists the canisters for the specified enclosure.

Description

This command displays a detailed status for each canister in an enclosure. This table shows the possible outputs:

Table 80. <i>lsenclosurecanister</i> output	
Attribute	Description
enclosure_id	Indicates the enclosure that contains the canister.
canister_id	Indicates which of the canisters in the enclosure it is.
status	Indicates the status of the canister. The values are: <ul style="list-style-type: none">• online indicates that the canister is present and working normally.• degraded indicates that the canister is present but not working normally• offline indicates that the canister could not be detected.
type	Indicates the type of canister. The values are node or expansion.
node_id	Indicates the node that corresponds to this canister. The value is blank if the canister is not a node, or if the node is offline, or if the node is not part of the clustered system.
node_name	Indicates the node that corresponds to this canister. The value is blank if the canister is not a node, or if the node is offline, or if the node is not part of the clustered system.
temperature	Indicates the temperature of the canister in degrees centigrade.
identify_LED	Indicates the status of the identify_LED. The values are on, off, or slow-flashing.

Table 80. **lsenclosurecanister** output (continued)

Attribute	Description
fault_LED	Indicates the status of the fault_LED. The values are on, off, or slow-flashing.
SES_status	Indicates the Small Computer System Interface (SCSI) status of the connection between the device and the canister. The values are online and offline.
FRU_part_number	Indicates the field-replaceable unit (FRU) part number of the canister.
FRU_identity	Indicates the 11S number that combines the manufacturing part number and the serial number.
WWNN	Indicates the Fibre Channel (FC) worldwide node name (WWNN) of the canister (node canisters only).
temperature	Indicates the temperature of the canister (in degrees Celsius). If the temperature goes below 0, s0 is displayed. The value must be in the range 0 - 245. Remember: The temperature value is not an ambient temperature value. It is an internal temperature sensor value.
fault_LED	(0 to 245) state of the combined fault and identify light-emitting diodes (LEDs): <ul style="list-style-type: none"> • off indicates that it is not a fault • slow_flashing indicates that it is identify mode Note: When the LED is in identify mode, it conceals whether there is a fault present because it always flashes. When you remove it from identity mode, the LED becomes on or off. <ul style="list-style-type: none"> • on indicates that it is a fault
error_sequence_number	Indicates the error log number of the highest priority error for this object. This value is typically blank; however, if there is a problem (for example, the status is degraded), then the value contains the sequence number of that error.
SAS_port_1_status	Indicates whether there is damage to the cable between SAS ports: <ul style="list-style-type: none"> • online • offline • excluded (meaning logged in but cannot communicate with the canister) • degraded (meaning the SAS cable is not fully functional) • Blank (which can appear on control canisters; see lsportsas)
SAS_port_2_status	Indicates whether there is damage to the cable between SAS ports: <ul style="list-style-type: none"> • online • offline • excluded (meaning logged in but cannot communicate with the canister) • degraded (meaning the SAS cable is not fully functional) • Blank (which can appear on control canisters; see lsportsas)
firmware_level	Indicates the firmware level of the Small Computer System Interface (SCSI) Enclosure Services (SES) code, or canister firmware version, that is running on the canister.
firmware_level_2	Indicates the version of the first other microcode image (canister bootloader version) that is installed on the canister.

Table 80. **lsenclosurecanister** output (continued)

Attribute	Description
firmware_level_3	Indicates the version of the second other microcode (canister complex programmable logic device, or CPLD, version) image that is installed on the canister.
firmware_level_4	Indicates the version of the third other microcode image (canister flash configuration version) that is installed on the canister.
firmware_level_5	Indicates the version of the canister metadata (canister VPD version) that is installed on the canister.

A concise invocation example

```
lsenclosurecanister -delim :
```

The resulting output:

```
enclosure_id:canister_id:status:type:node_id:node_name
1:1:degraded:expansion:1:node1
```

A detailed invocation example

```
lsenclosurecanister -canister 1 1
```

The detailed resulting output:

```
enclosure_id 1
canister_id 1
status online
type node
node_id 1
node_name node1
FRU_part_number AAAAAAA
FRU_identity 11S1234567Y12345678901
WWNN 5005076801005F94
firmware_level XXXXXXXXXX
temperature 23
fault_LED flashing
SES_status online
error_sequence_number
SAS_port_1_status online
SAS_port_2_status online
firmware_level_2 0501
firmware_level_3 14
firmware_level_4 B69F66FF
firmware_level_5 5C2A6A44
```

Syntax

➔ **lsenclosurechassis** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

enclosure_id

(Optional) Indicates the unique enclosure identifier (a number in the range 1 - 99).

Description

This command has both a detailed and concise view. The *enclosure_id* keyword is required for the detailed view.

This table displays information about chassis-specific enclosure properties and shows possible outputs.

Table 81. lsenclosurechassis outputs	
Attribute	Description
enclosure_id	Specifies the enclosure identifier. It is a numeric character between the numbers 1 and 99.
chassis_name	Specifies the chassis name. It can be set from the CMM, and is blank or an alphanumeric string that contains up to 128 characters.
canister_1_bay	Specifies the first canister bay's enclosure position within the chassis. It is a numeric character between the numbers 0 and 254.
canister_2_bay	Specifies the second canister bay's enclosure position within the chassis. It is a numeric character between the numbers 0 and 254.
numbering scheme	Specifies the chassis numbering scheme set from the CMM. It can be a numeric character between the numbers 0 and 255.
pos_in_rack	Specifies the chassis position within the rack set from the CMM. It must be an alphanumeric 2-character string.

Table 81. **lsenclosurechassis** outputs (continued)

Attribute	Description
rack_location	Specifies the location of the rack that contains the chassis set from the CMM. It can be blank or an alphanumeric string that contains up to 128 characters.
rack_room	Specifies the room that contains the rack set from the CMM. It can be blank or an alphanumeric string that contains up to 128 characters.
chassis_mtm	Specifies the chassis machine type or model. The type or model is an alphanumeric string that contains up to 22 characters.
chassis_sn	Specifies the chassis serial number. The serial number is an alphanumeric string that contains up to 22 characters.
chassis_uuid	Specifies the chassis unique user identifier. The identifier is an alphanumeric string that contains up to 128 characters.
chassis_rack	Specifies the identifier for the rack that contains the chassis. The identifier is blank or an alphanumeric string that contains up to 128 characters.

An invocation example

```
lsenclosurechassis 1
```

The resulting output:

```
enclosure_id 1
chassis_name 25631
canister_1_bay 0
canister_2_bay 0
numbering_scheme 0
pos_in_rack 1
rack_location In the corner
rack_room D-East
chassis_mtm 2078-219
chassis_sn 64H123R
chassis_uuid 987654321
chassis_rack Rack47
```

triggerenclosuredump

Use the **triggerenclosuredump** command to force the specified enclosure or enclosures to dump data.

lsenclosuredisplaypanel

Use the **lsenclosuredisplaypanel** command to display information about the display panel in an enclosure.

Syntax

➔ **lsenclosuredisplaypanel** **-displaypanel** *displaypanel_id* **-nohdr**

➔ **-delim** *delimiter* **enclosure_id**

Parameters

-displaypanel *displaypanel_id*

(Required) Specifies the display panel ID for the display panel that is being displayed. The value must be a number.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim *delimiter*

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

enclosure_id

(Required) Specifies the enclosure ID for the enclosure data that is being displayed. The value must be a number 1 - 99.

Description

This command displays information about the display panel in an enclosure.

This table provides the attribute values that can be displayed as output view data.

Table 82. <i>lsenclosedisplaypanel</i> output	
Attribute	Description
enclosure_id	Indicates the enclosure ID for the enclosure that contains the display panel. The value must be a number 1 - 99.
displaypanel_id	Indicates the ID of the display panel that is in the enclosure. The value must be a number.
status	Indicates the display panel status for the display panel that is in the enclosure. The values are: <ul style="list-style-type: none">• online• degraded• offline
error_sequence_number	Indicates the event log sequence number for the current event that is logged against the secondary expander module (SEM). The value is blank if there is no event to log.
FRU_part_number	Indicates the FRU part number of the display panel. The value must be a 7-character numeric string.
FRU_identity	Indicates the FRU identity of the display panel. The value must be a 22-character alphanumeric string.

A concise invocation example

```
lsenclosedisplaypanel
```

The resulting output:

```
enclosure_id display_panel_id status
1             1                online
2             1                online
3             1                online
```

A detailed invocation example

```
lsenclosedisplaypanel -displaypanel 1 3
```

The resulting output:

```
enclosure_id 3
displaypanel_id 1
status online
error_sequence_number
FRU_Part_Number *****
FRU_Identity *****
```

[chenclosureslot](#)

Use the **chenclosureslot** command to modify the properties of an enclosure slot.

[satask chenclosurevpd](#) (Deprecated)

The **chenclosurevpd** command is deprecated. Use the **chvpd** command instead.

[lsenclosure](#)

Use the **lsenclosure** command to view a summary of the enclosures.

[lsenclosurebattery](#)

Use the **lsenclosurebattery** command to display information about the batteries. The batteries are located in the node canisters.

[lscontrolenclosurecandidate](#) (Storwize family products only)

Use the **lscontrolenclosurecandidate** command to display a list of all control enclosures you can add to the current system.

[lsenclosurecanister](#)

Use the **lsenclosurecanister** command to view a detailed status for each canister in an enclosure.

[lsenclosurechassis](#)

Use the **lsenclosurechassis** command to provide a description of the chassis-specific enclosure properties, including its location within the chassis.

[lsenclosurefanmodule](#)

Use the **lsenclosurefanmodule** command to report the status of each fan module and the contained fans in an enclosure.

[lsenclosurepsu](#)

Use the **lsenclosurepsu** command to view information about each power-supply unit (PSU) in the enclosure.

lsenclosuresem

Use the **lsenclosuresem** command to display the status (or any pertinent data) about secondary expander modules (SEM) in a 5U92 system.

lsenclosureslot

Use the **lsenclosureslot** command to view information about each drive slot in the enclosure.

lsenclosurestats

Use the **lsenclosurestats** command to display the most recent values (averaged) of all enclosure statistics. It can also display a history of those values for any subset of the available statistics.

lssasfabric

Use the **lssasfabric** command to see which canisters are visible to a node, and the order of these canisters.

resetleds

Use the **resetleds** command to simultaneously switch off all light-emitting diodes (LEDs) in the system, including node battery LEDs.

triggerenclosedump

Use the **triggerenclosedump** command to force the specified enclosure or enclosures to dump data.

lsenclosurefanmodule

Use the **lsenclosurefanmodule** command to report the status of each fan module and the contained fans in an enclosure.

Syntax

Parameters

-fanmodule fanmodule_id

(Optional) Specifies the ID of the fan module for which data is displayed. The possible values are 1 or 2, and any other value returns no output.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

enclosure_id

(Optional) Specifies the ID of the enclosure for which data is displayed.

Description

The command reports status for fan modules and the contained fans in an enclosure.

This table provides the possible values that are applicable to the attributes that are displayed as data in the output views.

<i>Table 83. lsenclosurefanmodule attribute values</i>	
Attribute	Value
enclosure_id	Indicates the enclosure ID of the enclosure that contains the fan module.
fan_module_id	Indicates the fan module ID of the fan module that is in the enclosure. The possible values are 1 or 2.
status	Indicates the combined status of the fan module and any contained fans. The values are: <ul style="list-style-type: none"> • online • offline • degraded
error_sequence_number	Indicates the event log sequence number of the current event that is logged against the fan module. It is blank if there is no current event.
FRU_part_number	Indicates the part number of the fan module.
FRU_identity	Indicates the FRU identity of the fan module.
fault_LED	Indicates the status of the fault light-emitting diode (LED) on the fan module: <ul style="list-style-type: none"> • on, which indicates that the LED is on • off, which indicates that the LED is off • unknown, which indicates that the LED status is unknown

An invocation example

```
lsenclosurefanmodule
```

The resulting output:

```
enclosure_id fan_module_id status
1             1             online
1             2             online
2             1             online
2             2             online
```

An invocation example

```
lsenclosurefanmodule 2
```

The resulting output:

```
enclosure_id fan_module_id status
2             1             online
2             2             online
```

An invocation example

```
lsenclosurefanmodule -fanmodule 1 1
```

The resulting output:

```
enclosure_id 1
fan_module_id 1
status online
error_sequence_number
FRU_part_number 31P1847
FRU_identity 11S31P1846YM10BG3B101N
fault_LED off
```

lssasfabric

Use the **lssasfabric** command to see which canisters are visible to a node, and the order of these canisters.

resetleds

Use the **resetleds** command to simultaneously switch off all light-emitting diodes (LEDs) in the system, including node battery LEDs.

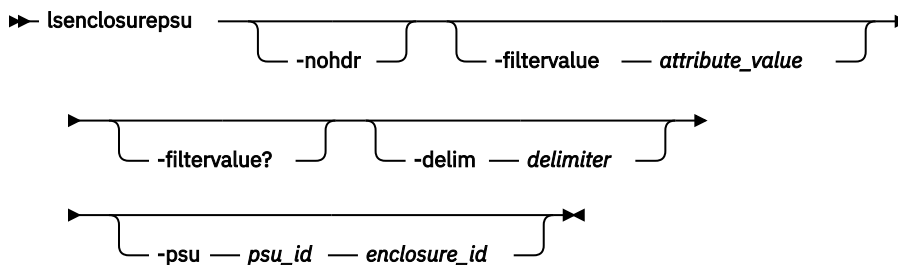

triggerenclosedump

Use the **triggerenclosedump** command to force the specified enclosure or enclosures to dump data.

lsenclosurepsu

Use the **lsenclosurepsu** command to view information about each power-supply unit (PSU) in the enclosure.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (""):

```
lsenclosurepsu -filtervalue "psu_id=1"
```

-filtervalue?

(Optional) Displays the valid filter attributes for the **-filtervalue** parameter:

- enclosure_id
- psu_id
- status

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-psu psu_id

(Optional) Valid only when the **enclosure_id** is specified. Provides a detailed view of the PSU for the specified enclosure.

enclosure_id

(Optional) Lists the PSUs for the specified enclosure.

Description

This command displays information about each power-supply unit (PSU) in the enclosure. This table shows the possible outputs:

Table 84. <i>lsenclosurepsu</i> output	
Attribute	Description
enclosure_id	Indicates the ID of the enclosure that contains the PSU.
psu_id	Indicates the ID of the PSU in the enclosure.
status	Indicates the status of the power and cooling unit in the enclosure: <ul style="list-style-type: none"> • online indicates that a PSU is present and working normally. • offline indicates that a PSU cannot be detected. • degraded indicates that a PSU is present but not working normally.
input_failed	<ul style="list-style-type: none"> • on indicates that no usable input power is detected from the power distribution unit. • off indicates that the input power is OK.
output_failed	<ul style="list-style-type: none"> • on indicates that no usable output power is detected from the distribution unit. • off indicates that the output power is OK.
input_power	<ul style="list-style-type: none"> • ac indicates that the power supply requires AC power input. • dc indicates that the power supply requires DC power input. • unknown indicates that the power supply is not known or cannot be determined.
fan_failed	<ul style="list-style-type: none"> • on indicates that if the AC, DC, and fan LEDs are all on, there is a PSU fault. If only the fan LED is on, then there is a fan failure. • off indicates that the fans in this PSU are OK.

Table 84. **lsenclosurepsu** output (continued)

Attribute	Description
redundant	Indicates (yes or no) whether you can remove the power supply: <ul style="list-style-type: none"> • If the PSU is on an expansion enclosure, the other PSU must be online. • If the PSU is on a control enclosure, the other PSU must be online and the battery on that PSU must contain enough charge to allow the canisters to dump state and cache data before you shut down.
error_sequence_number	Indicates the error log (or event log) number of the highest priority error for this object. This value is typically blank. However, if there is a problem (for example, the status is degraded), then it contains the sequence number of that error event.
FRU_part_number	Indicates the FRU part number of the PSU.
FRU_identity	Indicates the 11S number, combining the manufacturing part number and the serial number.
firmware_level_1	Indicates the version of the microcode image (power supply firmware version) installed on the power supply.
firmware_level_2	Indicates the version of the power supply metadata (power supply vital product data, or VPD, version) installed on the power supply. Note: This field might not be applicable for some systems and is blank for all PSU types.
firmware_level_3	Indicates the version of the secondary microcode image that is installed on the enclosure's High Efficiency (HE) power supply unit (PSU). Note: This field might not be applicable for some systems and is blank for all PSU types.

An invocation example

```
lsenclosurepsu -delim :
```

The resulting output:

```
enclosure_id:PSU_id:status:input_power
1:1:online:ac
1:2:online:ac
```

A detailed invocation example

```
lsenclosurepsu -psu 1 1
```

The detailed resulting output:

```
enclosure_id 1
PSU_id 1
status online
input_failed off
output_failed on
fan_failed off
redundant yes
error_sequence_number
FRU_part_number 85Y5847
FRU_identity 11S85Y5847YG50CG07W0LJ
firmware_level_1 0314
firmware_level_2 AF9293E5
firmware_level_3
```

```
input_power ac
```

lsenclosuresem

Use the **lsenclosuresem** command to display the status (or any pertinent data) about secondary expander modules (SEM) in a 5U92 system.

Syntax

```
➔ lsenclosuresem -sem sem_id -nohdr -delim delimiter enclosure_id ➔
```

Parameters

-sem sem_id

(Optional) Specifies the SEM ID for the SEM data that is being displayed.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

enclosure_id

(Required) Specifies the enclosure ID for the enclosure data that is being displayed. The value must be an integer 1 - 99.

Description

This command displays the status (or any pertinent data) about SEM in a 5U92 system.

A 5U92 system is a 5U enclosure that can contain up to 92 3.5-inch drives (but must be used in an expansion enclosure).

This table provides the attribute values that can be displayed as output view data.

Table 85. lsenclosuresem output	
Attribute	Description
id	Indicates the enclosure ID of the enclosure that contains the disk drawer. The value must be a number 1 - 99.

Table 85. **lsenclosuresem** output (continued)

Attribute	Description
sem_id	Indicates the SEM ID for the SEM that is in the enclosure. The value must be a number, 1 or 2.
status	Indicates the SEM status for the SEM that is in the enclosure. The values are: <ul style="list-style-type: none"> • online, which indicates that the SEM is online • degraded, which indicates that the SEM is degraded • offline, which indicates that the SEM is offline
expander_1_status	Indicates the status of the first or lowest order expander index. The values are: <ul style="list-style-type: none"> • online, which indicates that the SEM is online • degraded, which indicates that the SEM is degraded • offline, which indicates that the SEM is offline
expander_2_status	Indicates the status of the second expander index (or $e+1$, where e is the lowest-order or first expander index). The values are: <ul style="list-style-type: none"> • online, which indicates that the SEM is online • degraded, which indicates that the SEM is degraded • offline, which indicates that the SEM is offline
error_sequence_number	Indicates the event log sequence number of the current event that is logged against the SEM. The value is blank if there is no error to log.
FRU_part_number	Indicates the field-replaceable unit (FRU) part number for the SEM. The value must be a 7-character numeric string.
FRU_identity	Indicates the FRU ID for the SEM. The value must be a 22-character alphanumeric string.
firmware_level_1	Indicates the SCSI Enclosure Services (SES) firmware level of the lowest order expander index. The value must be a 22-character alphanumeric string.
firmware_level_2	Indicates the bootloader firmware level of the lowest order expander index. The value must be a 22-character alphanumeric string.
firmware_level_3	Indicates the SES firmware level of the second lowest order expander index. (or $s+1$, where s is the lowest-order or first expander index). The value must be a 22-character alphanumeric string.
firmware_level_4	Indicates the bootloader firmware level of the second lowest order expander index. (or $b+1$, where b is the lowest-order or first expander index). The value must be a 22-character alphanumeric string.
firmware_level_5	Indicates the complex programmable logic device (CPLD) firmware level of the lowest order expander index. The value must be a 22-character alphanumeric string.
firmware_level_6	Indicates the CPLD firmware level of the second lowest order expander index (or $c+1$, where c is the lowest-order or first expander index). The value must be a 22-character alphanumeric string.

A concise invocation example

```
lsenclosuresem 1
```

The resulting output:

enclosure_id	sem_id	status	expander1_status	expander2_status
1	1	online	online	online
1	2	online	online	online

A detailed invocation example

```
lsenclosuresem -sem 1 1
```

The resulting output:

```
enclosure_id 1
sem_id 1
status online
expander1_status online
expander2_status online
error_sequence_number
FRU_Part_Number *****
FRU_Identity *****
firmware_level_1 0802.official
firmware_level_2 000E
firmware_level_3 0802.official
firmware_level_4 000E
firmware_level_5 1A.04.E3
firmware_level_6 1A.04.E5
```

lsenclosureslot

Use the **lsenclosureslot** command to view information about each drive slot in the enclosure.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (""):

```
lsenclosureslot -filtervalue "enclosure_id>2"
```

-filtervalue?

(Optional) Displays the valid filter attributes for the **-filtervalue** parameter:

- drive_id
- drive_present
- enclosure_id
- port_1_status
- port_2_status
- slot_id

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. This parameter suppresses the display of these headings.

-slotslot_id

(Optional) Specifies the slot to display information for (it provides a detailed view for that enclosure slot). This parameter is valid only when an enclosure is specified. The value must be a number in the range 1 - 92.

Note:

If slot information is requested for a slot that does not exist on the specified enclosure, value that is displayed is blank.

enclosure_id

(Optional) Lists slots for that enclosure. Must be specified whether **-slot** is used.

Description

This command displays information about each drive slot in the enclosure, such as whether a drive is present, and the port status for that drive. This table shows the possible outputs:

Table 86. <i>lsenclosureslot</i> output	
Attribute	Description
enclosure_id	The identity of the enclosure that contains the drive slot.
slot_id	Identifies which of the drive slots in the enclosure it is.
port_1_status	<p>The status of enclosure slot port 1. If the port is bypassed for multiple reasons, only one is shown. In order of priority, they are:</p> <ul style="list-style-type: none">• online indicates that the enclosure slot port 1 is online• excluded_by_drive indicates that the drive excluded the port• excluded_by_enclosure indicates that the enclosure excluded the port• excluded_by_system indicates that the system excludes the port <p>This field is blank for enclosures with NVMe drives.</p>

Table 86. **lsenclosureslot** output (continued)

Attribute	Description
port_2_status	<p>The status of enclosure slot port 2. If the port is bypassed for multiple reasons, only one is shown. In order of priority, they are:</p> <ul style="list-style-type: none"> • online indicates that the enclosure slot port 2 is online. • excluded_by_drive indicates that the drive excluded the port. • excluded_by_enclosure indicates that the enclosure excluded the port. • excluded_by_system indicates that the system excludes the port. <p>This field is blank for enclosures with NVMe drives.</p>
fault_LED	<p>The state of the combined fault and identify light-emitting diodes (LEDs):</p> <ul style="list-style-type: none"> • off indicates no fault • slow_flashing indicates the identify mode <p>Note: When the LED is in identify mode, it conceals whether there is a fault present (it always flashes). When you remove it from identity mode, the LED is turned on or off.</p> <ul style="list-style-type: none"> • on indicates fault
powered	Indicates whether the slot is powered on. The values are yes or no.
drive_present	Indicates if a drive is in the slot. The drive can be working, dead, or powered off. The values are yes (present) or no (empty).
drive_id	Indicates the ID of the drive in the slot; blank if there is no drive present, or if there is a drive present but it is offline and unmanaged.
error_sequence_number	Indicates the error log number of the highest priority error for this object. This value is typically blank. However, if there is a problem (for example, the status is degraded), then it contains the sequence number of that error.
interface_speed	<p>Indicates the lowest interface speed for the connected drive slot (in gigabits per second, or Gbps). The values are:</p> <ul style="list-style-type: none"> • 1.5 Gbps • 3 Gbps • 6 Gbps • 12 Gbps • Blank if both ports are isolated or the drive is not connected
row	Identifies the row in which the slot appears. The value must be a letter in the range A - G.
column	Identifies the column in which the slot appears. The value must be a number in the range 1 - 14.

A concise invocation example

This example displays information about mappings between the 1 and 2 dimensional IDs

```
lsenclosureslot
```

The resulting output:

```
enclosure_id slot_id port_1_status port_2_status drive_present drive_id row column
1             1      online         online         no             A      1
1             2      online         online         no             A      2

A detailed invocation example showing slot 2 in enclosure 5

```
lsenclosureslot -delim : -slot 2 5
```

The resulting output:

```
enclosure_id:5
slot_id:2
port_1_status:online
port_2_status:online
fault_LED:off
powered:yes
drive_present:yes
drive_id:105
error_sequence_number:
interface_speed:6Gb
```

A detailed invocation example

```
lsenclosureslot -delim :
```

The resulting output:

```
enclosure_id:slot_id:port_1_status:port_2_status:drive_present:drive_id:error_sequence_number
1:1:online:online:yes:22:

[chenclosure](#)

Use the **chenclosure** command to modify enclosure properties.

[chenclosurecanister](#)

Use the **chenclosurecanister** command to modify the properties of an enclosure canister.

[chenclosuredisplaypanel](#)

Use the **chenclosuresdisplaypanel** command to modify the properties for an enclosure display panel.

[chenclosurepsu](#)

Use the **chenclosurepsu** command to modify the properties of an enclosure power-supply unit (PSU).

[chenclosuresem](#)

Use the **chenclosuresem** command to modify the properties of an enclosure SEM.

[chenclosureslot](#)

Use the **chenclosureslot** command to modify the properties of an enclosure slot.

[satask chenclosurevdp](#) (Deprecated)

The **chenclosurevdp** command is deprecated. Use the **chvdp** command instead.

[lsenclosure](#)

Use the **lsenclosure** command to view a summary of the enclosures.

[lsenclosurebattery](#)

Use the **lsenclosurebattery** command to display information about the batteries. The batteries are located in the node canisters.

[lscontrolenclosurecandidate](#) (Storwize family products only)

Use the **lscontrolenclosurecandidate** command to display a list of all control enclosures you can add to the current system.

[lsenclosurecanister](#)

Use the **lsenclosurecanister** command to view a detailed status for each canister in an enclosure.

[lsenclosurechassis](#)

Use the **lsenclosurechassis** command to provide a description of the chassis-specific enclosure properties, including its location within the chassis.

[lsenclosuresdisplaypanel](#)

Use the **lsenclosuresdisplaypanel** command to display information about the display panel in an enclosure.

[lsenclosurefanmodule](#)

Use the **lsenclosurefanmodule** command to report the status of each fan module and the contained fans in an enclosure.

[lsenclosurepsu](#)

Use the **lsenclosurepsu** command to view information about each power-supply unit (PSU) in the enclosure.

[lsenclosuresem](#)

Use the **lsenclosuresem** command to display the status (or any pertinent data) about secondary expander modules (SEM) in a 5U92 system.

[lsenclosurestats](#)

Use the **lsenclosurestats** command to display the most recent values (averaged) of all enclosure statistics. It can also display a history of those values for any subset of the available statistics.

[lssasfabric](#)

Use the **lssasfabric** command to see which canisters are visible to a node, and the order of these canisters.

[resetleds](#)

Use the **resetleds** command to simultaneously switch off all light-emitting diodes (LEDs) in the system, including node battery LEDs.

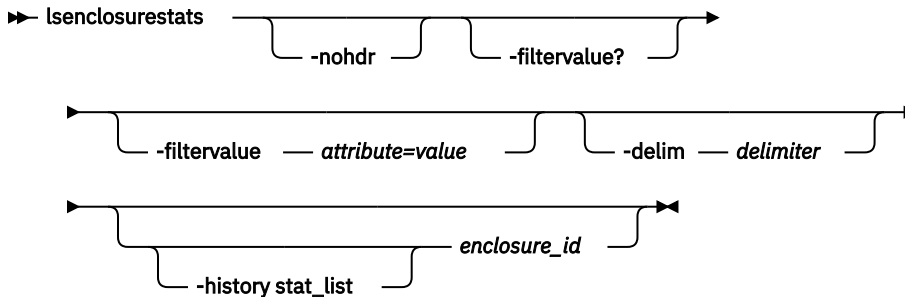

[triggerenclosuredump](#)

Use the **triggerenclosedump** command to force the specified enclosure or enclosures to dump data.

lsenclosurestats

Use the **lsenclosurestats** command to display the most recent values (averaged) of all enclosure statistics. It can also display a history of those values for any subset of the available statistics.

Syntax

Parameters

-history stat_list

(Optional) Produces a history of values for enclosure statistics.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (""):

```
lsenclosurestats -filtervalue "enclosure_id>2"
```

-filtervalue?

(Optional) Displays the valid filter attributes for the **-filtervalue** parameter:

- enclosure_id
- stat_name

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

enclosure_id

(Optional) Indicates the unique enclosure identifier (a number in the range 1 - 99).

Description

Remember: This command cannot be used for products that do not support environmental statistics.

If you specify **-history stat_list** you must also specify *enclosure_id*. Filtering is supported for the concise view but not the detailed view.

Multiple statistical histories can be requested. The limit is the current maximum number of different statistical names published in the concise view. The concise view defines the output order.

For the detailed view, enclosure power is averaged over thirty seconds to provide immediate power.

Note: Averaging applies only to populated samples

Enclosure power is not averaged in the output if **-history** is specified.

The following is an invocation example for products that do not support environmental statistics - a message is displayed:

```
lsenclosurestats
```

This is the resulting output:

```
CMMVC6051E An unsupported action was selected.
```

This table displays information about chassis-specific enclosure properties and shows possible outputs for products that support environmental statistics.

Table 87. lsenclosurestats outputs	
Attribute	Description
enclosure_id	Indicates the enclosure identifier; it can be a numeric character in the range 1 - 264.
sample_time	Indicates the time during which the sample occurred.
stat_name	Indicates the name of the statistical field.
stat_current	Indicates the current value of the statistical field.
stat_peak	Indicates the peak value of the statistic field. The last 5 minutes are used for samples.
stat_peak_time	Indicates the time that the peak occurred.
stat_value	Indicates the value of the statistic.

Remember: Filtering is supported on the *enclosure_id* and *stat_name* fields by using the concise view.

An invocation example

```
lsenclosurestats
```

The resulting output:

```
enclosure_id stat_name stat_current stat_peak stat_peak_time
1 power_w 2200 2500 120402103212
1 temp_c 35 36 120402103212
1 temp_f 95 97 120402103212
2 power_w 2300 2600 120402102917
2 temp_c 36 37 120402102917
2 temp_f 97 98 120402102917
4 power_w 2100 2400 120402103202
```

4	temp_c	33	35	120402103202
4	temp_f	93	95	120402103202

An invocation example

```
lsenclosurestats -history power_w 1
```

The resulting output:

enclosure_id	sample_time	stat_name	stat_value
1	120402105137	power_w	2282

triggerenclosedump

Use the **triggerenclosedump** command to force the specified enclosure or enclosures to dump data.

lssasfabric

Use the **lssasfabric** command to see which canisters are visible to a node, and the order of these canisters.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (""): `lssasfabric -filtervalue "status"`

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter `-delim :` on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue?

(Optional) Displays the valid filter attributes for the **-filtervalue** parameter:

- enclosure_id
- canister_id
- canister_port_id
- control_enclosure_id
- node_canister_id
- node_canister_port_id
- position
- IO_group_id
- IO_group_name
- node_id
- node_name

Description

Use this command to see which canisters are visible to a node, and the order of these canisters. This table describes possible outputs:

<i>Table 89. lssasfabric output</i>	
Attribute	Description
enclosure_id	Indicates the identity of the enclosure the strand goes to.
canister_id	Indicates the canister in the enclosure that the strand goes to.
canister_port_id	Indicates the canister port that the strand goes to.
control_enclosure_id	Indicates the identity of the enclosure that the strand comes from. If the node does not reside inside a canister or an enclosure this field is blank.
node_canister_id	Indicates the identity of the canister the strand comes from. If the node does not reside inside a canister or an enclosure this field is blank.
node_canister_port_id	Indicates the node canister port that the strand is from. This must be the same as the chain ID.
position	Indicates the position in the strand or chain.
IO_group_id	Indicates the I/O group that the strand belongs to. This must be the same as the enclosure IO group.
IO_group_name	Indicates the I/O group the strand belongs to. This must be the same as the enclosure IO group.
node_id	Indicates the identity of the node that the strand is from. This is the same physical object as the node_canister
node_name	The name of the node that the strand is from. This is the same physical object as the node_canister.

An invocation example with three enclosures

Enclosure 1 is the control enclosure. Enclosure 2 is on chain 1 (node canister port 1) using canister port 1 as its connector. Enclosure 3 is on chain 2 (node canister port 2) using canister port 2 as its connector.

```
lssasfabric
```

Note: In this guide, the following output is split into two parts. This is for illustrative purposes; the output does not appear in two parts when you run this command.

This is the first part of the resulting output:

enclosure_id	canister_id	canister_port_id	control_enclosure_id	node_canister_id
1	1	1	1	1
1	2	1	1	2
2	1	1	1	1
2	2	1	1	2
3	1	2	1	1
3	2	2	1	2

This is the second part of the resulting output:

node_canister_port_id	position	IO_group_id	IO_group_name	node_id	node_name
2	0	0	io_grp0	1	node1
2	0	0	io_grp0	2	node2
1	1	0	io_grp0	1	node1
1	1	0	io_grp0	2	node2
2	1	0	io_grp0	1	node1
2	1	0	io_grp0	2	node2

An invocation example with two enclosures

This example shows the output when you use this command for a pair of expansion enclosures that are wired correctly to a set of nodes.

```
lssasfabric
```

The resulting output:

enclosure_id	canister_id	canister_port_id	control_enclosure_id	node_canister_id	node_canister_port_id	position	IO_group_id	IO_group_name	node_id	node_name
1	1	1		1	1	0	0	io_grp0	1	node1
2	1	1		2	1	0	0	io_grp0	1	node1
1	2	1		1	1	0	0	io_grp0	2	node1
2	2	1		2	1	0	0	io_grp0	2	node2

lsenclosureslot

Use the **lsenclosureslot** command to view information about each drive slot in the enclosure.

lsenclosurestats

Use the **lsenclosurestats** command to display the most recent values (averaged) of all enclosure statistics. It can also display a history of those values for any subset of the available statistics.

resetleds

Use the **resetleds** command to simultaneously switch off all light-emitting diodes (LEDs) in the system, including node battery LEDs.

triggerenclosuredump

Use the **triggerenclosuredump** command to force the specified enclosure or enclosures to dump data.

resetleds

Use the **resetleds** command to simultaneously switch off all light-emitting diodes (LEDs) in the system, including node battery LEDs.

Syntax

➤ resetleds ➡

Parameters

None.

Description

The **resetleds** command simultaneously switches off all LEDs in the system, including node battery LEDs. This ensures that any identity LED switched on is the only one in the system that is switched on. This command works only on LEDs that are on systems that can communicate, which means they are online or of a supported type. This command fails if an object is offline, or if the enclosure is an unsupported type. This command does not affect LEDs:

- On independently-controlled objects
- On offline objects
- With hardware-only controls

An invocation example

```
resetleds
```

The resulting output:

```
No feedback
```

Syntax

► triggerenclosedump  **-port** = *port_id* **-iogrp** = *iogrp_id_or_name* **-enclosure** = *enclosure_id* ►

Note:

1. Use just one of the optional parameters (**-port** or **-enclosure**).
2. If **-port** is specified, **-iogrp** must also be specified.
3. If **-iogrp** is specified, **-port** must also be specified.

Parameters

-port*port_id*

(Optional) If the system is wired correctly, this value is identical to the ID of the chain with the enclosures you want to dump. If the system is wired incorrectly, all the enclosures that are connected to port *port_id* of either node canister are dumped.

-iogrp*iogrp_id_or_name*

(Optional) The ID or name of the I/O group the control enclosure belongs to.

-enclosure*enclosure_id*

(Optional) The ID of the enclosure you want to dump.

Description

Important: One of the optional parameters must be specified.

This command requests the canisters in the enclosure or enclosures that are specified to dump data. Then, the dumped data is collected and moved to /dumps/enclosure on the nodes that are connected to the enclosure. There is one file for each canister successfully dumped. The files might be on different nodes. Dumps provide information about your system to your product support personnel, who have tools to interpret the dump data. Use the **cpdumps** command to copy the files from the system. This command does not disrupt access to the enclosures. The system limits the number of enclosure statesaves in the directory to 20 per node.

To trigger enclosure dumps from all enclosures connected to port 1 of the control enclosure in iogrp 2

```
triggerenclosuredump -port 1 -iogrp 2
```

The resulting output:

The data is dumped to the /dumps/enclosure directory if command is successful.

To trigger enclosure dumps from enclosure 5

```
triggerenclosuredump -enclosure 5
```

The resulting output:

The data is dumped to the /dumps/enclosure directory if command is successful.

Use the **lsenclosure** command to view a summary of the enclosures.

[lsenclosurebattery](#)

Use the **lsenclosurebattery** command to display information about the batteries. The batteries are located in the node canisters.

[lscontrolenclosurecandidate](#) (Storwize family products only)

Use the **lscontrolenclosurecandidate** command to display a list of all control enclosures you can add to the current system.

[lsenclosurecanister](#)

Use the **lsenclosurecanister** command to view a detailed status for each canister in an enclosure.

[lsenclosurechassis](#)

Use the **lsenclosurechassis** command to provide a description of the chassis-specific enclosure properties, including its location within the chassis.

lsenclosuredisplaypanel

Use the **lsenclosuredisplaypanel** command to display information about the display panel in an enclosure.

lsenclosurefanmodule

Use the **lsenclosurefanmodule** command to report the status of each fan module and the contained fans in an enclosure.

lsenclosurepsu

Use the **lsenclosurepsu** command to view information about each power-supply unit (PSU) in the enclosure.

lsenclosuresem

Use the **lsenclosuresem** command to display the status (or any pertinent data) about secondary expander modules (SEM) in a 5U92 system.

lsenclosureslot

Use the **lsenclosureslot** command to view information about each drive slot in the enclosure.

lsenclosurestats

Use the **lsenclosurestats** command to display the most recent values (averaged) of all enclosure statistics. It can also display a history of those values for any subset of the available statistics.

lssasfabric

Use the **lssasfabric** command to see which canisters are visible to a node, and the order of these canisters.

resetleds

Use the **resetleds** command to simultaneously switch off all light-emitting diodes (LEDs) in the system, including node battery LEDs.

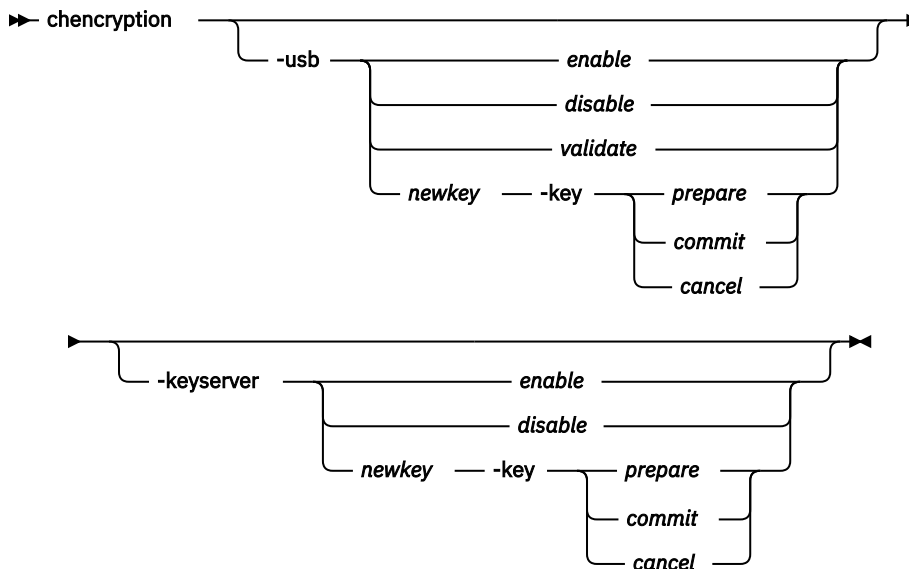

Chapter 13. Encryption commands

Use the encryption and security commands are used to create, change, or list system encryption feature details.

chencryption

Use the **chencryption** command to manage the encryption state of the system.

Syntax

Parameters

-usb enable / disable / validate / newkey

(Required if you do not specify **-keyserver**) Specifies whether USB encryption is enabled (or disabled) or the encryption keys are validated. You can also create new encryption keys that are also stored on Universal Serial Bus (USB) flash drives for use if the system forgets the encryption keys.

-usb enable

Enables encryption capability on the system. Then specify **-usb newkey** to create new keys. Use this command when the system has encryption hardware and encryption licenses (for example, the **lsencryption** value for status is set to **licensed**).

-usb disable

Disables the encryption capability of the system. If no encryption key is prepared this operation is complete and no further action is needed. Do not use this command if an encryption key is prepared or encrypted objects exist.

Remember: This removes all encryption keys (that are not on the USB flash drive) from the system.

-usb validate

Verifies that encryption keys are present on the USB flash drive and makes sure that the keys match the system encryption keys. Use this command when encryption is enabled and encryption keys exist (for example, **lsencryption** value for **usb_rekey** is set to **no**).

-usb newkey

Generates a new encryption key on a USB flash drive that is attached to the system. Use this command only if the minimum number of USB flash drives that can be used as key material stores

are attached to the system (as reported by **lsportusb**). When you specify this parameter, the **-key** option must also be supplied.

-keyserver enable / disable / newkey

(Required if you do not specify **-usb**) Specifies the encryption task that involves encryption keys that are managed by key servers.

-keyserver enable

Enables encryption capability on the system. Use this command when the system has encryption hardware and encryption licenses (for example, the **lsencryption** value for `keyserver_status` is set to `licensed`).

-keyserver disable

Disables the encryption capability of the system. If no encryption key is prepared, this operation is complete and no further action is needed. Do not use this command if an encryption key is prepared or encrypted objects exist.

-keyserver newkey

Generates a new encryption key on the primary key server that is attached the system. You must also specify **-key** when you specify this parameter.

-key prepare / commit / cancel

(Optional) Manages the creation of a new or replacement (rekey) encryption keys when **-usb newkey** or **-keyserver newkey** is specified. There are three stages:

-key prepare

Generates system encryption keys and writes those keys to all system attached USB flash drives or key servers. If there is active encryption key material, confirm that at least one USB flash drive or key server has the current key material. Use this command only when the **lsencryption** value for `usb_rekey` or `keyserver_rekey` is set to `no` or `no_key`.

-key commit

Commits the prepared key as the current key. Use this command when the **lsencryption** value for `usb_rekey` or `keyserver_rekey` is set to `prepared` and the number of USB encryption keys is at least the minimum number required.

-key cancel

Cancels any specified key changes. Use this command when the **lsencryption** value for `usb_rekey` or `keyserver_rekey` is set to `prepared`.

Description

Use this command to manage the encryption state of the system. You must specify either **-usb** or **-keyserver**.

You can use this command can to turn on or turn off USB key encryption or key server encryption (but you cannot disable encryption if there are any encrypted objects). There are four types:

- **enable**, which enables encryption
- **disable**, which disables encryption
- **validate**, which validates encryption

Note: The **validate** option does not apply to key server encryption.

- **newkey**, which specifies a new key for encryption

You can also perform a rekey of the external USB key or key server key material, which is divided into three stages:

- **prepare**, which generates new keys and sets up the system to change encryption keys during apply
- **commit**, which includes applying new keys (and copying key material)
- **cancel**, which rolls back the key setup that is performed during the **prepare** and cancels the rekey request

You cannot perform an enable, disable, or rekey operation for a key provider that is part of a cloud account that is in `import` mode.

You can use both USB flash drive and key server encryption in parallel on the same system. However, you must configure and administer these encryption methods independently.

An invocation example

```
chencryption -usb enable
```

The resulting output:

```
No feedback
```

An invocation example

```
chencryption -usb newkey -key prepare
```

The resulting output:

```
No feedback
```

An invocation example

```
chencryption -usb newkey -key commit
```

The resulting output:

```
No feedback
```

An invocation example

```
chencryption -keyserver enable
```

The resulting output:

```
chencryption -keyserver newkey -key prepare
```

An invocation example

```
chencryption -keyserver newkey -key commit
```

The resulting output:

```
No feedback
```

lskeyserverisklm

Use the **lskeyserverisklm** command to display the system-wide IBM Security Key Lifecycle Manager key server configuration.

lskeyserverkeysecure

Use the **lskeyserverkeysecure** command to display the system-wide Gemalto SafeNet KeySecure (KeySecure) key server configuration.

mkkeyserver

Use the **mkkeyserver** command to create a key server object.

rmkeyserver

Use the **rmkeyserver** command to remove a key server object.

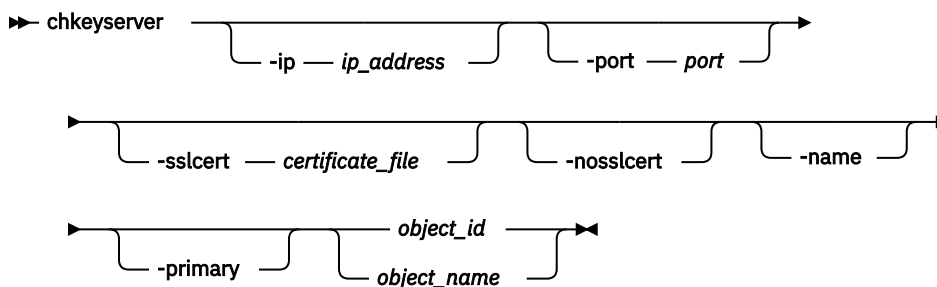

testkeyserver

Use the **testkeyserver** command to test key server objects.

chkeyserver

Use the **chkeyserver** command to change the attributes for a key server object.

Syntax

Parameters

-ip ip_address

(Optional) Specifies the key server's IP address. The value must be in the form of a standard Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) address.

-port port

(Optional) Specifies the key server's TCP/IP port. The value must be a number 1 - 65535. The default value is the same as the default port used for key servers of the currently enabled type.

-sslcert certificate_file

(Optional) Specifies the key server's self-signed certificate. The value must be a file path string.

-nsslcert

(Optional) Specifies the removal of the key server self-signed certificate.

-name

(Optional) Specifies the key server object name. The value must be an alphanumeric string.

-primary

(Optional) Specifies the primary key server.

object_id | object_name

(Required) Specifies the object name or ID that you want to modify.

Description

This command changes the attributes for a key server object.

When a primary key server is configured, that key server must be defined before a rekey operation occurs. A primary object (such as a server) can be configured at any time when a defined primary server is present. A rekey operation without a defined primary key server fails.

An invocation example

```
chkeyserver -primary varyd2
```

The resulting output:

```
No feedback
```

An invocation example

```
chkeyserver -name zlatibr4
```

The resulting output:

```
No feedback
```

An invocation example

```
chkeyserver -sslcert /tmp/yourcert.pem 0
```

The resulting output:

```
No feedback
```

chkeyserverisklm

Use the **chkeyserverisklm** command to change the system-wide IBM Security Key Lifecycle Manager key server configuration.

Syntax

Parameters

-devicegroup *device_group*

(Optional) Specifies a specific device group that the system uses with a key server. The value must be an alphanumeric string no more than 16 characters long.

Note: The specified device name must begin with a letter (not a number) and cannot contain an underscore.

-sslcert *certificate_file*

(Optional) Specifies the certificate authority (CA) certificate for the key server. This parameter cannot be used with **-nsslcert**. The value must be specified in base64-encoded PEM format.

-nsslcert

(Optional) Specifies that the CA certificate on the key server is deleted. This parameter cannot be used with **-sslcert**.

-enable

(Optional) Enables the specified key server type.

-disable

(Optional) Disables the specified key server type.

Important: Do not specify **-disable** with other parameters.

Description

This command changes the system-wide IBM Security Key Lifecycle Manager key server configuration.

An invocation example

```
chkeyserverisklm -devicegroup JVAR_IBRA -sslcert /dumps/CA_certificate.pem -enable
```

The resulting output:

```
No feedback
```

An invocation example

```
chkeyserverisklm -nossllcert
```

The resulting output:

```
No feedback
```

chkeyserverkeysecure

Use the **chkeyserverkeysecure** command to change the system-wide Gemalto SafeNet KeySecure (KeySecure) key server configuration.

Syntax

►► **chkeyserverkeysecure**

Parameters

-sslcert *certificate_file*

(Optional) Specifies the CA certificate that was used to sign the key server certificate.

-nossllcert

(Optional) Removes the existing CA certificate.

-username *user_name*

(Optional) Specifies the user name that is used for authentication with KeySecure. The value must be an alphanumeric string with a maximum of 64 characters.

-nousername

(Optional) Clears the user name that is used for authentication with KeySecure.

-password '*password*'

(Optional) Specifies the password that is used for authentication with KeySecure. The value must be an alphanumeric string with a maximum of 64 characters. **You must enclose the password in single quotation marks.**

-nopassword

(Optional) Clears the password that is used for authentication with KeySecure.

-enable

(Optional) Enables the KeySecure key server type.

-disable

(Optional) Disables the KeySecure key server type.

Description

This command changes the KeySecure key server configuration.

Keep the following items in mind when you use this command:

- The parameters **-sslcert** and **-nossllcert** are mutually exclusive.
- The parameters **-username** and **-nousername** are mutually exclusive.
- The parameters **-password** and **-nopassword** are mutually exclusive.
- The parameters **-sslcert**, **-username**, and **-password** can be set while the status is disabled (or enabled).
- The parameter **-disable** is mutually exclusive with all other parameters.

Some invocation examples

```
chkeyserverkeysecure -sslcert /tmp/keysecureCA.pem -enable
chkeyserverkeysecure -enable
chkeyserverkeysecure -sslcert /dumps/invalid_certificate.pem
CMMVC8794E Invalid certificate file.
chkeyserverkeysecure -nossllcert
chkeyserverkeysecure -enable
CMMVC9128E Cannot enable key server type because it would exceed the permitted number of
enabled key server types.
chkeyserverkeysecure -disable
CMMVC9061E Cannot disable key server type because key server objects of this type exist.
chkeyserverkeysecure -username cryptoadmin -password 'ail4rthi45G1'
chkeyserverkeysecure -nousername -nopassword
```

Syntax

➔ **lsencryption** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) In a detailed view, each item of data has its own row, and if the headings are displayed, the data is separated from the heading by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. In a detailed view, the data is separated from its heading by the specified delimiter.

Description

Use this command to display output that is related to the system encryption state.

This table describes possible outputs.

Table 90. **lsencryption** output

Attribute	Value
status	<p>Indicates the system USB encryption status.</p> <ul style="list-style-type: none"> not_supported, which indicates that the system has no supported encryption function. not_licensed, which indicates that the system supports USB encryption but not all licenses are installed. licensed, which indicates that the system has licenses that are installed for all encryption-capable hardware. enabled, which indicates that system encryption by using USB flash drives is working and ready to create encrypted storage.
error_sequence_number	<p>Indicates the event log sequence number of any problem that affects encryption. If there is no problem, it is blank.</p>
usb_rekey	<p>Indicates the state of the Universal Serial Bus (USB) rekey process.</p> <ul style="list-style-type: none"> no, which indicates that there is no rekey process ongoing, but keys exist. no_key, which indicates that there is no rekey process and keys do not exist. prepared, which indicates that a rekey process is active and the system prepares a new key that is waiting for this command to be issued: chencryption -usb newkey -key commit. committing, which indicates that a commit is in progress.
usb_key_copies	<p>Indicates the number of USB devices that prepared keys are written to.</p>
usb_key_filename	<p>Indicates the name of the file that contains the current encryption key.</p>
usb_rekey_filename	<p>Indicates the name of the file that contains the current prepared encryption key.</p>
keyserver_status	<p>Indicates the encryption status for key server encryption. The values are:</p> <ul style="list-style-type: none"> not_supported, which indicates that the system has no supported encryption function. not_licensed, which indicates that the system supports key server encryption but not all licenses are installed. licensed, which indicates that the system has licenses that are installed for all encryption-capable hardware. enabled, which indicates that system encryption by using key servers is working and ready to create encrypted storage.

lskeyserver

Use the **lskeyserver** command to display the key servers that are available to the system.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

object_id / object_name

(Optional) Specifies the object name or ID that you want to display details for.

Description

This command displays all key servers that are available to the system.

This table provides the attribute values that can be displayed as output view data.

Table 91. ~`lskeyserver output	
Attribute	Description
id	Indicates the key server ID.
name	Indicates the key server name.

Table 91. ~`lskeyserver output (continued)

Attribute	Description
status	Indicates the key server status type. The values are: <ul style="list-style-type: none"> • online • degraded • offline
err_seq_num	Indicates the event log sequence number of the highest priority problem that affects the key server.
IP_address	Indicates the key server Internet Protocol (IP) address.
port	Indicates the key server TCP/IP port.
type	Indicates the key server type.
primary	Indicates whether the server is a primary server.
cert_set	Indicates whether a certificate exists for this key server object.
certificate	Indicates a human-readable description of the SSL certificate. The value reads 0 fields if there is no certificate.

An invocation example

```
lskeyserver
```

The resulting output:

```
id name      status IP_address      port  type  primary cert_set
0  isklm_primary online 10.0.1.54      8709  isklm  yes    yes
1  isklm_backup online 10.0.1.55      8709  isklm  no     yes
2  keyserver2  offline 0:0:0:0:0:ffff:a00:138 1234  isklm  no     no
3  keyserver3  offline 0:0:0:0:0:ffff:a00:139 1234  isklm  no     no
```

An invocation example

```
lskeyserver 0
```

The resulting output:

```
id 0
name keyserver0
status online
err_seq_num
IP_address 10.0.1.54
port 8709
type isklm
primary yes
certificate 0 fields
```

Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This command displays the system-wide IBM Security Key Lifecycle Manager key server configuration.

This table provides the attribute values that can be displayed as output view data.

Table 92. lskeyserverisklm output

Attribute	Description
status	Indicates the key server status type. The values are: <ul style="list-style-type: none"> • disabled • enabled_inactive • prepared • enabled_active
device_group	Indicates the device group. The value is a 16-character alphanumeric string.
certificate	Indicates a human readable description of the server SSL certificate that is generated by the system.

An invocation example

```
lskeyserverisklm
```

The detailed resulting output:

```
status enabled_active
device_group VARDY_SYSTEM
certificate 58 fields
Data:

chencryption

Use the **chencryption** command to manage the encryption state of the system.

chkeyserver

Use the **chkeyserver** command to change the attributes for a key server object.

chkeyserverisklm

Use the **chkeyserverisklm** command to change the system-wide IBM Security Key Lifecycle Manager key server configuration.

chkeyserverkeysecure

Use the **chkeyserverkeysecure** command to change the system-wide Gemalto SafeNet KeySecure (KeySecure) key server configuration.

lsencryption

Use the **lsencryption** command to display system encryption information.

lskeyserver

Use the **lskeyserver** command to display the key servers that are available to the system.

lskeyserverkeysecure

Use the **lskeyserverkeysecure** command to display the system-wide Gemalto SafeNet KeySecure (KeySecure) key server configuration.

mkkeyserver

Use the **mkkeyserver** command to create a key server object.

rmkeyserver

Use the **rmkeyserver** command to remove a key server object.

testkeyserver

Use the **testkeyserver** command to test key server objects.

lskeyserverkeysecure

Use the **lskeyserverkeysecure** command to display the system-wide Gemalto SafeNet KeySecure (KeySecure) key server configuration.

Syntax

➔ lskeyserverkeysecure 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This table shows the possible output:

Table 93. <i>lskeyserverkeysecure</i> output	
Attribute	Description
status	Displays the status of this key server type. The possible values are: <ul style="list-style-type: none">• disabled• enabled_inactive• prepared• enabled_active
username_set	Displays whether a user name is set for this key server type. The values are yes or no.
password_set	Displays whether a password is set for this key server type. The values are yes or no.
certificate	Displays a human readable description of the whole server SSL certificate (as generated by <code>openssl x509 -text</code>). This value is blank if no certificate exists.

An invocation example

```
lskeyserverkeysecure
```

The resulting output:

```
status enabled_active
username_set no
password_set no
certificate 75 fields

chkeyserver

Use the **chkeyserver** command to change the attributes for a key server object.

chkeyserverisklm

Use the **chkeyserverrisklm** command to change the system-wide IBM Security Key Lifecycle Manager key server configuration.

chkeyserverkeysecure

Use the **chkeyserverkeysecure** command to change the system-wide Gemalto SafeNet KeySecure (KeySecure) key server configuration.

lsencryption

Use the **lsencryption** command to display system encryption information.

lskeyserver

Use the **lskeyserver** command to display the key servers that are available to the system.

lskeyserverisklm

Use the **lskeyserverrisklm** command to display the system-wide IBM Security Key Lifecycle Manager key server configuration.

mkkeyserver

Use the **mkkeyserver** command to create a key server object.

rmkeyserver

Use the **rmkeyserver** command to remove a key server object.

testkeyserver

Use the **testkeyserver** command to test key server objects.

mkkeyserver

Use the **mkkeyserver** command to create a key server object.

Syntax

► mkkeyserver **-ip** *ip_address*

-port *port*

-sslcert *certificate_file*

-name

-primary

Parameters

-ip *ip_address*

(Required) Specifies the key server's IP address. The value must be in the form of a standard Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) address.

-port *port*

(Optional) Specifies the key server's TCP/IP port. The value must be a number 1 - 65535. The default value is the same as the default port used for key servers of the currently enabled type.

-sslcert *certificate_file*

(Optional) Specifies the key server's self-signed certificate. The value must be a file path string.

- name

(Optional) Specifies the key server object name. The value must be an alphanumeric string.

-primary

(Optional) Specifies the primary key server.

Description

This command creates a key server object.

The primary key server object is created by specifying **-primary**. If key management is enabled, you must use the primary key server object to create keys.

Note: When a primary key server is configured, that key server must be defined before a rekey operation occurs. A primary object (such as a server) can be configured at any time when a defined primary server is present. When you create keys, the system uses the key server that is configured as the primary key server. For multi-master key server configurations, any key server can be selected as the primary. A rekey operation without a defined primary key server fails.

When a key server object is created, it is automatically validated. If the validation is not successful, the command fails and an error message is displayed.

An invocation example

```
mkkeyserver -ip 10.0.1.54 -sslcert /tmp/isklm_public_server_cert.pem -primary
```

The resulting output:

```
Key Server, id [0], successfully created
```

An invocation example

```
mkkeyserver -ip 9.174.157.3 -name pogba_zibra -sslcert pogba_zibra_system_cert.pem
```

The resulting output:

```
Key Server, id [1], successfully created
```

testkeyserver

Use the **testkeyserver** command to test key server objects.

Syntax

►► testkeyserver 

Parameters

object_id / object_name

(Required) Specifies the object name or ID to be validated.

Description

This command tests key server objects.

An invocation example

```
testkeyserver 0
```

The resulting output:

```
The key server task completed successfully.
```

Chapter 14. Licensing and featurization commands

Use the licensing and featurization commands to work with licensed system functions.

activatefeature

Use the **activatefeature** command to activate a feature (using a license key or keyfile) or feature trial period.

Syntax

Parameters

-trial *feature_id* | *feature_name*

(Optional) Activates the trial period for the feature of the specified ID that uses an unsigned 16-bit integer:

- Valid integer values are 0, 1, and 3.
- Valid names are `turbo_performance`, `easy_tier`, and `remote_mirroring`.

-licensekey *key*

(Optional) Provides the license key to activate a feature that contains 16 hexadecimal characters organized in four groups of four numbers with each group separated by a hyphen (such as 0123-4567-89AB-CDEF).

-licensekeyfile *filepath*

(Optional) Provides the full path-to-file containing all required license information by using an alphanumeric string that contains 1 - 256 characters.

Description

All parameters are mutually exclusive.

A license key file can contain one or more license keys. If you specify a key file, every key in the file is applied to the system. The license key is checked against the node or control enclosure serial number, machine type, and model. If no valid keys exist in the file, the command cannot complete successfully on the system. If you cannot apply a key successfully to the system, the command adds any remaining keys.

You must have one key for each node or control enclosure. Specify `activatefeature -licensekeyfile` with an `.xml` file that contains all node or control enclosure keys. Or, specify `activatefeature -licensekey` one time per node or control enclosure.

If a feature is already activated and you activate a feature again by using a key, the command completes successfully.

Remember:

- You cannot complete a trial when a feature is activated.
- You can activate a feature while a trial is in progress.

An invocation example

```
activatefeature -trial 1
```

The resulting output:

```
Activation of a trial is a one time operation. Are you sure you wish to continue? Yes
```

An invocation example

```
activatefeature -licensekey 0123-4567-89AB-CDEF
```

The resulting output:

```
No feedback
```

An invocation example

```
activatefeature -licensekeyfile /tmp/keyfile.xml
```

The resulting output:

```
No feedback
```

Related reference

[chlicense](#)

Use the **chlicense** command to change license settings for system functions.

[deactivatefeature](#)

Use the **deactivatefeature** command to deactivate a feature or suspend a feature trial period.

[lsfeature](#)

Use the **lsfeature** command to list the features that are available for the current system code release. You can also list trial or entitlement information and license keys.

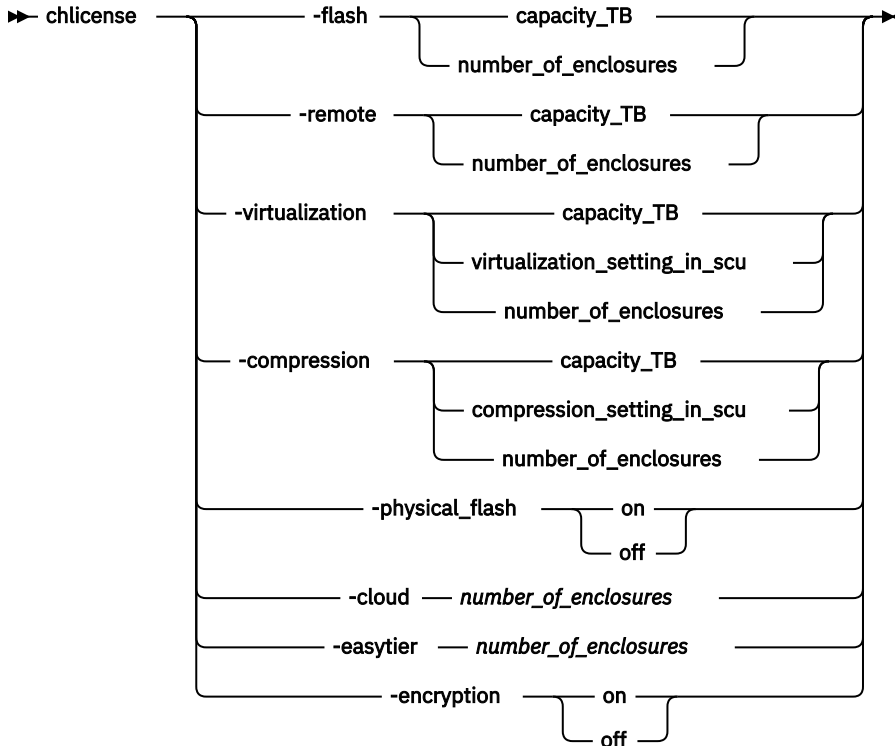

[lslicense](#)

Use the **lslicense** command to display current license settings for system features.

chlicense

Use the **chlicense** command to change license settings for system functions.

Syntax

Parameters

Important: All of the parameters are mutually exclusive. Only one licensing function can be changed at a time.

Remember: Some parameters that are listed might not be applicable to your system or configuration.

-flash capacity_TB | number_of_enclosures

(Required) Changes system licensing for the FlashCopy function. Depending on your system, specify a capacity in terabytes (TB) or specify the total number of internal and external enclosures for the FlashCopy function.

-remote capacity_TB | number_of_enclosures

(Required) Changes system licensing for remote copy functions such as Metro Mirror, Global Mirror, and HyperSwap. Depending on your system, specify a capacity in terabytes (TB) or specify the total number of internal and external enclosures that you have licensed on your system. You must have an enclosure license for all enclosures.

-virtualization capacity_TB | virtualization_setting_in_scu | number_of_enclosures

(Required) Changes system licensing for the Virtualization function. Depending on your system, specify a capacity in terabytes (TB) or specify the total number of storage capacity units (SCUs) that you are licensed to virtualize across tiers of storage on your system or specify the number of enclosures of external storage that you are authorized to use.

-compression capacity_TB | virtualization_setting_in_scu | number_of_enclosures

(Required) Changes system licensing for the compression function. Depending on your system, specify a capacity value in terabytes (TB) or specify the total number of storage capacity units (SCUs) that you are licensed to virtualize across tiers of storage on your system or specify the total number of

internal and external enclosures that you have licensed on your system. Only models that have installed extra memory module (16-GB DIMM) support compression.

-physical_flash_on / off

(Required) For physical disk licensing, this parameter enables or disables the FlashCopy function. The default value is **off**.

-cloud_number_of_enclosures

(Required) Specifies the number of enclosures for the transparent cloud tiering function. The value must be a number. This parameter is not available on all products.

-easytier_number_of_enclosures

(Required) Specifies the number of enclosures on which you can run Easy Tier.

-encryption_on / off

(Required) Specifies whether the encryption license function is enabled or disabled. The values are on or off.

Description

The **chlicense** command changes license settings for the system. Any change that is made is logged as an event in the license setting log.

The capacity for each licensed function can be modified with this command. This value is the number of terabytes (TB) of volume capacity or Storage Control Units (SCU) capacity that can be configured by the system.

The enclosure license already includes virtualization of internal drives on your system. You can use this command to set any additional options. The total number of enclosures in your system must not exceed the total number of licensed enclosures that you have. The total virtualized capacity (number of external enclosures that can be configured by the system) can also be modified with this command. The default is to have no function that is licensed, but it does not stop you from using related functions.

Any error that is placed in the license settings log results in a generic error being placed in the system error log. The command-line tool return code also notifies you that you are using an unlicensed function.

When you reach 90% capacity, any attempt to create or extend volumes, relationships, or mappings generates an error message. You can still create and expand volumes, relationships, or mappings. When usage reaches or exceeds 100% capacity, errors are placed in the license settings log stating that you are using an unlicensed function.

An invocation example for adding a remote copy license capacity of 5 TB

```
chlicense -remote 5
```

The resulting output:

```
No feedback
```

An invocation example for enabling Easy Tier settings

```
chlicense -easytier 2
```

The resulting output:

```
No feedback
```

An invocation example for modifying a compression license value

```
chlicense -compression 4
```

The resulting output:

```
No feedback
```

An invocation example for changing the license on a cloud account

```
chlicense -cloud 2
```

The resulting output:

```
No feedback
```

deactivatefeature

Use the **deactivatefeature** command to deactivate a feature or suspend a feature trial period.

Syntax

```
►► deactivatefeature — feature_id ➡➡
```

Parameters

feature_id

(Required) Deactivates the feature (or feature trial). This ID is the unique ID as displayed when you use the **lsfeature** command, and is an incremental number (in the range 0 - 320).

Description

Use this command to deactivate a feature or suspend a feature trial period.

An invocation example

```
deactivatefeature 1
```

The following output is displayed:

```
You are removing the ability to use a feature of this system. Are you sure you wish to  
continue? Y
```

lslicense

Use the **lslicense** command to display current license settings for system features.

lsfeature

Use the **lsfeature** command to list the features that are available for the current system code release. You can also list trial or entitlement information and license keys.

Syntax

➔ **lsfeature** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-bytes

(Optional) Displays all capacities as bytes.

Description

This command lists the features that are available for the current system code release. You can also list trial or entitlement information and license keys.

This table provides the attribute values that can be displayed as output view data.

Table 94. lsfeature outputs	
Attribute	Possible Values
id	Indicates a number that refers to each feature of the system.

Table 94. **lsfeature** outputs (continued)

Attribute	Possible Values
name	Indicates the feature name with a 16-character alphanumeric string: <ul style="list-style-type: none"> • easy_tier • remote_mirroring • flashcopy_upgrade • turbo_performance • encryption
state	Indicates the current state of the feature: <ul style="list-style-type: none"> • active • inactive • trial_available • trial_active • trial_expired
license_key	Indicates the key that is used in feature activation with a string that consists of 16 hexadecimal characters that are organized in four groups of four numbers with each group that is separated by a hyphen (such as 0123-4567-89AB-CDEF).
trial_expiration_date	Indicates the trial expiration date as long as the state is trial_available or trial_active. This value is displayed in the format YYYYMMDD.
serial_num	Indicates the product serial number.
mtm	Indicates the machine type and model.

Note: A license key's association with an enclosure can be determined if:

- The enclosure that is associated with the key contains at least one node that is added to the cluster and the node is either online or offline at the time the view is queried.
- The enclosure that is associated with the key contains at least one node that is a candidate for clustered system membership. The node must be online at the time the view is being queried.

An invocation example

```
lsfeature
```

The resulting output:

```
id name          state          license_key    trial_expiration_date  serial_num mtm
0  turbo_performance trial_available 20130201
1  easy_tier      trial_active   20130101
2  flashcopy_upgrade active         0123-4567-89AB-CDEF
3  remote_mirroring trial_expired 20130201
```

An invocation example

In this system, both licenses are for encryption. There are two control enclosures, and the serial number and machine type are displayed:

```
lsfeature
```

The resulting output:

id	name	state	license_key	trial_expiration_date	serial_num	mtm
0	encryption	active	90AB-D41D-C799-2EF4		78G00TT	2076-624
1	encryption	active	3A87-463E-B5DF-9969		31G00KG	2076-624

If one of the licenses is removed:

```
lsfeature
```

The resulting output:

id	name	state	license_key	trial_expiration_date	serial_num	mtm
0	encryption	inactive	90AB-D41D-C799-2EF4		78G00TT	2076-624

The state is inactive because control enclosures require their own license to activate encryption.

An invocation example

In this system, both licenses are for encryption. There are two control enclosures, and the serial number and machine type are displayed:

```
lsfeature
```

The resulting output:

id	name	state	license_key	trial_expiration_date	serial_num	mtm
0	encryption	active	90AB-D41D-C799-2EF4		78G00TT	2076-624
1	encryption	active	3A87-463E-B5DF-9969		31G00KG	2076-624

If one of the licenses is removed:

```
lsfeature
```

The resulting output:

id	name	state	license_key	trial_expiration_date	serial_num	mtm
0	encryption	inactive	90AB-D41D-C799-2EF4		78G00TT	2076-624

The state is inactive because control enclosures require their own license to activate encryption.

Use the **deactivatefeature** command to deactivate a feature or suspend a feature trial period.

[lslicense](#)

Use the **lslicense** command to display current license settings for system features.

lslicense

Use the **lslicense** command to display current license settings for system features.

Syntax

➤ **lslicense** -nohdr -delim *delimiter*

Parameters

-nohdr

(Optional) Suppresses the display of these headings. By default, headings are displayed for each column of data (in a concise style view that provides general information about objects of a particular type) and for each item of data (in a detailed style view that provides much more information about a specific object of a particular type).

Note: If there is no data to be displayed, headings are not displayed.

-delim *delimiter*

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :**, a colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

The **lslicense** command displays license settings for system features, including remote copy and virtualization settings.

SAN Volume Controller also includes FlashCopy settings. The displayed output for SAN Volume Controller lists capacity values in terabytes (TB) and feature enablement. The displayed output for Storwize V7000 lists enclosure license values.

Use the **chlicense** command to change the feature license settings. Because the feature license settings are entered when the system is first created, you must update the settings if you change your license.

This table provides the possible values that are applicable to the attributes that are displayed as data in the output views.

Table 95. lslicense output	
Attribute	Possible Values
used_flash	Indicates the amount Flash Copy (FC) memory used.
used_remote	Indicates the amount of remote copy memory used.
used_virtualization	Indicates the amount of virtualization memory used.
license_flash	Indicates the FC license settings.
license_remote	Indicates remote copy license settings.

Table 95. **lslicense** output (continued)

Attribute	Possible Values
license_virtualization	Indicates license virtualization settings.
license_physical_disks	Indicates the amount of physical disk space available for the license.
license_physical_flash	Indicates whether the license physical flash is on or off.
license_physical_remote	Indicates whether the physical remote copy license is on or off.
used_compression_capacity	Indicates the total virtual size of volumes with compressed copies, in total bytes (numeric format with two decimal places).
license_compression_capacity	Indicates the licensed compression capacity, in total bytes (numeric format).
license_compression_enclosures	Indicates which licensed enclosures have compression (numeric format).
license_cloud_enclosures	Indicates whether a separate cloud account system storage license is configured.
scu_ratio_scm	Indicates the storage capacity unit (SCU) ratio for SCM tier storage. The value must be a number with two decimal places.
scu_ratio_ssd	Indicates the storage capacity unit (SCU) ratio for SSD tier storage. The value must be a number with two decimal places.
scu_ratio_enterprise	Indicates the SCU ratio for enterprise tier storage. The value must be a number with two decimal places.
scu_ratio_nearline	Indicates the SCU ration for nearline tier storage. The value must be a number with two decimal places.

An invocation example

```
lslicense
```

The resulting output:

```
used_flash 0.00
used_remote 0.00
used_virtualization 0.00
license_flash 0
license_remote 20
license_virtualization 30
license_physical_disks 0
license_physical_flash on
license_physical_remote off
used_compression_capacity 0.02

license_compression_capacity 0
license_compression_enclosures 1

license_cloud_enclosures 0
scu_ratio_scm 1.00
```

```
scu_ratio_ssd 1.00  
scu_ratio_enterprise 1.18  
scu_ratio_nearline 4.00
```

Use the **activatefeature** command to activate a feature (using a license key or keyfile) or feature trial period.

chlicense

Use the **chlicense** command to change license settings for system functions.

deactivatefeature

Use the **deactivatefeature** command to deactivate a feature or suspend a feature trial period.

lsfeature

Use the **lsfeature** command to list the features that are available for the current system code release. You can also list trial or entitlement information and license keys.

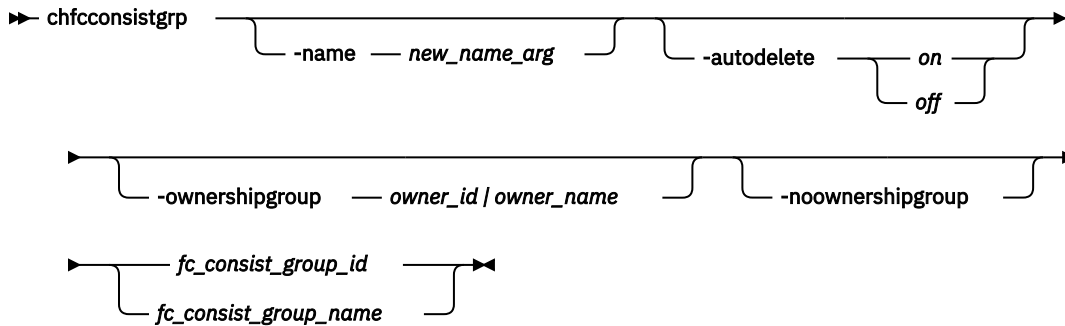

Chapter 15. FlashCopy commands

Use the FlashCopy commands to work with FlashCopy system methods and functions.

chfcconsistgrp

Use the **chfcconsistgrp** command to change the name of a consistency group or mark the group for auto-deletion. You can also change the ownership group.

Syntax

Parameters

-name *new_name_arg*

(Optional) Specifies the new name to assign to the consistency group.

-autodelete *on* / *off*

(Optional) Deletes the consistency group when the last mapping that it contains is deleted or removed from the consistency group.

-ownershipgroup *owner_id* / *owner_name*

(Optional) The name or ID of the ownership group to which the object is being added.

-noownershipgroup

(Optional) If specified, the object is removed from the ownership group to which it belongs.

fc_consist_group_id* / *fc_consist_group_name

(Required) Specifies the ID or existing name of the consistency group that you want to modify.

Description

The **chfcconsistgrp** command changes the name of a consistency group, marks the group for auto-deletion, or both. You can also change the ownership group.

Note: Maps that are *rc_controlled* are not shown in the view when this command is specified.

An invocation example

```
chfcconsistgrp -name testgrp1 fcconsistgrp1
```

The resulting output:

```
No feedback
```

An invocation example changing the ownership of a consistency group

```
chfcconsistgrp -ownershipgroup 2 myconsistgrp
```

The resulting output:

```
No feedback
```

An invocation example moving the **fcconsistgroup** to no ownership

```
chfcconsistgrp -noownershipgroup myconsistgrp
```

The resulting output:

```
No feedback
```

[chfcmap](#)

Use the **chfcmap** command to modify attributes of an existing mapping.

[lsfcconsistgrp](#)

Use the **lsfcconsistgrp** command to display a concise list or a detailed view of FlashCopy consistency groups that are visible to the system. This information is useful for tracking FlashCopy consistency groups.

[lsfcmap](#)

Use the **lsfcmap** command to generate a list that contains concise information about all of the FlashCopy mappings that are visible to the system, or detailed information for a single FlashCopy mapping.

[lsfcmapcandidate](#)

Use the **lsfcmapcandidate** command to list all of the volumes that are associated with fewer than 256 FlashCopy mappings.

[lsfcmapprogress](#)

Use the **lsfcmapprogress** command to display the progress of the background copy of a FlashCopy mapping. This information is displayed as a percentage-completed value.

[lsfcmapdependentmaps](#)

Use the **lsfcmapdependentmaps** command to display the FlashCopy mappings that depend on the user specified mapping.

[lsrmvdiskdependentmaps](#)

Use the **lsrmvdiskdependentmaps** command to display all FlashCopy mappings that must be stopped for the specified volume to be deleted.

[mkfcconsistgrp](#)

Use the **mkfcconsistgrp** command to create a new FlashCopy consistency group and identification name.

[mkfcmap](#)

Use the **mkfcmap** command to create a new FlashCopy mapping, which maps a source volume to a target volume for subsequent copying.

[prestartfcconsistgrp](#)

Use the **prestartfcconsistgrp** command to prepare a consistency group (a group of FlashCopy mappings) so that the consistency group can be started. This command flushes the cache of any data that is destined for the source volume and forces the cache into the write-through mode until the consistency group is started.

[prestartfcmap](#)

Use the **prestartfcmap** command to prepare a FlashCopy mapping so that it can be started. This command flushes the cache of any data that is destined for the source volume and forces the cache into the write-through mode until the mapping is started.

[rmfcconsistgrp](#)

Use the **rmfcconsistgrp** command to delete a FlashCopy consistency group.

[rmfcmap](#)

Use the **rmfcmap** command to delete an existing mapping.

startfcconsistgrp

Use the **startfcconsistgrp** command to start a FlashCopy consistency group of mappings. This command makes a point-in-time copy of the source volumes at the moment that the command is started.

startfcmap

Use the **startfcmap** command to start a FlashCopy mapping. This command makes a point-in-time copy of the source volume at the moment that the command is started.

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

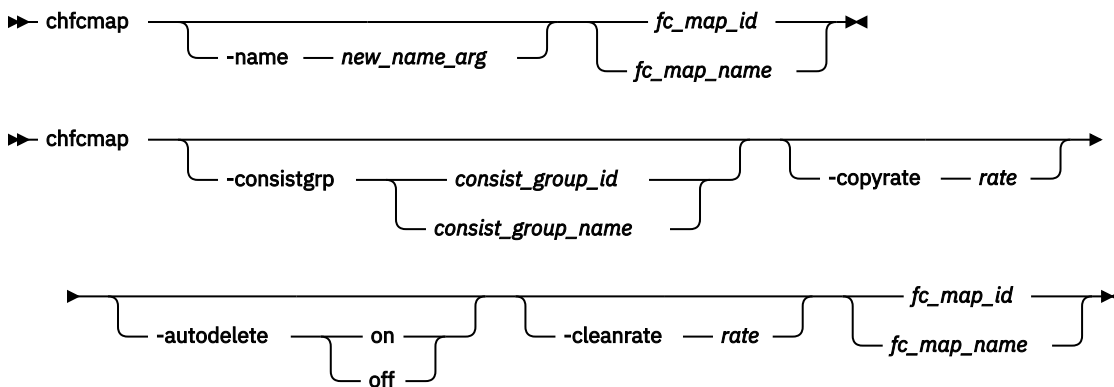

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

chfcmap

Use the **chfcmap** command to modify attributes of an existing mapping.

Syntax

Parameters

-name new_name_arg

(Optional) Specifies the new name to assign to the mapping. The **-name** parameter cannot be used with any other optional parameters.

-consistgrp consist_group_id / consist_group_name

(Optional) Specifies the consistency group for which you want to modify the mapping. To modify a map such that it is stand-alone (not in a consistency group), specify **-consistgrp 0**.

Note: The consistency group cannot be modified if the specified consistency group is in the preparing, prepared, copying, suspended, or stopping state.

-copyrate rate

(Optional) Specifies the copy rate. The **rate** value can be 0 - 150. The default value is 50. A value of 0 indicates no background copy process. For the supported **-copyrate** values and their corresponding rates, see the table in the description.

-autodelete on | off

(Optional) Specifies that the autodelete function be turned on or off for the specified mapping. When you specify the **-autodelete on** parameter, you are deleting a mapping after the background copy completes. If the background copy is already complete, the mapping is deleted immediately.

-cleanrate rate

(Optional) Sets the cleaning rate for the mapping. The *rate* value can be 0 - 150. The default value is 50.

fc_map_id / fc_map_name

(Required) Specifies the ID or name of the mapping to modify. Enter the ID or name last on the command line.

Description

The **chfcmap** command modifies attributes of an existing mapping.

Attention: You must enter the *fc_map_id / fc_map_name* last on the command line.

If you have created several FlashCopy mappings for a group of volumes that contain elements of data for the same application, you can assign these mappings to a single FlashCopy consistency group. You can then issue a single prepare command and a single start command for the whole group, for example, so that all of the files for a particular database are copied at the same time.

The **-copyrate** parameter specifies the copy rate. If 0 is specified, background copy is disabled. The **-cleanrate** parameter specifies the rate for cleaning the target volume. The cleaning process is only active if the mapping is in the copying state and the background copy has completed, the mapping is in the copying state and the background copy is disabled, or the mapping is in the stopping state. You can disable cleaning when the mapping is in the copying state by setting the **-cleanrate** parameter to 0. If the **-cleanrate** is set to 0, the cleaning process runs at the default rate of 50 when the mapping is in the stopping state to ensure that the stop operation completes.

This table provides the relationship of the copy *rate* and cleaning *rate* values to the attempted number of grains to be split per second. A grain is the unit of data represented by a single bit.

<i>Table 96. Relationship between the rate, data rate, and grains per second values</i>			
User-specified rate attribute value	Data copied/sec	256 KB grains/sec	64 KB grains/sec
1 - 10	128 KB	0.5	2
11 - 20	256 KB	1	4
21 - 30	512 KB	2	8
31 - 40	1 MB	4	16
41 - 50	2 MB	8	32
51 - 60	4 MB	16	64
61 - 70	8 MB	32	128
71 - 80	16 MB	64	256
81 - 90	32 MB	128	512
91 - 100	64 MB	256	1024
101 - 110	128 MB	512	2048
111 - 120	256 MB	1024	4096
121 - 130	512 MB	2048	8192
131 - 140	1 GB	4096	16384
141 - 150	2 GB	8192	32768

Note: Maps that are *rc_controlled* are not shown in the view when this command is specified.

An invocation example

```
chfcmap -name testmap 1
```

The resulting output:

```
No feedback
```

Example **lsfcmap** output where map 0 is in consistency group 1

```
lsfcmap
```

The resulting output:

id	name	source_vdisk_id	source_vdisk_name	target_vdisk_id	target_vdisk_name	group_id
group_name	status	progress	copy_rate	clean_progress	incremental	partner_FC_id
partner_FC_name	restoring	start_time	rc_controlled			
0	fcmap0	12	vdisk0	13	vdisk1	1
fccstgrp0	idle_or_copied	0	50	100		
off			no		no	

Example to use **chfcmap** to turn map 0 into a stand-alone mapping

```
chfcmap -consistgrp 0 0
```

The resulting output:

```
No feedback
```

Example **lsfcmap** output where map 0 is no longer in a consistency group

```
lsfcmap
```

The resulting output:

id	name	source_vdisk_id	source_vdisk_name	target_vdisk_id	target_vdisk_name	group_id
group_name	status	progress	copy_rate	clean_progress	incremental	partner_FC_id
partner_FC_name	restoring	start_time	rc_controlled			
0	fcmap0	12	vdisk0	13		
vdisk1			idle_or_copied	0	50	100
off			no		no

Use the **lsfcconsistgrp** command to display a concise list or a detailed view of FlashCopy consistency groups that are visible to the system. This information is useful for tracking FlashCopy consistency groups.

[lsfcmap](#)

Use the **lsfcmap** command to generate a list that contains concise information about all of the FlashCopy mappings that are visible to the system, or detailed information for a single FlashCopy mapping.

[lsfcmapcandidate](#)

Use the **lsfcmapcandidate** command to list all of the volumes that are associated with fewer than 256 FlashCopy mappings.

[lsfcmapprogress](#)

Use the **lsfcmapprogress** command to display the progress of the background copy of a FlashCopy mapping. This information is displayed as a percentage-completed value.

lsfcmapdependentmaps

Use the **lsfcmapdependentmaps** command to display the FlashCopy mappings that depend on the user specified mapping.

lsrmvdiskdependentmaps

Use the **lsrmvdiskdependentmaps** command to display all FlashCopy mappings that must be stopped for the specified volume to be deleted.

mkfcconsistgrp

Use the **mkfcconsistgrp** command to create a new FlashCopy consistency group and identification name.

mkfcmap

Use the **mkfcmap** command to create a new FlashCopy mapping, which maps a source volume to a target volume for subsequent copying.

prestartfcconsistgrp

Use the **prestartfcconsistgrp** command to prepare a consistency group (a group of FlashCopy mappings) so that the consistency group can be started. This command flushes the cache of any data that is destined for the source volume and forces the cache into the write-through mode until the consistency group is started.

prestartfcmap

Use the **prestartfcmap** command to prepare a FlashCopy mapping so that it can be started. This command flushes the cache of any data that is destined for the source volume and forces the cache into the write-through mode until the mapping is started.

rmfcconsistgrp

Use the **rmfcconsistgrp** command to delete a FlashCopy consistency group.

rmfcmap

Use the **rmfcmap** command to delete an existing mapping.

startfcconsistgrp

Use the **startfcconsistgrp** command to start a FlashCopy consistency group of mappings. This command makes a point-in-time copy of the source volumes at the moment that the command is started.

startfcmap

Use the **startfcmap** command to start a FlashCopy mapping. This command makes a point-in-time copy of the source volume at the moment that the command is started.

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

lsfcconsistgrp

Use the **lsfcconsistgrp** command to display a concise list or a detailed view of FlashCopy consistency groups that are visible to the system. This information is useful for tracking FlashCopy consistency groups.

The list report style can be used to obtain two styles of report:

- A list that contains concise information about all of the FlashCopy consistency groups on a system. (Each entry in the list corresponds to a single FlashCopy consistency group.)
- The detailed information about a single FlashCopy consistency group.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are returned.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the SAN Volume Controller CLI:

- The wildcard character is an asterisk character (*).
- The command can contain a maximum of one wildcard, which must be the first or last character in the string.
- When you use a wildcard, surround the filter entry with double quotation marks (" "), as follows:

```
lsfcconsistgrp -filtervalue "name=md*"
```

-nohdr

(Optional) By default, headings are displayed for each item of data in a concise view. The **-nohdr** parameter suppresses the display of these headings. Detailed view is not valid for this command.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, the headers are displayed, and the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 01-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

object_id / object_name

(Optional) Specifies the name or ID of an object. When you use this parameter, the detailed view of the specific object is returned and any value that is specified by the **-filtervalue** parameter returns an error message. If you do not specify the **object_id** or **object_name** parameter, the concise view of all objects that match the filtering requirements that are specified by the **-filtervalue** parameter are displayed.

-filtervalue?

(Optional) Displays the list of valid filter attributes in the report. The valid filter attributes for the **lsfcconsistgrp** command are:

- name
- id
- status
- FC_group_id

Description

This command returns a concise list or a detailed view of FlashCopy consistency groups that are visible to the system.

The following list provides values of the status attribute that are displayed as data in the output views:

status

Indicates the status. The values are:

- idle_or_copied
- preparing
- prepared
- copying
- stopped
- suspended
- stopping
- Empty

id

Indicates the mapping ID.

name

Indicates the mapping name.

start_time

Indicates the time that the group was started in YYYYMMDDHHMMSS format (or blank).

autodelete

Indicates whether auto deletion is on or off.

FC_mapping_id

Indicates the FlashCopy mapping ID.

FC_mapping_name

Indicates the FlashCopy mapping name.

owner_id

Indicates the ID of the ownership group.

owner_name

Indicates the name of the ownership group.

A concise invocation example

```
lsfcconsistgrp -delim :
```

The concise resulting output:

```
id:name:status:start_time
1:ffccg0:empty:060627083237
2:ffccg1:idle_or_copied:060627083337
3:ffccg2:idle_or_copied:060627083437
```

A detailed invocation example

```
lsfcconsistgrp -delim : 1
```

The detailed resulting output:

```
id:1
name:ffccg0
status:empty
```

A detailed invocation example

```
lsfcconsistgrp -delim : fccstgrp0
```

The detailed resulting output:

```
id:1
name:FCcgrp0
status:idle_or_copied
start_time:060627083137
autodelete:off
FC_mapping_id:0
FC_mapping_name:fcmap0
FC_mapping_id:1
FC_mapping_name:fcmap1
owner_id:0
owner_name:tenantA
```

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

lsfcmap

Use the **lsfcmap** command to generate a list that contains concise information about all of the FlashCopy mappings that are visible to the system, or detailed information for a single FlashCopy mapping.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the SAN Volume Controller CLI:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (" "), as follows:

```
lsfcmap -filtervalue "name=md*"
```

-filtervalue?

(Optional) Displays the valid filter attributes for the **-filtervalue attribute=value** parameter:

- name
- id
- source_vdisk_id
- source_vdisk_name
- target_vdisk_id
- target_vdisk_name
- group_name

- group_id
- status
- copy_rate
- FC_mapping_name
- FC_id
- partner_FC_id
- partner_FC_name
- restoring

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **delim** parameter overrides this behavior. Valid input for the **delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

object_id / object_name

(Optional) Specifies the name or ID of an object. When you use this parameter, the detailed view of the specific object is returned and any value that is specified by the **filtervalue** parameter is ignored. If you do not specify the **object_ID** or **object_name** parameter, the concise view of all objects that match the filtering requirements that are specified by the **filtervalue** parameter are displayed.

Description

This command returns a concise list or a detailed view of FlashCopy mappings that are visible to the system.

The following list shows attribute values that can be displayed as output view data:

id

Displays the mapping ID.

name

Displays the mapping name.

source_vdisk_id

Displays the source volume ID.

source_vdisk_name

Displays the source volume name.

target_vdisk_id

Displays the target volume ID.

target_vdisk_name

Displays the target volume name.

group_id

Displays the group ID.

group_name

Displays the group name.

status

Displays the status:

- idle_or_copied
- preparing
- prepared
- copying
- stopped
- suspended
- stopping

progress

Displays the progress.

copy_rate

Displays the copy rate.

start_time

Displays the time that the copy was last started. It is in the format YYMMDDHHMMSS. If a copy is not started, a blank line is displayed.

dependent_mappings

Displays any dependent mappings.

autodelete

Specifies if autodelete is on or off.

clean_progress

Indicates the clean progress.

clean_rate

Indicates the clean rate.

incremental

Indicates whether incremental is on or off.

difference

Indicates the difference.

IO_group

Displays the I/O group ID.

IO_group_name

Displays the I/O group name.

partner_FC_id

Displays the partner FlashCopy ID.

partner_FC_name

Displays the partner FlashCopy name.

restoring

Displays the restoring status. The values are yes or no.

rc_controlled

Displays the rc_controlled status.

copy_rate_mb

Displays the copy rate MB amount.

clean_rate_mb

Displays the clean rate MB amount.

keep_target

Displays the target and source volume availability. The values are:

- yes indicates that the source volume availability is connected to the availability of the target volume.

- no indicates that if there is a problem with the target volume that can impact FlashCopy operations, the target volume is removed.

restore_progress

Displays the percentage of the source volume that is restored from the target.

owner_id

Indicates the ID of the ownership group.

owner_name

Indicates the name of the ownership group.

Note: Using `rc_controlled` indicates that the map is for internal use only. It cannot be manipulated externally.

A concise invocation example

```
lsfcmap -delim :
```

The concise resulting output:

```
id name source_vdisk_id:source_vdisk_name:target_vdisk_id:target_vdisk_name:group_id
  group_name:status:progress:copy_rate:clean_progress:incremental:partner_FC_id:
  partner_FC_name:restoring:start_time:rc_controlled
0:test:0:vdisk0:1:vdisk1:idle_or_copied:0:50:100:off:no
no0:fcmap0:0:vdisk0:1:vdisk1:0:fccstgrp0:idle_or_copied:0:50:0:on:2:fcmap2:no
1:fcmap1:2:vdisk2:3:vdisk3:0:fccstgrp0:idle_or_copied:0:0:100:off::no
2:fcmap2:1:vdisk1:0:vdisk0:0:fccstgrp1:idle_or_copied:0:0:100:off:0:fcmap0:noowner_id:0:owner_na
me:tenantA
```

A detailed invocation example

```
lsfcmap 0
```

The detailed resulting output:

```
id:0
name:fcmap0
source_vdisk_id:63
source_vdisk_name:vdisk63
target_vdisk_id:57
target_vdisk_name:vdisk57
group_id:
group_name:
status:idle_or_copied
progress:0
copy_rate:0
start_time:
dependent_mappings:0
autodelete:off
clean_progress:100
clean_rate:50
incremental:off
difference:100
grain_size:256
IO_group_id:1
IO_group_name:io_grp1
partner_FC_id:
partner_FC_name:
restoring:no
rc_controlled:no
keep_target:yes

restore_progress:

lsfcmapcandidate

Use the **lsfcmapcandidate** command to list all of the volumes that are associated with fewer than 256 FlashCopy mappings.

Syntax

► **lsfcmapcandidate** 

Parameters

-nohdr

(Optional) By default, the heading is displayed for the column of data in a concise style view, and for the item of data in a detailed style view. The **-nohdr** parameter suppresses the display of the heading.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, a colon character (:) separates all items of data in a concise view; the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This command returns a list of volumes that are associated with fewer than 256 FlashCopy mappings.

An invocation example

```
lsfcmapcandidate
```

The resulting output:

```
id
2
3
4
```

Use the **rmfcconsistgrp** command to delete a FlashCopy consistency group.

rmfcmap

Use the **rmfcmap** command to delete an existing mapping.

startfcconsistgrp

Use the **startfcconsistgrp** command to start a FlashCopy consistency group of mappings. This command makes a point-in-time copy of the source volumes at the moment that the command is started.

startfcmap

Use the **startfcmap** command to start a FlashCopy mapping. This command makes a point-in-time copy of the source volume at the moment that the command is started.

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

lsfcmapprogress

Use the **lsfcmapprogress** command to display the progress of the background copy of a FlashCopy mapping. This information is displayed as a percentage-completed value.

Syntax

```
➔ lsfcmapprogress [-nohdr] [-delim delimiter] [fcmap_id | fcmap_name] ➔
```

Parameters

-nohdr

(Optional) By default, headings are displayed for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim *delimiter*

(Optional) By default, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the data is separated from its header by a colon character (:).

fcmap_id | *fcmap_name*

(Required) Specifies that you want the report to display the progress of the background copy for the designated FlashCopy mapping.

Description

This command reports a percentage for the progress of the background copy being copied on the specified FlashCopy mapping.

An invocation example

```
lsfcmapprogress 0
```

The resulting output:

```
id      progress
0              0
```

lsfcmapdependentmaps

Use the **lsfcmapdependentmaps** command to display the FlashCopy mappings that depend on the user specified mapping.

Syntax

➔ **lsfcmapdependentmaps** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: With no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

fc_id / fc_name

(Required) Specifies the name or ID of the FlashCopy mapping to list the dependent maps for.

Description

This command returns a list of dependent FlashCopy mappings. This command can be used to determine the list of FlashCopy mappings that would also stop if you stopped a mapping by using the **-force** parameter.

Use the `dependent_mapping_count` field in the FlashCopy map detailed view (displayed when you process the **lsfcmap** command) as an indicator of dependent mappings in progress. A count of zero means no dependent copies.

Note: Time lapses from processing the **lsfcmap** command to processing the **lsfcmapdependentmaps** command can cause differences between the number of dependent mappings that are being processed and the number that the **lsfcmap** command shows.

An invocation example

```
lsfcmapdependentmaps -delim : 2
```

The resulting output:

```
fc_id:fc_name
1:fcmap1
3:fcmap3
```

chfcmap

Use the **chfcmap** command to modify attributes of an existing mapping.

lsfcconsistgrp

Use the **lsfcconsistgrp** command to display a concise list or a detailed view of FlashCopy consistency groups that are visible to the system. This information is useful for tracking FlashCopy consistency groups.

lsfcmap

Use the **lsfcmap** command to generate a list that contains concise information about all of the FlashCopy mappings that are visible to the system, or detailed information for a single FlashCopy mapping.

lsfcmapcandidate

Use the **lsfcmapcandidate** command to list all of the volumes that are associated with fewer than 256 FlashCopy mappings.

lsfcmapprogress

Use the **lsfcmapprogress** command to display the progress of the background copy of a FlashCopy mapping. This information is displayed as a percentage-completed value.

lsrmvdiskdependentmaps

Use the **lsrmvdiskdependentmaps** command to display all FlashCopy mappings that must be stopped for the specified volume to be deleted.

mkfcconsistgrp

Use the **mkfcconsistgrp** command to create a new FlashCopy consistency group and identification name.

mkfcmap

Use the **mkfcmap** command to create a new FlashCopy mapping, which maps a source volume to a target volume for subsequent copying.

prestartfcconsistgrp

Use the **prestartfcconsistgrp** command to prepare a consistency group (a group of FlashCopy mappings) so that the consistency group can be started. This command flushes the cache of any data that is destined for the source volume and forces the cache into the write-through mode until the consistency group is started.

prestartfcmap

Use the **prestartfcmap** command to prepare a FlashCopy mapping so that it can be started. This command flushes the cache of any data that is destined for the source volume and forces the cache into the write-through mode until the mapping is started.

rmfcconsistgrp

Use the **rmfcconsistgrp** command to delete a FlashCopy consistency group.

rmfcmap

Use the **rmfcmap** command to delete an existing mapping.

startfcconsistgrp

Use the **startfcconsistgrp** command to start a FlashCopy consistency group of mappings. This command makes a point-in-time copy of the source volumes at the moment that the command is started.

startfcmap

Use the **startfcmap** command to start a FlashCopy mapping. This command makes a point-in-time copy of the source volume at the moment that the command is started.

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

lsrmvdiskdependentmaps

Use the **lsrmvdiskdependentmaps** command to display all FlashCopy mappings that must be stopped for the specified volume to be deleted.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

vdisk_name / vdisk_id

(Required) Specifies the name or ID of the volume for which the FlashCopy mappings are displayed.

Description

This command returns a list of the FlashCopy mappings that must be stopped before the specified volume can be deleted. Any mappings that are returned in the list for the volume are automatically stopped when the volume is deleted with the **force** option.

An invocation example

```
lsrmvdiskdependentmaps -delim : 0
```

The resulting output:

```
id:name
2:fcmap2
5:fcmap5
```

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

mkfcconsistgrp

Use the **mkfcconsistgrp** command to create a new FlashCopy consistency group and identification name.

Syntax

```
➔ mkfcconsistgrp -name consist_group_name -autodelete  
-ownershipgroup owner_id / owner_name
```

Parameters

-name *consist_group_name*

(Optional) Specifies a name for the consistency group. If you do not specify a consistency group name, a name is automatically assigned to the consistency group. For example, if the next available consistency group ID is id=2, the consistency group name is fccstgrp2.

Note: Consistency group names must be an alphanumeric string of up to 15 characters.

-autodelete

(Optional) Deletes the consistency group when the last mapping that it contains is deleted or removed from the consistency group.

-ownershipgroup *owner_id / owner_name*

(Optional) The name or ID of the ownership group to which the object is being added.

Description

This command creates a new consistency group and identification name. The ID of the new group is displayed when the command process completes.

If you have created several FlashCopy mappings for a group of volumes that contain elements of data for the same application, you might find it convenient to assign these mappings to a single FlashCopy consistency group. You can then issue a single prepare command and a single start command for the whole group, for example, so that all of the files for a particular database are copied at the same time.

Note: Maps that are `rc_controlled` are not shown in the view when this command is specified.

Remember: Names representing Metro Mirror or Global Mirror consistency groups relationships are restricted to fifteen characters in length (not sixty-three for an extended character set).

An invocation example

```
mkfcconsistgrp
```

The resulting output:

```
FlashCopy Consistency Group, id [1], successfully created
```

startfcmap

Use the **startfcmap** command to start a FlashCopy mapping. This command makes a point-in-time copy of the source volume at the moment that the command is started.

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

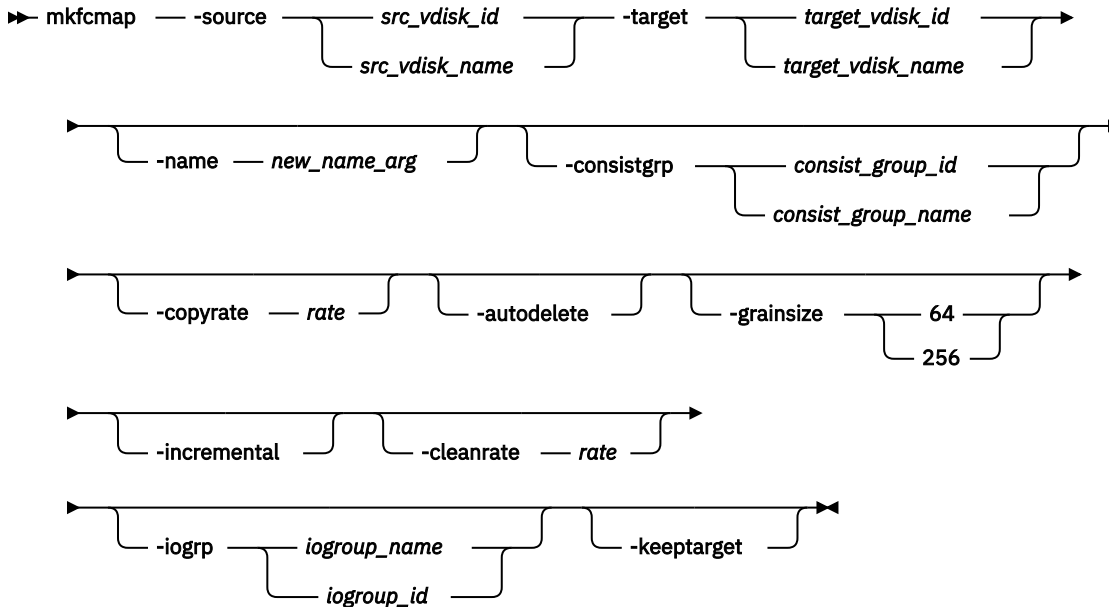

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

mkfcmap

Use the **mkfcmap** command to create a new FlashCopy mapping, which maps a source volume to a target volume for subsequent copying.

Syntax

Parameters

-source *src_vdisk_id* | *src_vdisk_name*

(Required) Specifies the ID or name of the source volume.

-target *target_vdisk_id* | *target_vdisk_name*

(Required) Specifies the ID or name of the target volume.

-name *new_name_arg*

(Optional) Specifies the name to assign to the new mapping.

-consistgrp *consist_group_id* | *consist_group_name*

(Optional) Specifies the consistency group to add the new mapping to. If you do not specify a consistency group, the mapping is treated as a stand-alone mapping.

-copyrate *rate*

(Optional) Specifies the copy rate. The *rate* value can be 0 - 150. The default value is 50. A value of 0 indicates no background copy process. For the supported **-copyrate** values and their corresponding rates, see the table in the command description.

-autodelete

(Optional) Specifies that a mapping is to be deleted when the background copy completes. The default, which applies if this parameter is not entered, is that **autodelete** is set to off.

-grainsize 64 | 256

(Optional) Specifies the grain size for the mapping. The default value is 256. After set, this value cannot be changed.

Remember: If either the source or target disk contains compressed copies, the default value is 64 (unless source or target disk is part of a mapping with grain size 256 KB).

-incremental

(Optional) Marks the FlashCopy mapping as an incremental copy. The default is nonincremental. After set, this value cannot be changed.

-cleanrate *rate*

(Optional) Sets the cleaning rate for the mapping. The *rate* value can be 0 - 150. The default value is 50.

-iogrp *iogroup_name* / *iogroup_id*

(Optional) Specifies the I/O group for the FlashCopy bitmap. After set, this value cannot be changed. The default I/O group is either the source volume, if a single target map, or the I/O group of the other FlashCopy mapping to which either the source or target volumes belong.

Note: If not enough bitmap space is available to complete this command, more space is automatically allocated in the bitmap memory (unless the maximum bitmap memory is reached).

-keeptarget

(Optional) Specifies that the target volume and source volume availability should be kept the same. If the target becomes unavailable, the source is also made unavailable (instead of stopping the FlashCopy mapping).

Description

This command creates a new FlashCopy mapping. This mapping persists until it is manually deleted, or until it is automatically deleted when the background copy completes and the **autodelete** parameter is set to on. The source and target volumes must be specified on the **mkfcmap** command. The **mkfcmap** command fails if the source and target volumes are not identical in size. Issue the **lsvdisk -bytes** command to find the exact size of the source volume for which you want to create a target disk of the same size. The target volume that you specify cannot be a target volume in an existing FlashCopy mapping. A mapping cannot be created if the resulting set of connected mappings exceeds 256 connected mappings.

The mapping can optionally be given a name and assigned to a consistency group, which is a group of mappings that can be started with a single command. These are groups of mappings that can be processed at the same time. It enables multiple volumes to be copied at the same time, which creates a consistent copy of multiple disks. This consistent copy of multiple disks is required by some database products in which the database and log files reside on different disks.

If the specified source and target volumes are the target and source volumes, respectively, of an existing mapping, then the mapping that is being created and the existing mapping become partners. If one mapping is created as incremental, then its partner is automatically incremental. A mapping can have only one partner.

You can create a FlashCopy mapping in which the target volume is a member of a Metro Mirror or Global Mirror relationship, unless one of the following conditions applies:

- The relationship is with a clustered system that is running an earlier code level.
- The I/O group for the mapping is different than the I/O group for the proposed mapping target volume.

Note: You cannot use this command if a volume is part of a mapping and cloud snapshot is enabled on the volume.

The **copyrate** parameter specifies the copy rate. If 0 is specified, background copy is disabled. The **cleanrate** parameter specifies the rate for cleaning the target volume. The cleaning process is only active if the mapping is in the copying state and the background copy is completed, the mapping is in the copying state and the background copy is disabled, or the mapping is in the stopping state. You can disable cleaning when the mapping is in the copying state by setting the **cleanrate** parameter to 0. If the **cleanrate** is set to 0, the cleaning process runs at the default rate of 50 when the mapping is in the stopping state to ensure that the stop operation completes.

Note: You cannot issue this command if any of the following conditions apply:

- The target volume is a master or auxiliary volume in an active-active relationship.

- The source volume is a master or auxiliary volume in an active-active relationship and the target volume and map are not in the same site as the source volume.

This table provides the relationship of the copy rate and cleaning rate values to the attempted number of grains to be split per second. A grain is the unit of data that is represented by a single bit.

Note: The default grain size of 64 KB for compressed volumes applies only to compressed volumes in regular pools if:

- Either the source or target volumes are compressed within a regular pool.
- Either the source or target volumes are themselves sources or targets of compressed volumes in regular pools (i.e. in a cascade where other volumes in the cascade are compressed volumes in a regular pool).

Otherwise, the default grain size is 256 KB for data reduction compressed volumes, provided the volumes are not involved in cascades with compressed volumes in regular pools.

<i>Table 97. Relationship between the rate, data rate, and grains per second values</i>			
User-specified rate attribute value	Data copied/sec	256 KB grains/sec	64 KB grains/sec
1 - 10	128 KB	0.5	2
11 - 20	256 KB	1	4
21 - 30	512 KB	2	8
31 - 40	1 MB	4	16
41 - 50	2 MB	8	32
51 - 60	4 MB	16	64
61 - 70	8 MB	32	128
71 - 80	16 MB	64	256
81 - 90	32 MB	128	512
91 - 100	64 MB	256	1024
101 - 110	128 MB	512	2048
111 - 120	256 MB	1024	4096
121 - 130	512 MB	2048	8192
131 - 140	1 GB	4096	16384
141 - 150	2 GB	8192	32768

Remember: This command cannot be used on a volume that is owned by a file system.

Note: Maps that are rc_controlled are not shown in the view when this command is specified.

An invocation example

```
mkfcmap -source 0 -target 2 -name mapone
```

The resulting output:

```
FlashCopy Mapping, id [1], successfully created
```

An invocation example

```
mkfcmap -source 0 -target 2 -name mapone -keeptarget
```

The resulting output:

```
FlashCopy Mapping, id [1], successfully created
```

prestartfcconsistgrp

Use the **prestartfcconsistgrp** command to prepare a consistency group (a group of FlashCopy mappings) so that the consistency group can be started. This command flushes the cache of any data that is destined for the source volume and forces the cache into the write-through mode until the consistency group is started.

Syntax

➔ **prestartfcconsistgrp** 

Parameters

-restore

(Optional) Specifies the restore flag. This forces the consistency group to be prepared even if the target volume of one of the mappings in the consistency group is being used as a source volume of another active mapping. An active mapping is in the copying, suspended, or stopping state.

fc_consist_group_id | fc_consist_group_name

(Required) Specifies the name or ID of the consistency group that you want to prepare.

Description

This command prepares a consistency group (a group of FlashCopy mappings) to subsequently start. The preparation step ensures that any data that resides in the cache for the source volume is first flushed to disk. This step ensures that the FlashCopy target volume is identical to what has been acknowledged to the host operating system as having been written successfully to the source volume.

You can use the **restore** parameter to force the consistency group to be prepared even if the target volume of one or more mappings in the consistency group is being used as a source volume of another active mapping. In this case the mapping restores as shown in the **lsfcmap** view. If the **restore** parameter is specified when preparing a consistency group where none of the target volumes are the source volume of another active mapping, then the parameter is ignored.

You must issue the **prestartfcconsistgrp** command to prepare the FlashCopy consistency group before the copy process can be started. When you have assigned several mappings to a FlashCopy consistency group, you must issue a single prepare command for the whole group to prepare all of the mappings at once.

The consistency group must be in the `idle_or_copied` or `stopped` state before it can be prepared. When you enter the **prestartfcconsistgrp** command, the group enters the preparing state. After the preparation is complete, the consistency group status changes to `prepared`. At this point, you can start the group.

If FlashCopy mappings are assigned to a consistency group, the preparing and the subsequent starting of the mappings in the group must be performed on the consistency group rather than on an individual FlashCopy mapping that is assigned to the group. Only stand-alone mappings, which are mappings that are not assigned to a consistency group, can be prepared and started on their own. A FlashCopy consistency group must be prepared before it can be started.

This command is rejected if the target of a FlashCopy mapping in the consistency group is in a remote copy relationship, unless the relationship is one of the following types and is the secondary target of the remote copy:

- idling
- disconnected
- consistent_stopped
- inconsistent_stopped

The FlashCopy mapping also fails in the following cases:

- You use the **prep** parameter.
- The target volume is an active remote copy primary or secondary volume.
- The FlashCopy target (and remote copy primary target) volume is offline. If this occurs, the FlashCopy mapping stops and the target volume remains offline.

Note: Maps that are `rc_controlled` are not shown in the view when this command is specified.

An invocation example

```
prestartfcconsistgrp 1
```

The resulting output:

```
No feedback
```

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

prestartfcmap

Use the **prestartfcmap** command to prepare a FlashCopy mapping so that it can be started. This command flushes the cache of any data that is destined for the source volume and forces the cache into the write-through mode until the mapping is started.

Syntax

➔ prestartfcmap 

Parameters

-restore

(Optional) Specifies the restore flag. This forces the mapping to be prepared even if the target volume is being used as a source volume in another active mapping. An active mapping is in the copying, suspended, or stopping state.

fc_map_id / fc_map_name

(Required) Specifies the name or ID of the mapping to prepare.

Description

This command prepares a single mapping for subsequent starting. The preparation step ensures that any data that resides in the cache for the source volume is first transferred to disk. This step ensures that the copy that is made is consistent with what the operating system expects on the disk.

The **restore** parameter can be used to force the mapping to be prepared even if the target volume is being used as a source volume of another active mapping. In this case, the mapping is restoring as shown in the **lsfcmap** view. If the **restore** parameter is specified when preparing a mapping where the target volume is not the source volume of another active mapping, then the parameter is ignored.

Note: To prepare a FlashCopy mapping that is part of a consistency group, you must use the **prestartfcconsistgrp** command.

The mapping must be in the `idle_or_copied` or `stopped` state before it can be prepared. When the **prestartfcmap** command is processed, the mapping enters the preparing state. After the preparation is complete, it changes to the prepared state. At this point, the mapping is ready to start.

Attention: This command can take a considerable amount of time to complete. For example, while a volume is in the prepared state, response times might increase.

This command is rejected if the target of the FlashCopy mappings is the secondary volume in a Metro Mirror, Global Mirror, or active-active relationship (so that the FlashCopy target is the remote copy secondary). Remote copy includes Metro Mirror, Global Mirror, and active-active.

Note: If the remote copy is idling or disconnected, even if the FlashCopy and remote copy are pointing to the same volume, the auxiliary volume is not necessarily the secondary volume. In this case, you can start a FlashCopy mapping.

The FlashCopy mapping also fails in the following cases:

- The remote copy is active.
- The FlashCopy target (and remote copy primary target) volume is offline. If this occurs, the FlashCopy mapping stops and the target volume remains offline.

Note: Maps that are `rc_controlled` are not shown in the view when this command is specified.

An invocation example

```
prestartfcmap 1
```

The resulting output:

```
No feedback
```

Use the **lsfcmapcandidate** command to list all of the volumes that are associated with fewer than 256 FlashCopy mappings.

lsfcmapprogress

Use the **lsfcmapprogress** command to display the progress of the background copy of a FlashCopy mapping. This information is displayed as a percentage-completed value.

lsfcmapdependentmaps

Use the **lsfcmapdependentmaps** command to display the FlashCopy mappings that depend on the user specified mapping.

lsrmvdiskdependentmaps

Use the **lsrmvdiskdependentmaps** command to display all FlashCopy mappings that must be stopped for the specified volume to be deleted.

mkfcconsistgrp

Use the **mkfcconsistgrp** command to create a new FlashCopy consistency group and identification name.

mkfcmap

Use the **mkfcmap** command to create a new FlashCopy mapping, which maps a source volume to a target volume for subsequent copying.

prestartfcconsistgrp

Use the **prestartfcconsistgrp** command to prepare a consistency group (a group of FlashCopy mappings) so that the consistency group can be started. This command flushes the cache of any data that is destined for the source volume and forces the cache into the write-through mode until the consistency group is started.

rmfcconsistgrp

Use the **rmfcconsistgrp** command to delete a FlashCopy consistency group.

rmfcmap

Use the **rmfcmap** command to delete an existing mapping.

startfcconsistgrp

Use the **startfcconsistgrp** command to start a FlashCopy consistency group of mappings. This command makes a point-in-time copy of the source volumes at the moment that the command is started.

startfcmap

Use the **startfcmap** command to start a FlashCopy mapping. This command makes a point-in-time copy of the source volume at the moment that the command is started.

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

rmfcconsistgrp

Use the **rmfcconsistgrp** command to delete a FlashCopy consistency group.

Syntax

➔ **rmfcconsistgrp** 

Parameters

-force

(Optional) Specifies that all of the mappings that are associated with a consistency group that you want to delete are removed from the group and changed to stand-alone mappings. This parameter is only required if the consistency group that you want to delete contains mappings.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

fc_consist_group_id | fc_consist_group_name

(Required) Specifies the ID or name of the consistency group that you want to delete.

Description

This command deletes the specified FlashCopy consistency group. If there are mappings that are members of the consistency group, the command fails unless you specify the **-force** parameter. When you specify the **-force** parameter, all of the mappings that are associated with the consistency group are removed from the group and changed to stand-alone mappings.

To delete a single mapping in the consistency group, you must use the **rmfcmap** command.

Note: Maps that are `rc_controlled` are not shown in the view when this command is specified.

An invocation example

```
rmfcconsistgrp fcconsistgrp1
```

The resulting output:

```
No feedback
```

Use the **startfcconsistgrp** command to start a FlashCopy consistency group of mappings. This command makes a point-in-time copy of the source volumes at the moment that the command is started.

startfcmap

Use the **startfcmap** command to start a FlashCopy mapping. This command makes a point-in-time copy of the source volume at the moment that the command is started.

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

rmfcmap

Use the **rmfcmap** command to delete an existing mapping.

Syntax

➔ **rmfcmap** 

Parameters

-force

(Optional) Specifies that the target volume is brought online. This parameter is required if the FlashCopy mapping is in the stopped state.

fc_map_id / fc_map_name

(Required) Specifies the ID or name of the FlashCopy mapping to delete. Enter the ID or name last on the command line.

Description

The **rmfcmap** command deletes the specified mapping if the mapping is in the `idle_or_copied` or `stopped` state. If it is in the `stopped` state, the **-force** parameter is required. If the mapping is in any other state, you must stop the mapping before you can delete it.

Deleting a mapping only deletes the logical relationship between the two volumes; it does not affect the volumes themselves. However, if you force the deletion, the target volume (which might contain inconsistent data) is brought back online.

If the target of the FlashCopy mapping is a member of the remote copy created, the remote copy can be affected in the following ways:

- If a stopped FlashCopy mapping is deleted and the I/O group associated with the FlashCopy mapping is suspended while this delete is being processed, then all remote copy relationships associated with the target volume of a the FlashCopy mapping that were active while the FlashCopy mapping was copying can be corrupted. You must resynchronize them next time you start the system.
- If a stopped FlashCopy mapping that has previously failed to prepare is deleted, then all remote copy relationships in the set of remote copy relationships associated with the target volume can be corrupted. You must resynchronize them next time you start the system.

Note: Remote copy includes Metro Mirror, Global Mirror, and HyperSwap.

Note: Maps that are `rc_controlled` are not shown in the view when this command is specified.

An invocation example

```
rmfcmap testmap
```

The resulting output:

```
No feedback
```

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

startfcconsistgrp

Use the **startfcconsistgrp** command to start a FlashCopy consistency group of mappings. This command makes a point-in-time copy of the source volumes at the moment that the command is started.

Syntax

➤ **startfcconsistgrp** 

Parameters

-prep

(Optional) Specifies that the designated FlashCopy consistency group be prepared prior to starting the FlashCopy consistency group. A FlashCopy consistency group must be prepared before it can be started. When you use this parameter, the system automatically issues the **prestartfcconsistgrp** command for the group that you specify.

-restore

(Optional) Specifies the restore flag. When combined with the **prep** option, this forces the consistency group to be prepared even if the target volume of one of the mappings in the consistency

group is being used as a source volume in another active mapping. An active mapping is in the copying, suspended, or stopping state.

fc_consist_group_id | fc_consist_group_name

(Required) Specifies the ID or name of the consistency group mapping to start.

Description

This command starts a consistency group, which results in a point-in-time copy of the source volumes of all mappings in the consistency group. You can combine the **restore** parameter with the **prep** parameter to force the consistency group to be prepared prior to starting, even if the target volume of one or more mappings in the consistency group is being used as a source volume of another active mapping. In this case, the mapping is restoring as shown in the **lsfcmap** view. If the **restore** parameter is specified when starting a consistency group where none of the target volumes are the source volume of another active mapping, the parameter is ignored.

If a consistency group is started and the target volume of the mapping being started has up to four other incremental FlashCopy mappings using the target, the incremental recording is left on. If there are more than four other incremental FlashCopy mappings using the target volume, the incremental recording for all of these mappings is turned off until they are restarted.

Note: The **startfcconsistgrp** command can take some time to process particularly if you have specified the **prep** parameter. If you use the **prep** parameter, you give additional processing control to the system because the system must prepare the mapping before the mapping is started. If the prepare process takes too long, the system completes the prepare but does not start the consistency group. In this case, error message CMMVC6209E displays. To control the processing times of the **prestartfcconsistgrp** and **startfcconsistgrp** commands independently of each other, do not use the **prep** parameter. Instead, first issue the **prestartfcconsistgrp** command, and then issue the **startfcconsistgrp** command to start the copy.

This command is rejected if the target of the FlashCopy mapping in the specified consistency group is the secondary volume in a remote copy relationship (so that the FlashCopy target is the remote copy secondary).

Note: If the remote copy is idling or disconnected, even if the FlashCopy and remote copy are pointing to the same volume, the auxiliary volume is not necessarily the secondary volume. In this case, you can start a FlashCopy mapping.

The FlashCopy mapping also fails in the following cases, if the target of the FlashCopy mapping in the specified consistency group is the primary volume in a remote copy relationship (so that the FlashCopy target is the remote copy primary target):

- The remote copy is active.
- The FlashCopy target (and remote copy primary target) volume is offline. If this occurs, the FlashCopy mapping stops and the target volume remains offline.

Maps that are **rc_controlled** are not shown in the view when this command is specified.

If any source volumes in the FlashCopy consistency group are in an active-active relationship, the group can only be started if the information on all those source volumes current, or an older copy to which access has been provided by specifying:

```
stopprcrelationship -access
```

A current volume in an active-active relationship is the primary copy, or the secondary copy when the relationship's state is **consistent_synchronized**.

An invocation example

```
startfcconsistgrp -prep 2
```

The resulting output:

No feedback

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

startfcmap

Use the **startfcmap** command to start a FlashCopy mapping. This command makes a point-in-time copy of the source volume at the moment that the command is started.

Syntax

Parameters

-prep

(Optional) Specifies that the designated mapping be prepared prior to starting the mapping. A mapping must be prepared before it can be started. When you use this parameter, the system automatically issues the **prestartfcmap** command for the group that you specify.

Note: If you have already used the **prestartfcmap** command, you cannot use the **-prep** parameter on the **startfcmap** command; the command fails. However, if the FlashCopy has successfully prepared before, the **startfcmap** command succeeds.

-restore

(Optional) Specifies the restore flag. When combined with the **prep** option, this forces the mapping to be prepared even if the target volume is being used as a source volume in another active mapping. An active mapping is in the copying, suspended, or stopping state.

fc_map_id / fc_map_name

(Required) Specifies the ID or name of the mapping to start.

Description

This command starts a single mapping, which results in a point-in-time copy of the source volume. You can combine the **restore** parameter with the **prep** parameter to force the mapping to be prepared prior to starting, even if the target volume is being used as a source volume of another active mapping. In this case, the mapping is restoring as shown in the **lsfcmap** view. If the **restore** parameter is specified when starting a mapping where the target volume is not the source volume of another active mapping, the parameter is ignored and the mapping is not restoring as shown in the **lsfcmap** view.

If a mapping is started and the target volume of the mapping being started has up to four other incremental FlashCopy mappings using the target, the incremental recording is left on. If there are more than four other incremental FlashCopy mappings using the target volume, the incremental recording for all of these mappings is turned off until they are restarted.

Note: The **startfcmap** command can take some time to start, particularly if you use the **prep** parameter. If you use the **prep** parameter, you give additional starting control to the system. The system must prepare the mapping before the mapping is started. To keep control when the mapping starts, you must issue the **prestartfcmap** command before you issue the **startfcmap** command.

This command is rejected if the target of the FlashCopy mapping is the secondary volume in a Metro Mirror or Global Mirror relationship (so that the FlashCopy target is the remote copy secondary).

Note: If the remote copy is idling or disconnected, even if the FlashCopy and remote copy are pointing to the same volume, the auxiliary volume is not necessarily the secondary volume. In this case, you can start a FlashCopy mapping.

The FlashCopy mapping also fails in the following cases, if the target of the FlashCopy mapping is the primary volume in a Metro Mirror or Global Mirror relationship (so that the FlashCopy target is the remote copy primary):

- The remote copy is active.
- The FlashCopy target (and remote copy primary target) volume is offline. If this occurs, the FlashCopy mapping stops and the target volume remains offline.

Maps that are `rc_controlled` are not shown in the view when this command is specified.

Remember: If the source volume is in an active-active relationship then the FlashCopy mapping can only be started if the information on the source volume is current, or an older copy to which access has been provided by specifying:

```
stoprcrelationship -access
```

A current volume in an active-active relationship is the primary copy, or the secondary copy when the relationship's state is `consistent_synchronized`.

An invocation example

```
startfcmap -prep 2
```

The resulting output:

```
No feedback
```

Use the **rmfcmap** command to delete an existing mapping.

startfcconsistgrp

Use the **startfcconsistgrp** command to start a FlashCopy consistency group of mappings. This command makes a point-in-time copy of the source volumes at the moment that the command is started.

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

Syntax

➡ stopfcconsistgrp  *fc_consist_group_id_or_name* ⇠

Parameters

-force

(Optional) Specifies that all processing that is associated with the mappings of the designated consistency group be stopped immediately.

Note: When you use this parameter, all FlashCopy mappings that depend on the mappings in this group (as listed by the **lsfcmapdependentmaps** command) are also stopped.

If the **-force** parameter is not specified, the command is rejected if the target volume of the FlashCopy consistency group is the primary in a relationship that is mirroring I/O:

- consistent_synchronized
- consistent_copying
- inconsistent_copying

If the **-force** parameter is specified, any Metro Mirror or Global Mirror relationships associated with the target volumes of the FlashCopy mappings in the specified consistency group stops. If a remote copy relationship associated with the target was mirroring I/O when the map was copying, it might lose its difference recording capability and require a full resynchronization upon a subsequent restart.

-split

(Optional) Breaks the dependency on the source volumes of any mappings that are also dependent on the target volume. This parameter can only be specified when stopping a consistency group where all maps in the group have progress of 100 as shown by the **lsfcmap** command.

fc_consist_group_id_or_name

(Required) Specifies the name or ID of the consistency group that you want to stop.

Description

This command stops a group of mappings in a consistency group. If the copy process is stopped, the target disks become unusable unless they already contain complete images of the source. Disks that contain complete images of the source have a progress of 100, as indicated in the **lsfcmap** command output. The target volume is reported as offline if it does not contain a complete image. Before you can access this volume, the group of mappings must be prepared and restarted.

If the consistency group is in the `idle_or_copied` state, the `stopfcconsistgrp` command has no effect and the consistency group stays in the `idle_or_copied` state.

Note: Prior to SAN Volume Controller 4.2.0, the **stopfcconsistgrp** command always caused the consistency group to go to the stopped state, taking the target volumes offline.

The **split** option can be used when all of the maps in the group have progress of 100. It removes the dependency of any other maps on the source volumes. It might be used prior to starting another FlashCopy consistency group whose target disks are the source disks of the mappings being stopped. Once the consistency group has been stopped with the **split** option, the other consistency group could then be started without the **restore** option.

Note: Maps that are `rc_controlled` are not shown in the view when this command is specified.

An invocation example

```
stopfcconsistgrp testmapone
```

The resulting output

```
No feedback
```

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

stopfcmap

Use the **stopfcmap** command to stop all processing that is associated with a FlashCopy mapping that is in one of the following processing states: prepared, copying, stopping, or suspended.

Syntax

```
➤ stopfcmap { -force | -split } fc_map_id_or_name ➤
```

Parameters

-force

(Optional) Specifies that all processing that is associated with the designated mapping stops immediately.

Note: When you use this parameter, all FlashCopy mappings that depend on this mapping (as listed by the **lsfcmapdependentmaps** command) are also stopped.

If the **-force** parameter is not specified, the command is rejected if the target volume of the FlashCopy mapping is the primary in a relationship that is mirroring I/O:

- consistent_synchronized
- consistent_copying
- inconsistent_copying

If the **-force** parameter is specified for a FlashCopy mapping whose target volume is also in a Metro Mirror or Global Mirror relationship, the relationship stops. A remote copy relationship associated with the target that is mirroring I/O while the map is copying might lose its difference recording capability. In this case, a full resynchronization might be necessary during a subsequent restart.

-split

(Optional) Breaks the dependency on the source volume of any mappings that are also dependent on the target disk. Specify this parameter only when you are stopping a map with a progress of 100 as shown by the **lsfcmap** command.

fc_map_id_or_name

(Required) Specifies the name or ID of the mapping to stop.

Description

This command stops a single mapping. If the copy process is stopped, the target disk becomes unusable unless it already contained a complete image of the source. A complete image is indicated by a map with a progress of 100, as shown by the **lsfcmap** command. For incomplete mappings, prepare and reprocess the mapping before you use the target disk.

Only stand-alone mappings can be stopped with the **stopfcmap** command. Stop mappings that belong to a consistency group with the **stopfcconsistgrp** command.

If the mapping is in the `idle_or_copied` state, the **stopfcmap** command has no effect and the mapping stays in the `idle_or_copied` state.

Note: Before SAN Volume Controller 4.2.0, the **stopfcmap** command always changed the mapping state to stopped and took the target volume offline. This change can break scripts that depend on the previous behavior.

The **split** option can be used when the mapping has progress of 100. It removes the dependency of any other mappings on the source volume. It might be used before you start another FlashCopy mapping

whose target disk is the source disk of the mapping that you are stopping. After the mapping stops by using the **split** option, you can start the other mapping without the **restore** option.

Note: Maps that are `rc_controlled` are not shown in the view when this command is specified.

Remember: A source volume that is in an active-active relationship stops the FlashCopy mapping only when information on the source volume is current. Alternatively, you can stop the mapping after you provide an older accessible copy with the following command:

```
stoprcrelationship -access
```

A current volume in an active-active relationship is the primary copy, or the secondary copy when the relationship's state is `consistent_synchronized`.

An invocation example

```
stopfcmap testmapone
```

The resulting output

```
No feedback
```

[chfcconsistgrp](#)

Use the **chfcconsistgrp** command to change the name of a consistency group or mark the group for auto-deletion. You can also change the ownership group.

[chfcmap](#)

Use the **chfcmap** command to modify attributes of an existing mapping.

[lsfcconsistgrp](#)

Use the **lsfcconsistgrp** command to display a concise list or a detailed view of FlashCopy consistency groups that are visible to the system. This information is useful for tracking FlashCopy consistency groups.

[lsfcmap](#)

Use the **lsfcmap** command to generate a list that contains concise information about all of the FlashCopy mappings that are visible to the system, or detailed information for a single FlashCopy mapping.

[lsfcmapcandidate](#)

Use the **lsfcmapcandidate** command to list all of the volumes that are associated with fewer than 256 FlashCopy mappings.

[lsfcmapprogress](#)

Use the **lsfcmapprogress** command to display the progress of the background copy of a FlashCopy mapping. This information is displayed as a percentage-completed value.

[lsfcmapdependentmaps](#)

Use the **lsfcmapdependentmaps** command to display the FlashCopy mappings that depend on the user specified mapping.

[lsrmvdiskdependentmaps](#)

Use the **lsrmvdiskdependentmaps** command to display all FlashCopy mappings that must be stopped for the specified volume to be deleted.

[mkfcconsistgrp](#)

Use the **mkfcconsistgrp** command to create a new FlashCopy consistency group and identification name.

[mkfcmap](#)

Use the **mkfcmap** command to create a new FlashCopy mapping, which maps a source volume to a target volume for subsequent copying.

prestartfcconsistgrp

Use the **prestartfcconsistgrp** command to prepare a consistency group (a group of FlashCopy mappings) so that the consistency group can be started. This command flushes the cache of any data that is destined for the source volume and forces the cache into the write-through mode until the consistency group is started.

prestartfcmap

Use the **prestartfcmap** command to prepare a FlashCopy mapping so that it can be started. This command flushes the cache of any data that is destined for the source volume and forces the cache into the write-through mode until the mapping is started.

rmfcconsistgrp

Use the **rmfcconsistgrp** command to delete a FlashCopy consistency group.

rmfcmap

Use the **rmfcmap** command to delete an existing mapping.

startfcconsistgrp

Use the **startfcconsistgrp** command to start a FlashCopy consistency group of mappings. This command makes a point-in-time copy of the source volumes at the moment that the command is started.

startfcmap

Use the **startfcmap** command to start a FlashCopy mapping. This command makes a point-in-time copy of the source volume at the moment that the command is started.

stopfcconsistgrp

Use the **stopfcconsistgrp** command to stop all processing that is associated with a FlashCopy consistency group that is in one of the following processing states: prepared, copying, stopping, or suspended.

Chapter 16. Host commands

Use the host commands to work with host objects on your system.

addhostclustermember

Use the **addhostclustermember** command to add a host object to a host cluster.

Syntax

➔ **addhostclustermember** **-host** *host_id_list* *hostcluster_id* *host_name_list* *hostcluster_name* ➔

Parameters

-host *host_id_list* / *host_name_list*

(Optional) Specifies the host (by ID or name) to add to the host cluster.

hostcluster_id / *hostcluster_name*

(Required) Specifies (by ID or name) the host cluster that the host object is added to. The value for the ID must be a number and the value for the name must be an alphanumeric string.

Description

This command adds a host object to a host cluster. All hosts in a host cluster must use the same protocol (SCSI or NVMe).

When you add a host object to a host cluster, shared mappings are created. For example, if any host mappings match a host cluster mapping that is part of the same volume on the same Small Computer System Interface (SCSI) logical unit number (LUN) - with the same I/O groups - the host cluster assumes control of the mapping (which makes it a shared mapping).

Note: A host cannot be added to a host cluster if both have their individual throttling specifications defined. However, if either the host or host cluster throttling specification is present, the command succeeds.

Any mappings that do not match the shared host cluster mappings are managed by the host as private mappings.

Note: New mappings must not conflict with a shared mapping on a host system. The command fails when there are shared mappings that conflict with the host's private mappings. This includes either:

- A volume that is being mapped - but with different SCSI LUNs
- The host that has a different volume mapped but with the same SCSI LUN as a shared mapping of the host cluster

An invocation example that adds host 0 to host cluster 4

```
addhostclustermember -host 0 4
```

The resulting output:

```
No feedback
```

An invocation example that adds hosts 0, 1, and 4 to host cluster 4

```
addhostclustermember -host 0:1:4 4
```

The resulting output:

No feedback

[addhostiogr](#)

Use the **addhostiogr** command to map I/O groups to an existing host object.

[addhostport](#)

Use the **addhostport** command to add worldwide port names (WWPNs), Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) to an existing host object.

[chhost](#)

Use the **chhost** command to change the name or type of a host object. This command does not affect any existing host mappings.

[chhostcluster](#)

Use the **chhostcluster** to change the name, type, or site of a host cluster object that is part of a host cluster.

[lshost](#)

Use the **lshost** command to generate a list with concise information about all the hosts visible to the system and detailed information about a single host.

[lshostcluster](#)

Use the **lshostcluster** command to generate a list with concise information about all the host clusters that are defined on the system or detailed information about a single host cluster.

[lshostclustermember](#)

Use the **lshostclustermember** command to generate a list with host information for hosts that belong to the specified host cluster.

[lshostclustervolumemap](#)

Use the **lshostclustervolumemap** command to display a list of volumes that are mapped to all host clusters (or to a specific host cluster).

[lshostiogr](#)

Use the **lshostiogr** command to display a list the I/O groups that are associated with a specified host.

[lshostiplogin](#)

Use the **svcinfo lshostiplogin** command to list the login session type and other details for hosts that are identified by their iSCSI Qualified Name (IQN) and logged in to Ethernet ports that are configured with IP addresses.

[lsscsiath](#)

Use the **lsscsiath** command to list the Challenge Handshake Authentication Protocol (CHAP) secret that is configured for authenticating an entity to the system.

[mkhost](#)

Use the **mkhost** command to create a logical host object.

[mkhostcluster](#)

Use the **mkhostcluster** command to create a host cluster object.

[mkvolumehostclustermap](#)

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

[rmhost](#)

Use the **rmhost** command to delete a host object.

[rmhostcluster](#)

Use the **rmhostcluster** command to remove a host cluster.

[rmhostclustermember](#)

Use the **rmhostclustermember** command to remove a host from a host cluster object.

[rmvolumehostclustermap](#)

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

[rmhostiogrp](#)

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

[rmhostport](#)

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

addhostiogrp

Use the **addhostiogrp** command to map I/O groups to an existing host object.

Syntax

➔ **addhostiogrp** 

Parameters

-iogrp *iogrp_list*

(Required if you do not use **-iogrpall**) Specifies a colon-separated list of one or more I/O groups that must be mapped to the host. You cannot use this parameter with the **-iogrpall** parameter.

-iogrpall

(Required if you do not use **-iogrp**) Specifies that all the I/O groups must be mapped to the specified host. You cannot use this parameter with the **-iogrp** parameter.

host_id* / *host_name

(Required) Specifies the host to which the I/O groups must be mapped, either by ID or by name.

Description

This command allows you to map the list of I/O groups to the specified host object.

An invocation example

```
addhostiogrp -iogrpall testhost
```

The resulting output:

```
No feedback
```

Use the **chhost** command to change the name or type of a host object. This command does not affect any existing host mappings.

[chhostcluster](#)

Use the **chhostcluster** to change the name, type, or site of a host cluster object that is part of a host cluster.

lshost

Use the **lshost** command to generate a list with concise information about all the hosts visible to the system and detailed information about a single host.

lshostcluster

Use the **lshostcluster** command to generate a list with concise information about all the host clusters that are defined on the system or detailed information about a single host cluster.

lshostclustermember

Use the **lshostclustermember** command to generate a list with host information for hosts that belong to the specified host cluster.

lshostclustervolumemap

Use the **lshostclustervolumemap** command to display a list of volumes that are mapped to all host clusters (or to a specific host cluster).

lshostiogr

Use the **lshostiogr** command to display a list the I/O groups that are associated with a specified host.

lshostiplogin

Use the **svcinfo lshostiplogin** command to list the login session type and other details for hosts that are identified by their iSCSI Qualified Name (IQN) and logged in to Ethernet ports that are configured with IP addresses.

lsiscsiauth

Use the **lsiscsiauth** command to list the Challenge Handshake Authentication Protocol (CHAP) secret that is configured for authenticating an entity to the system.

mkhost

Use the **mkhost** command to create a logical host object.

mkhostcluster

Use the **mkhostcluster** command to create a host cluster object.

mkvolumehostclustermap

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

rmhost

Use the **rmhost** command to delete a host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogr

Use the **rmhostiogr** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

addhostport

Use the **addhostport** command to add worldwide port names (WWPNs), Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) to an existing host object.

Syntax

Parameters

-saswwpn wwpn_list

(Required if you do not use **-iscsiname**, **-fcwwpn**, or **-nqn**.) Specifies a list of Serial Attached SCSI (SAS) WWPNs with a 16-character hexadecimal string.

-fcwwpn wwpn_list

(Required if you do not use **-iscsiname**, **-saswwpn**, or **-nqn**.) Specifies a list of Fibre Channel (FC) WWPNs with a 16-character hexadecimal string.

-iscsiname iscsi_name_list

(Required if you do not use **-fcwwpn**, **-saswwpn**, or **-nqn**.) Specifies the comma-separated list of iSCSI names to add to the host. At least one WWPN or iSCSI name must be specified. You cannot use this parameter with the **-fcwwpn** or **-saswwpn** parameter.

-nqn nqn_list

(Required if you do not use **-fcwwpn**, **-saswwpn**, or **-iscsiname**.) Specifies the comma-separated list of NVMe Qualified Names (NQN) to add to the host. The host protocol must be **nvme** to use this parameter.

-force

(Optional) Specifies that the list of ports be added to the host without the validation of any WWPNs or iSCSI names.

host_id / host_name

(Required) Specifies the host object to add ports to, either by ID or by name.

Description

This command adds a list of host bus adapter (HBA) WWPNs, iSCSI names, or NQN to the specified host object. Any volumes that are mapped to this host object automatically map to the new ports.

Note: The host port can only be added if it is compatible with the protocol of the host (SCSI can have all port types except NQN, NVMe can have only NQN).

Only WWPNs that are logged-in unconfigured can be added. For a list of candidate WWPNs, use the **lssasportcandidate** or **lsfcportcandidate** command.

Some HBA device drivers do not log in to the fabric until they can recognize target logical unit numbers (LUNs). Because they do not log in, their WWPNs are not recognized as candidate ports. You can specify the **force** parameter with the **addhostport** command to stop the validation of the WWPN list.

Note: When all I/O groups are removed from an iSCSI host, you cannot add a port to the iSCSI host until you map the iSCSI host to at least one I/O group. After you map the iSCSI host to at least one I/O group, resubmit the **addhostport** command. After you add the port to the host, you must create a host authentication entry using the **chhost** command.

The **addhostport** command fails if the:

- Host is mapped to a volume with more than one I/O group in the access set and the host port you add is an Internet Small Computer System Interface (iSCSI) name
- Port being added is from a host system that does not support volumes mapped from multiple I/O groups

An invocation example

```
addhostport -saswwpn 210100E08B251DD4 host1
```

The resulting output:

```
No feedback
```

An invocation example

```
addhostport -fcwwpn 210100E08B251EE6 host1
```

The resulting output:

```
No feedback
```

An invocation example

```
addhostport -iscsiname iqn.localhost.hostid.7f000001 mchost13
```

The resulting output:

```
No feedback
```

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

rmhost

Use the **rmhost** command to delete a host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

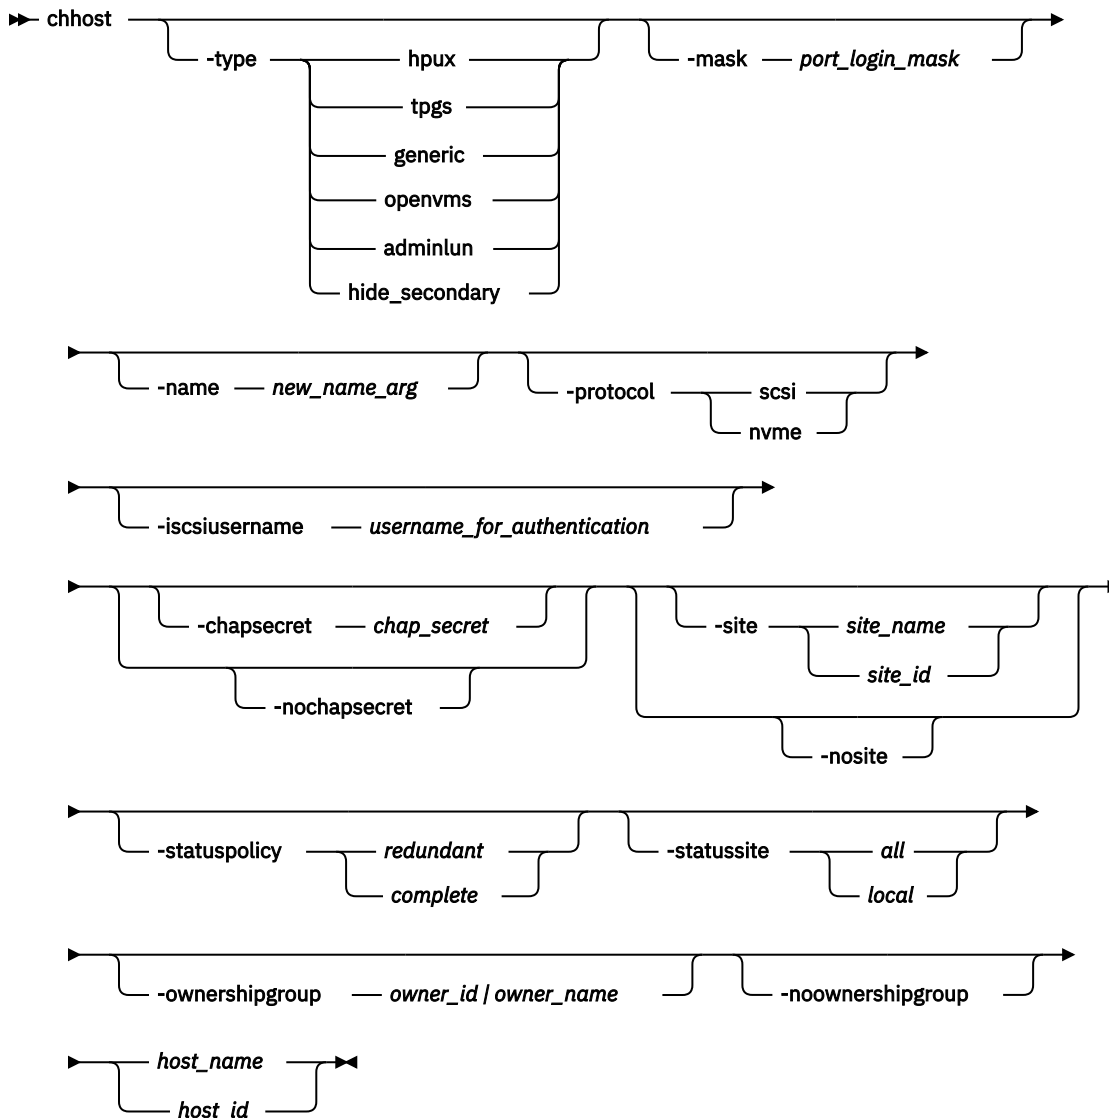

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

chhost

Use the **chhost** command to change the name or type of a host object. This command does not affect any existing host mappings.

Syntax

Parameters

-type hpux | tpgs | generic | openvms | adminlun | hide_secondary

(Optional) Specifies the type of host. The following values are the available host types:

- generic indicates the default.
- tpgs indicates when target port information changes (extra unit attentions are given to the host).
- openvms indicates OpenVMS.
- adminlun indicates virtual volumes, which are enabled on the host.
- hpux indicates HP-UX firmware.

- `hide_secondary` indicates that all remote copy relationship secondary volumes are unavailable to the host.

-name *new_name_arg*

```
-protocol scsi | nvme
```

- No volumes are mapped to the host.
- No ports are defined on the host.
- The host type is compatible with the new protocol. A host that uses the NVMe protocol must be of type **generic**.

-iscsiusername *username_for_authentication*

-chapsecret *chap_secret*

-nochapsecret

-site *site_name* / *site_id*

Note: If the host is mapped to a volume that is in an active-active relationship (HyperSwap), you cannot specify **-nosite**.

-statuspolicy redundant / complete

- Complete connectivity is where online host status indicates complete connectivity, with every host port that is logged in to every node through which that host can access volumes, and degraded host status indicates one or more of these nodes does not have a login.
- Redundant connectivity calculation is where online host status indicates redundant connectivity, where enough host ports are logged in to enough nodes such that the removal of a single node or a single host port allows that host to access all of its volumes. In addition, there must be the same total login count from the host to each node within an I/O group. Degraded host status indicates non-redundant connectivity, in which a single point of failure prevents a host from accessing at least some of its volumes, or there is no single point of failure but the total login count from the host to each node within an I/O group is not the same.

The default value is *redundant*.

-statussite *all* / *local*

(Optional) Specifies whether *all* sites or only the *local* host site connectivity is used to determine online status. *local* is only applicable in a dual site topology for a host with a valid site. The default value is *all*.

-ownershipgroup *owner_id* / *owner_name*

(Optional) The name or ID of the ownership group to which the object is being added.

-noownershipgroup

(Optional) If specified, the object is removed from the ownership group to which it belongs.

host_name* / *host_id

(Required) Specifies the host object to modify, either by ID or by current name.

Description

This command can change the name of the specified host to a new name, or it can change the type of host. This command does not affect any of the current host mappings.

The port mask applies to logins from the host initiator port that are associated with the host object. For each login between a host bus adapter (HBA) port and node port, the node examines the port mask that is associated with the host object for which the host HBA is a member and determines whether access is allowed or is denied. If access is denied, the node responds to SCSI commands as if the HBA port is unknown.

Note: When all I/O groups are removed from an iSCSI host, the **lsiscsiauth** command does not display the authentication entry for that host. Use the **addhostiogrp** command to map the iSCSI host to at least one I/O group, and then use the **addhostport** command to add the iSCSI port into it. You must also add authentication for that host by using the **chhost** command with either the **chapsecret** or **nochapsecret** parameter.

Note: If the host is contained within a host cluster, you cannot change the ownership. The host is observing the ownership of the host cluster.

An invocation example

```
chhost -name testhostlode -mask 111111101101 hostone
```

The following output is displayed:

```
No feedback
```

An invocation example

```
chhost -type openvms 0
```

The following output is displayed:

```
No feedback
```

An invocation example

```
chhost -site site1 host3
```

The following output is displayed:

```
No feedback
```

An invocation example changing the ownership of a host

```
chhost -ownershipgroup 2 myhost
```

The following output is displayed:

```
No feedback
```

An invocation example moving the host to no ownership

```
chhost -noownershipgroup myhost
```

The following output is displayed:

```
No feedback
```

[rmhostiogrp](#)

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

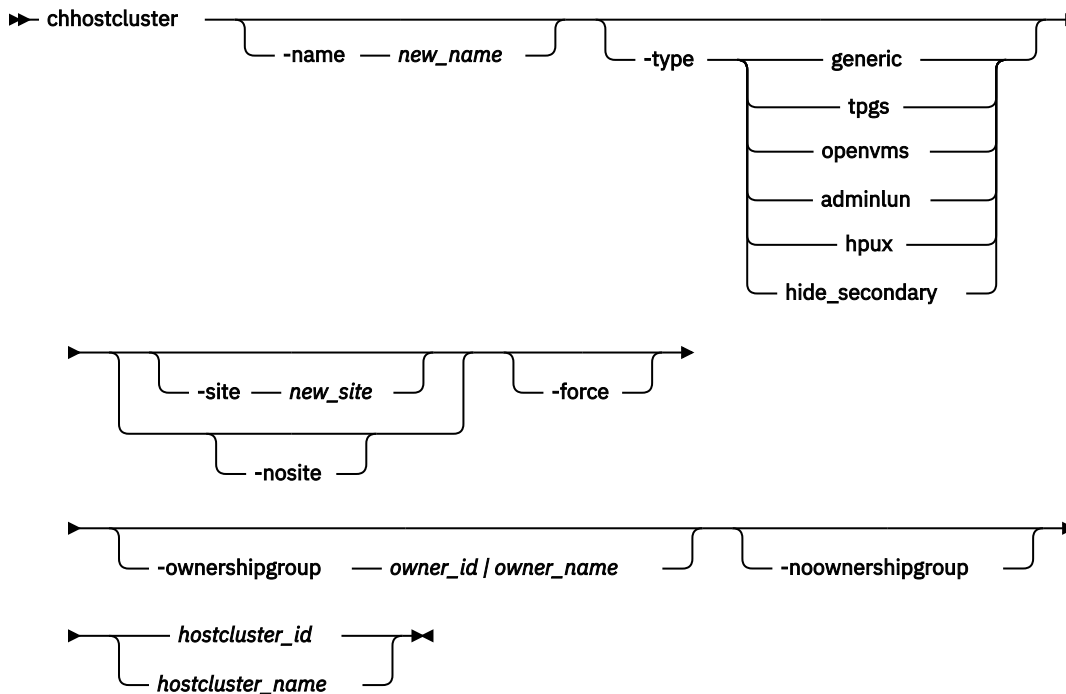

[rmhostport](#)

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

chostcluster

Use the **chostcluster** to change the name, type, or site of a host cluster object that is part of a host cluster.

Syntax

Parameters

-name *new_name*

(Optional) Specifies a name for a host cluster object. The value must be an alphanumeric string.

-type *new_type*

(Optional) Changes the type of the all hosts in the host cluster. The following values are available host types:

- *generic* indicates the default.
- *tpgs* indicates when target port information changes, extra unit attentions are given to the host.
- *openvms* indicates OpenVMS.
- *adminlun* indicates virtual volumes, which are enabled on the host.
- *hpux* indicates HP-UX firmware.
- *hide_secondary* indicates that all remote copy relationship secondary volumes are unavailable to the host.

Note: NVMe host types cannot be changed.

-site *new_site*

(Optional) Changes the site for all hosts in the host cluster. The value must be an alphanumeric string and the default is *site0* (meaning there is no site).

-nosite

(Optional) Resets the site value.

-force

(Optional) Specify this parameter to change the host cluster's site and also change a site for at least one host in that host cluster. You do not have to specify this parameter if you are changing site 0.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

-ownershipgroup *owner_id* / *owner_name*

(Optional) The name or ID of the ownership group to which the object is being added.

-noownershipgroup

(Optional) If specified, the object is removed from the ownership group to which it belongs.

hostcluster_id* / *hostcluster_name

(Required) Specifies (by ID or name) the host cluster object to change. The value for the ID must be a number and the value for the name must be an alphanumeric string.

Description

This command changes the name, type, or a site on a host cluster object.

If you assign a host to a site and it is not specified as site0, you must use **-force** to change it.

Important: Do not specify **-site site0**, instead use **-nosite**.

If you specify the **-site** and **-type** parameters, the site and type properties that are changed are not attributes of the host cluster object. They are properties of the individual hosts that are members of the host cluster. These properties can be modified by using the **chhostcluster** command to change the attribute values on every host in the host cluster simultaneously (rather than modifying each host separately).

An invocation example that changes settings of host cluster *hostcluster0*

```
chhostcluster -name myhostcluster hostcluster0
```

The following detailed output is displayed:

```
No feedback
```

An invocation example that changes site of every host in host cluster 2

The hosts are currently in site 0 or in site1.

```
chhostcluster -site site1 2
```

The following detailed output is displayed:

```
No feedback
```

An invocation example that changes name of *hostcluster0*

All host sites are set to site0, which is the default. One host is not currently in site 0.

```
chhostcluster -name jvardy1 -nosite -force hostcluster0
```

The following detailed output is displayed:

```
No feedback
```

An invocation example changing the ownership of a host cluster

```
chhostcluster -ownershipgroup 2 myhostcluster
```

The following output is displayed:

```
No feedback
```

An invocation example moving the host cluster to no ownership

```
chhostcluster -noownershipgroup myhostcluster
```

The following output is displayed:

```
No feedback
```

Use the **addhostclustermember** command to add a host object to a host cluster.

[addhostiogrp](#)

Use the **addhostiogrp** command to map I/O groups to an existing host object.

[addhostport](#)

Use the **addhostport** command to add worldwide port names (WWPNs), Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) to an existing host object.

[chhost](#)

Use the **chhost** command to change the name or type of a host object. This command does not affect any existing host mappings.

[lshost](#)

Use the **lshost** command to generate a list with concise information about all the hosts visible to the system and detailed information about a single host.

[lshostcluster](#)

Use the **lshostcluster** command to generate a list with concise information about all the host clusters that are defined on the system or detailed information about a single host cluster.

[lshostclustermember](#)

Use the **lshostclustermember** command to generate a list with host information for hosts that belong to the specified host cluster.

[lshostclustervolumemap](#)

Use the **lshostclustervolumemap** command to display a list of volumes that are mapped to all host clusters (or to a specific host cluster).

[lshostiogrp](#)

Use the **lshostiogrp** command to display a list the I/O groups that are associated with a specified host.

[lshostiplogin](#)

Use the **svcinfo lshostiplogin** command to list the login session type and other details for hosts that are identified by their iSCSI Qualified Name (IQN) and logged in to Ethernet ports that are configured with IP addresses.

[lsiscsiauth](#)

Use the **lsiscsiauth** command to list the Challenge Handshake Authentication Protocol (CHAP) secret that is configured for authenticating an entity to the system.

[mkhost](#)

Use the **mkhost** command to create a logical host object.

[mkhostcluster](#)

Use the **mkhostcluster** command to create a host cluster object.

[mkvolumehostclustermap](#)

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

rmhost

Use the **rmhost** command to delete a host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

lshost

Use the **lshost** command to generate a list with concise information about all the hosts visible to the system and detailed information about a single host.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are returned. If a capacity is specified, the units must also be included.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the SAN Volume Controller command-line interface (CLI):

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard character, you must enclose the filter entry within double quotation marks (" "), as follows: `lshost -filtervalue "name=md*"`

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data exists to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

object_id / object_name

(Optional) Specifies the name or ID of an object. When you use this parameter, the detailed view of the specific object is returned and any value that is specified by the **-filtervalue** parameter is ignored. If you do not specify the *object_id / object_name* parameter, the concise view of all objects that match the filtering requirements that are specified by the **-filtervalue** parameter are displayed.

-filtervalue?

(Optional) Specifies that you want your report to display any or all of the list of valid filter attributes. The valid filter attributes for the **lshost** command are:

- **host_cluster_id**
- **host_cluster_name**
- **host_name**
- **host_id**
- **id**
- **iogrp_count**
- **name**
- **port_count**
- **site_id**
- **site_name**
- **status**
- **type**
- **protocol**

Description

This command returns a concise list or a detailed view of hosts visible to the system.

For Fibre Channel (FC) ports, the *node_logged_in_count* field provides the number of nodes that the host port is logged in to. For Internet Small Computer System Interface (iSCSI) ports, the *node_logged_in_count* field provides the number of iSCSI sessions from the host iSCSI qualified name (IQN).

You can map an iSCSI host to volumes that are accessible through multiple I/O groups. iSCSI hosts can access volumes that are accessible through multiple I/O groups (and single I/O groups). An iSCSI host that is mapped to a volume accessible through multiple I/O groups is *online* if it has at least one active iSCSI session with each I/O group of the access set. If volumes are not mapped to an iSCSI host, it is *degraded*.

The following list provides the different states for a fabric attach FC host port:

active

The host port is active if all nodes with volume mappings have a login for the specified worldwide port name (WWPN) and at least one node received SCSI commands from the WWPN within the last 5 minutes.

degraded

The host port is degraded if one or more nodes with volume mappings do not have a login for the specified WWPN.

inactive

The host port is inactive if all the nodes with volume mappings have a login for the specified WWPN but no nodes see any Small Computer System Interface (SCSI) commands from the WWPN within the last 5 minutes.

offline

The host port is offline if one or more input/output (I/O) groups with volume mappings do not have a login for the specified WWPN.

The following list provides the different states for a direct attach FC host port:

active

The host port is active if a node has a login for the specified WWPN and the node receives SCSI commands from the WWPN within the last 5 minutes.

inactive

The host port is inactive if all the nodes with volume mappings have a login for the specified WWPN but no nodes see any Small Computer System Interface (SCSI) commands from the WWPN within the last 5 minutes.

offline

The host port is offline if no login exists for the specified WWPN.

If a host does not have any volume mappings, it is reported as offline or inactive.

The following list provides the different states for a fabric attach NVMe/FC host port:

active

The host port is active if all nodes with volume mappings have a login for the specified NVMe Qualified Name (NQN) and at least one node has received NVMe commands from the NQN within the last 5 minutes.

degraded

The host port is degraded if one or more nodes with volume mappings do not have a login for the specified NQN.

inactive

The host port is inactive if all the nodes with volume mappings have a login for the specified NQN but no nodes have seen any NVMe commands from the NQN within the last 5 minutes.

offline

The host port is offline if one or more input/output (I/O) groups with volume mappings do not have a login for the specified NQN.

Note: The **lshost** command presents a list of host HBA ports that are logged in to nodes. However, situations exist when the information presented can include host HBA ports that are no longer logged in or even part of the SAN fabric. For example, a host HBA port is unplugged from a switch, but **lshost** still shows the WWPN logged in to all nodes. If this action occurs, the incorrect entry is removed when another device is plugged in to the same switch port that previously contained the removed host HBA port.

The following list provides the different states for a specified `iscsiname`:

active

The `iscsiname` is active if all I/O groups with volume mappings have at least one associated iSCSI session for the specified `iscsiname`.

inactive

The `iscsiname` is inactive if the host has no volume mappings but at least one iSCSI session for the specified `iscsiname` is present.

offline

The `iscsiname` is offline if volumes with access to one or more I/O groups are mapped to a specified `iscsiname` that has no associated iSCSI or iSER sessions on all related I/O groups.

The following list provides the different states for `host_status`:

online

The host has full connectivity. A host that uses just one style of connectivity is online if it uses one of these types:

Fibre Attach Fibre Channel (FAFC)

Every port is active or inactive, and is logged in to every online node in each I/O group in which the host has volume mappings.

Direct Attach Fibre Channel (DAFC)

The host has an active or inactive login to every node in I/O groups to which the host has volume mappings.

Internet Small Computer System Interface (iSCSI)

The host has an iSCSI session with each I/O group with which the host has volume mappings.

NVMe over Fibre Channel (FC-NVMe)

All host NQNs have NVMe associations with every online node in each I/O group in which the host has volume mappings.

offline

The host has no connectivity. The reason might be because the host is powered off and is not on.

Remember: If an iSCSI host is only logged in to I/O groups for which it is not configured, the associated host object status is `offline`.

degraded

The host is not fully connected, which might be introduced by a configuration error or a hardware failure. It can cause a loss of access during any planned maintenance activity and must be corrected as soon as possible.

Remember: An iSCSI host that has no mapped volumes is degraded if it is logged in to some, but not all, of the I/O groups to which it belongs.

mask

The Fibre Channel (FC) I/O ports (which exist on a node) hosts can access.

This table shows the possible outputs:

Table 98. <i>lshost</i> output	
Attribute	Description
id	Indicates the unique host ID. The value is an alphanumeric value.
name	Indicates the unique host name. The value is an alphanumeric string.
port_count	Indicates the number of ports.
type	Indicates the host type.
mask	Indicates the mask value with a 64-bit binary string.
iogrp_count	Indicates the number of I/O groups.
status	Indicates whether the host is online or offline.
protocol	Indicates whether the host uses <code>scsi</code> or <code>nvme</code> to access the storage.
WWPN	Indicates the worldwide port name (WWPN) with a 16-character hexadecimal string.
SAS_WWPN	Indicates the serial-attached SCSI (SAS) WWPN with a 16-character hexadecimal string.
nqn	Indicates the NVMe Qualified Name.

Table 98. **lshost** output (continued)

Attribute	Description
node_logged_in_count	Indicates the number of nodes the WWPN or NQN is logged in to.
state	Indicates the state of the SAS WWPN login. The values are: <ul style="list-style-type: none"> • offline • inactive • active
sas_wwpn_count	Indicates the number of configured SAS WWPNs.
nqn_count	Indicates the number of NVMe NQN ports assigned to the host.
site_id	Identifies the site ID for the host. The values are 1, 2, or blank.
site_name	Identifies the site name for the host. The value must be an alphanumeric string or blank.
host_cluster_id	Indicates the unique ID for a host cluster.
host_cluster_name	Indicates the unique name for a host cluster.
status_policy	Displays the connectivity requirements that are used to calculate the host status. The value is either complete or redundant. For status_policy redundant: <ul style="list-style-type: none"> • online - The host has redundant connectivity. Enough host ports are logged in to enough nodes such that the removal of a single node or a single host port allows that host to access all of its volumes. In addition, there must be the same total login count from the host to each node within an I/O group. • degraded - Indicates non-redundant connectivity, a state in which a single point of failure prevents a host from accessing at least some of its volumes, or there is no single point of failure but the total login count from the host to each node within an I/O group is not the same. • offline - Unchanged
status_site	Displays the host site connectivity that is used to calculate host status. The result is one of the following values: <ul style="list-style-type: none"> • all - The host status is for connectivity to all nodes where the host has access to volumes. • local - For hosts with a valid site in a dual site topology, the host status is only for connectivity to local host site nodes. Connectivity to nodes in other sites is not included in host status calculation.
owner_id	Displays the ID of the ownership group.
owner_name	Displays the name of the ownership group.

An invocation example

```
lshost
```

The resulting output:

```
id name    port_count iogrp_count status    mapping_count host_cluster_id host_cluster_name protocol
site_id site_name owner_id owner_name
0 hostone 1          4          offline  0              1              varydhost1     scsi
```

```

iogrp_count 4
status offline
site_id
site_name
host_cluster_id
host_cluster_name
protocol nvme
nqn nqn.2014-08.com.example:nvme.host.sys.xyz
node_logged_in_count 0
state offline
nqn nqn.2014-08.org.nvmexpress:uuid:f81d4fae-7dec-11d0-a765-00a0c91e6bf6
node_logged_in_count 0
state offline
status_policy complete
status_site all
owner_id 0
owner_name tenantA

```

[mkhost](#)

Use the **mkhost** command to create a logical host object.

[mkhostcluster](#)

Use the **mkhostcluster** command to create a host cluster object.

[mkvolumehostclustermap](#)

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

rmhost

Use the **rmhost** command to delete a host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

lshostcluster

Use the **lshostcluster** command to generate a list with concise information about all the host clusters that are defined on the system or detailed information about a single host cluster.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

hostcluster_id / hostcluster_name

(Optional) Specifies the ID or name of the host cluster to display information about. If you do not enter a host cluster ID or name, the command displays a list of all host clusters.

Description

This command lists concise information about all the host clusters that are defined on the system or detailed information about a single host cluster.

This table provides the attribute values that can be displayed as output view data.

Table 99. lshostcluster output	
Attribute	Description
id	Indicates the host cluster ID.
name	Indicates host cluster name. The value must be an alphanumeric string of no more than 64 characters.
status	Indicates the status of the host cluster. The values are: <ul style="list-style-type: none">• online indicates that all hosts or members are online.• host_degraded indicates that no hosts are offline but at least one host is degraded.• host_cluster_degraded indicates that one or more hosts are offline and at least one host is online or degraded.• offline indicates that all hosts are offline or there are no hosts or members in the host cluster.
host_count	Indicates the number of hosts that are in the host cluster. The value must be a number in the range 0 - 127.
mapping_count	Indicates the number of shared mappings between the host cluster and any existing volumes. The value must be a number in the range 0 - 2047.
port_count	Indicates the number of host ports that are used for the host cluster mappings to any volumes. The value must be a number in the range 0 - 255.
protocol	Indicates the protocol that the host uses to access the storage. The values are scsi or nvme .
owner_id	Displays the ID of the ownership group.
owner_name	Displays the name of the ownership group.

A concise invocation example

```
lshostcluster
```

The resulting output:

```
id name          status host_count mapping_count port_count protocol owner_id owner_name
0  hostcluster0 online 2           1           4         scsi      0        tenantA
```

A detailed invocation example

```
lshostcluster hostcluster0
```

The detailed resulting output:

```
id:0
name hostcluster0
status online
host_count 6
mapping_count 32
port_count 12
protocol scsi
```

```
owner_id 0
owner_name tenantA
```

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

lshostclustermember

Use the **lshostclustermember** command to generate a list with host information for hosts that belong to the specified host cluster.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data exists to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

hostcluster_id | hostcluster_name

(Required) Specifies the ID or name of the host cluster. If you do not enter a host cluster ID or name, the command displays a list of all recognized host clusters and volume mappings. The value for the ID must be a number and the value for the name must be an alphanumeric string.

Description

This command information about all hosts that belong to the specified host cluster.

This table provides the attribute values that can be displayed as output view data.

Table 100. lshostclustermember output	
Attribute	Description
host_id	Indicates the unique ID of the host.
host_name	Indicates the host name.

Table 100. **lshostclustermember** output (continued)

Attribute	Description
status	Indicates the status of a host for a host cluster. The values are: <ul style="list-style-type: none"> • online indicates that all hosts or members are online. • degraded indicates that no hosts are offline but at least one host is degraded. • offline indicates that all hosts are offline or there are no hosts or members in the host cluster.
type	Indicates the host type. The values are: <ul style="list-style-type: none"> • generic • hpux • tpgs • openmvs • adminlun • hide_secondary
site_id	Indicates the site ID for the host.
site_name	Indicates the site name for the host.

A concise invocation example

```
lshostclustermember
```

The resulting output:

```
host_id host_name status type   site_id site_name
0       host0      online generic 1      site1
1       host1      online generic 2      site2
```

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogr

Use the **rmhostiogr** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

lshostclustervolumemap

Use the **lshostclustervolumemap** command to display a list of volumes that are mapped to all host clusters (or to a specific host cluster).

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

hostcluster_id / hostcluster_name

(Required) Specifies the ID or name for the host cluster that is being mapped to a volume. The command displays a list of all the volumes that are mapped to the specified host cluster and additionally indicates the Small Computer System Interface (SCSI) ID through which they are mapped. If you do not enter a host cluster ID or name, the command displays a list of all recognized host clusters and volume mappings. The value for the ID must be a number and the value for the name must be an alphanumeric string.

Description

This command displays a list of volumes that are mapped to all host clusters or to a specific host cluster.

This table provides the attribute values that can be displayed as output view data.

Table 101. <i>lshostclustervolumemap</i> output	
Attribute	Description
id	Indicates the host cluster ID. The value must be a number in the range 0 - 127.
name	Indicates host cluster name. The value must be an alphanumeric string of no more than 64 characters.
SCSI_id	Indicates the unique ID (volume ID) that is mapped from a host cluster to an I/O group volume. The value must be a number in the range 0 - 2047. This value is blank if the volume is mapped to a host that uses the NVMe protocol.
volume_id	Indicates the unique ID of the volume that is mapped to the host cluster. The value must be a number.
volume_name	Indicates the name for a volume that is mapped to a host cluster. The value must be an alphanumeric string.
volume_UID	Indicates the unique UID of a volume. If the protocol is NVMe, then the volume_UID is set to the NGUID. The value must be an alphanumeric string.
IO_group_id	Indicates the unique ID from the I/O group that the host cluster and volume (from the mapping) are part of. The value must be a number in the range 0 - 3.
IO_group_name	Indicates the I/O group name. The value must be an alphanumeric string.

A concise invocation example

```
lshostclustervolumemap
```

The detailed resulting output:

id	name	SCSI_id	volume_id	volume_name	volume_UID	IO_group_id
IO_group_name						
0	hostcluster0	0	0	vdisk0	60050764009900082000000000000000	0
io_grp0						
0	hostcluster0	1	1	vdisk1	60050764009900082000000000000001	0
io_grp0						
0	hostcluster0	2	2	vdisk2	60050764009900082000000000000002	0
io_grp0						
0	hostcluster0	3	3	vdisk3	60050764009900082000000000000003	0
io_grp0						
1	hostcluster1	0	4	vdisk4	60050764009900082000000000000004	0
io_grp0						
1	hostcluster1	1	5	vdisk5	60050764009900082000000000000005	0
io_grp0						

A concise invocation example

```
lshostclustervolumemap 0
```

The detailed resulting output:

id	name	SCSI_id	volume_id	volume_name	volume_UID	IO_group_id
IO_group_name						
0	hostcluster0	0	0	vdisk0	60050764009900082000000000000000	0
io_grp0						
0	hostcluster0	1	1	vdisk1	60050764009900082000000000000001	0
io_grp0						
0	hostcluster0	2	2	vdisk2	60050764009900082000000000000002	0
io_grp0						
0	hostcluster0	3	3	vdisk3	60050764009900082000000000000003	0
io_grp0						

A concise invocation example

```
lshostclustervolumemap hostcluster1
```

The detailed resulting output:

id	name	SCSI_id	volume_id	volume_name	volume_UID	IO_group_id
IO_group_name						
1	hostcluster1	0	4	vdisk4	60050764009900082000000000000004	0
io_grp0						
1	hostcluster1	1	5	vdisk5	60050764009900082000000000000005	0
io_grp0						

An invocation example of a hostcluster mapped to a single NVMe host

```
lshostclustervolumemap
```

The detailed resulting output:

id	name	SCSI_id	volume_id	volume_name	volume_UID	IO_group_id
IO_group_name	protocol					
0	hostcluster0		12	vdsk0	E0000000000000420050760400BF8299	0
io_grp0	nvme					

Related reference

[addhostclustermember](#)

Use the **addhostclustermember** command to add a host object to a host cluster.

[addhostiogr](#)

Use the **addhostiogr** command to map I/O groups to an existing host object.

[addhostport](#)

Use the **addhostport** command to add worldwide port names (WWPNs), Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) to an existing host object.

chhost

Use the **chhost** command to change the name or type of a host object. This command does not affect any existing host mappings.

chhostcluster

Use the **chhostcluster** to change the name, type, or site of a host cluster object that is part of a host cluster.

lshost

Use the **lshost** command to generate a list with concise information about all the hosts visible to the system and detailed information about a single host.

lshostcluster

Use the **lshostcluster** command to generate a list with concise information about all the host clusters that are defined on the system or detailed information about a single host cluster.

lshostclustermember

Use the **lshostclustermember** command to generate a list with host information for hosts that belong to the specified host cluster.

lshostiogrps

Use the **lshostiogrps** command to display a list the I/O groups that are associated with a specified host.

lshostiplogin

Use the **svcinfo lshostiplogin** command to list the login session type and other details for hosts that are identified by their iSCSI Qualified Name (IQN) and logged in to Ethernet ports that are configured with IP addresses.

lscscsiauth

Use the **lscscsiauth** command to list the Challenge Handshake Authentication Protocol (CHAP) secret that is configured for authenticating an entity to the system.

mkhost

Use the **mkhost** command to create a logical host object.

mkhostcluster

Use the **mkhostcluster** command to create a host cluster object.

mkvolumehostclustermap

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

rmhost

Use the **rmhost** command to delete a host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogrps

Use the **rmhostiogrps** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

lshostiogrp

Use the **lshostiogrp** command to display a list the I/O groups that are associated with a specified host.

Syntax

➔ **lshostiogrp** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

host_id / host_name

(Required) The name or ID of the host for which the list of I/O groups is required.

Description

This command displays a list of all the I/O groups that are mapped to the specified host.

An invocation example

```
lshostiogrp -delim : hostone
```

The resulting output:

```
id:name
0:io_grp0
1:io_grp1
```

[addhostclustermember](#)

Use the **addhostclustermember** command to add a host object to a host cluster.

[addhostiogrp](#)

Use the **addhostiogrp** command to map I/O groups to an existing host object.

[addhostport](#)

Use the **addhostport** command to add worldwide port names (WWPNs), Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) to an existing host object.

[chhost](#)

Use the **chhost** command to change the name or type of a host object. This command does not affect any existing host mappings.

chhostcluster

Use the **chhostcluster** command to change the name, type, or site of a host cluster object that is part of a host cluster.

lshost

Use the **lshost** command to generate a list with concise information about all the hosts visible to the system and detailed information about a single host.

lshostcluster

Use the **lshostcluster** command to generate a list with concise information about all the host clusters that are defined on the system or detailed information about a single host cluster.

lshostclustermember

Use the **lshostclustermember** command to generate a list with host information for hosts that belong to the specified host cluster.

lshostclustervolumemap

Use the **lshostclustervolumemap** command to display a list of volumes that are mapped to all host clusters (or to a specific host cluster).

lshostiplogin

Use the **svcinfo lshostiplogin** command to list the login session type and other details for hosts that are identified by their iSCSI Qualified Name (IQN) and logged in to Ethernet ports that are configured with IP addresses.

lsiscsiauth

Use the **lsiscsiauth** command to list the Challenge Handshake Authentication Protocol (CHAP) secret that is configured for authenticating an entity to the system.

mkhost

Use the **mkhost** command to create a logical host object.

mkhostcluster

Use the **mkhostcluster** command to create a host cluster object.

mkvolumehostclustermap

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

rmhost

Use the **rmhost** command to delete a host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

lshostiplogin

Use the **svcinfo lshostiplogin** command to list the login session type and other details for hosts that are identified by their iSCSI Qualified Name (IQN) and logged in to Ethernet ports that are configured with IP addresses.

Syntax

Parameters

id

(Optional) Object identifier that indicates a configured host IQN, for which login details are to be displayed. This value must be a number in the range 0 - 2047 (Max number of configured iSCSI/iSER IQNs per SVC cluster [512 x 4 = 2048]).

name

(Optional) Object name that indicates a configured host IQN name, for which login details are to be displayed.

-filtervalue attribute=value

(Optional) Specifies a list of one or more filter attributes that matches the specified values; see **-filtervalue?** for the supported attributes.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards when you use the CLI:

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard, which must be the first or last character in the string.
- When you use a wildcard character, you must enclose the filter entry within double quotation marks (""): `lshostiplogin -filtervalue "attribute=value★"`

-filtervalue?

(Optional) Includes all of the valid filter attributes in the report. The following filter attributes are valid for the **lshostiplogin** command:

- login_protocol
- host_id
- host_name

Any parameters specified with the **-filtervalue?** parameter are ignored.

Description

This command lists the login session type and other details.

This table provides the attribute values that can be displayed as output view data.

Table 102. *svcin* **lshostiplogin** output

Attribute	Description
id	Object identifier that indicates a configured host IQN for which login details are displayed.
name	Unique IQN for an iSCSI or iSER host. This IQN must belong to a configured host object.
host_id	Host object ID to which this IQN belongs.
host_name	Host name corresponding to host_id .
login_count	Total number of login sessions that are established by the host to cluster ports to all I/O groups.
login_protocol	Specifies the connection protocol that is used by the configured host to establish sessions with Ethernet ports configured with IP addresses. This value can be one of the following values: <ul style="list-style-type: none"> • iSCSI • iSER • mixed
login	An integer that refers to a single session from the host to any node in the cluster. This value is a number in the range of 0 - 31.
node_id	Node ID of the node to which a login session, referred by login field, is established by host IQN. This value is an integer in the range of 1 - 32.
node_name	Node name of the node to which a login session, referred by login field, is established by host IQN. This value is a string with a maximum of 16 characters.
port_id	Port identifier that indicates the Ethernet port that is displayed by the lspportip view to which login is established. This value is a number in the range of 1 - 12.
host_port_grp_id	Target port group identifier to which port, for login being described, belongs to. This value is a number in the range of 1 - 64.
protocol	Indicates the connection protocol that is used by the configured IP host IQN to establish a login session referred by the login field. This value can be one of the following values: <ul style="list-style-type: none"> • iSCSI • iSER
ip_version	Indicates the IP addressing version. The value that is displayed is either IPv4 or IPv6 .
failover	Identifies whether the session refers to the local or failover IP address. The value that is displayed is either yes or no .

Example 1

```
* IQN "iqn.1996-04.de.suse:01:d4aba8f69a95" logged onto node1 (node_id 1) port 2 and 3 and
node2 (node_id 2) port 2 and 3,
with IPv4 version over iSCSI connection. lshostiplogin displays login sessions as shown below.
```

```

[addhostiogrp](#)

Use the **addhostiogrp** command to map I/O groups to an existing host object.

[addhostport](#)

Use the **addhostport** command to add worldwide port names (WWPNs), Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) to an existing host object.

[chhost](#)

Use the **chhost** command to change the name or type of a host object. This command does not affect any existing host mappings.

[chhostcluster](#)

Use the **chhostcluster** to change the name, type, or site of a host cluster object that is part of a host cluster.

[lshost](#)

Use the **lshost** command to generate a list with concise information about all the hosts visible to the system and detailed information about a single host.

[lshostcluster](#)

Use the **lshostcluster** command to generate a list with concise information about all the host clusters that are defined on the system or detailed information about a single host cluster.

[lshostclustermember](#)

Use the **lshostclustermember** command to generate a list with host information for hosts that belong to the specified host cluster.

[lshostclustervolumemap](#)

Use the **lshostclustervolumemap** command to display a list of volumes that are mapped to all host clusters (or to a specific host cluster).

[lshostiogrp](#)

Use the **lshostiogrp** command to display a list the I/O groups that are associated with a specified host.

[lsiscsiauth](#)

Use the **lsiscsiauth** command to list the Challenge Handshake Authentication Protocol (CHAP) secret that is configured for authenticating an entity to the system.

[mkhost](#)

Use the **mkhost** command to create a logical host object.

[mkhostcluster](#)

Use the **mkhostcluster** command to create a host cluster object.

[mkvolumehostclustermap](#)

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

[rmhost](#)

Use the **rmhost** command to delete a host object.

[rmhostcluster](#)

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

lsiscsiauth

Use the **lsiscsiauth** command to list the Challenge Handshake Authentication Protocol (CHAP) secret that is configured for authenticating an entity to the system.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed. If a capacity is specified, the units must also be included.

Note: Some filters allow the asterisk character (*) when you enter the command. The following rules apply to the use of wildcard characters with the system CLI:

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, you must enclose the filter entry within double quotation marks (" "), as follows:

```
lsiscsiauth -filtervalue "name=md*"
```

-filtervalue?

(Optional) displays a list of filters that can be applied against this view. The following filter attributes are valid for the **lscscauth** command:

- type
- id
- name
- iscsi_auth_method
- iscsi_chap_secret
- cluster_iscsi_auth_method
- cluster_iscsi_chap_secret
- iscsiusername

Description

This command lists the CHAP secret that is configured for authenticating an entity to the system. The command also displays the configured iSCSI authentication method. The `iscsi_auth_method` field can have values of `none` or `chap`.

When you create an iSCSI host by using the **mkhost** command with the **iscsiname** parameter, the host is initially configured with the authentication method as `none`, and no CHAP secret is set. To set a CHAP secret for authenticating the iSCSI host with the system, use the **chhost** command with the **chapsecret** parameter.

This table provides the attribute values that can be displayed as output view data.

Table 103. lscscauth output	
Attribute	Description
type	Indicates the iSCSI system type.
id	Indicates the iSCSI system ID.
name	Indicates the iSCSI system name.
iscsi_auth_method	Indicates the iSCSI authentication method.
iscsi_chap_secret	Indicates whether an iSCSI CHAP secret exists.
cluster_iscsi_auth_method	Indicates clustered system iSCSI authentication method.
cluster_iscsi_chap_secret	Indicates the clustered system iSCSI configured CHAP secret.
iscsiusername	Indicates the iSCSI user name.

An invocation example

```
lscscauth
```

The following output is displayed:

type	id	name	iscsi_auth_method	iscsi_chap_secret	cluster_iscsi_auth_method	cluster_iscsi_chap_secret
host	0	mchost20	none		none	
host	1	mchost30	none		none	
host	2	mchost200	none		none	
host	3	mchost40	none		none	
host	4	mchost240	none		none	
host	5	mchost170	none		none	
host	6	mchost120	none		none	
host	7	mchost60	none		none	
host	8	mchost180	none		none	

host	9	mchost13	none		none
host	10	newhost	none		none

An invocation example

```
lsscsiauth -iscsiusername
```

The following output is displayed:

type	id	name	iscsi_auth_method	iscsiusername	iscsi_chap_secret
host	0	host0	chap	rhel_host1	rhel_secret

An invocation example

```
iscsiusername
```

The following output is displayed:

type	id	name	iscsi_auth_method	iscsiusername	iscsi_chap_secret
host	0	host0	chap	-	rhel_secret

[lshostiplogin](#)

Use the **svcinfo lshostiplogin** command to list the login session type and other details for hosts that are identified by their iSCSI Qualified Name (IQN) and logged in to Ethernet ports that are configured with IP addresses.

[mkhost](#)

Use the **mkhost** command to create a logical host object.

mkhostcluster

Use the **mkhostcluster** command to create a host cluster object.

mkvolumehostclustermap

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

rmhost

Use the **rmhost** command to delete a host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

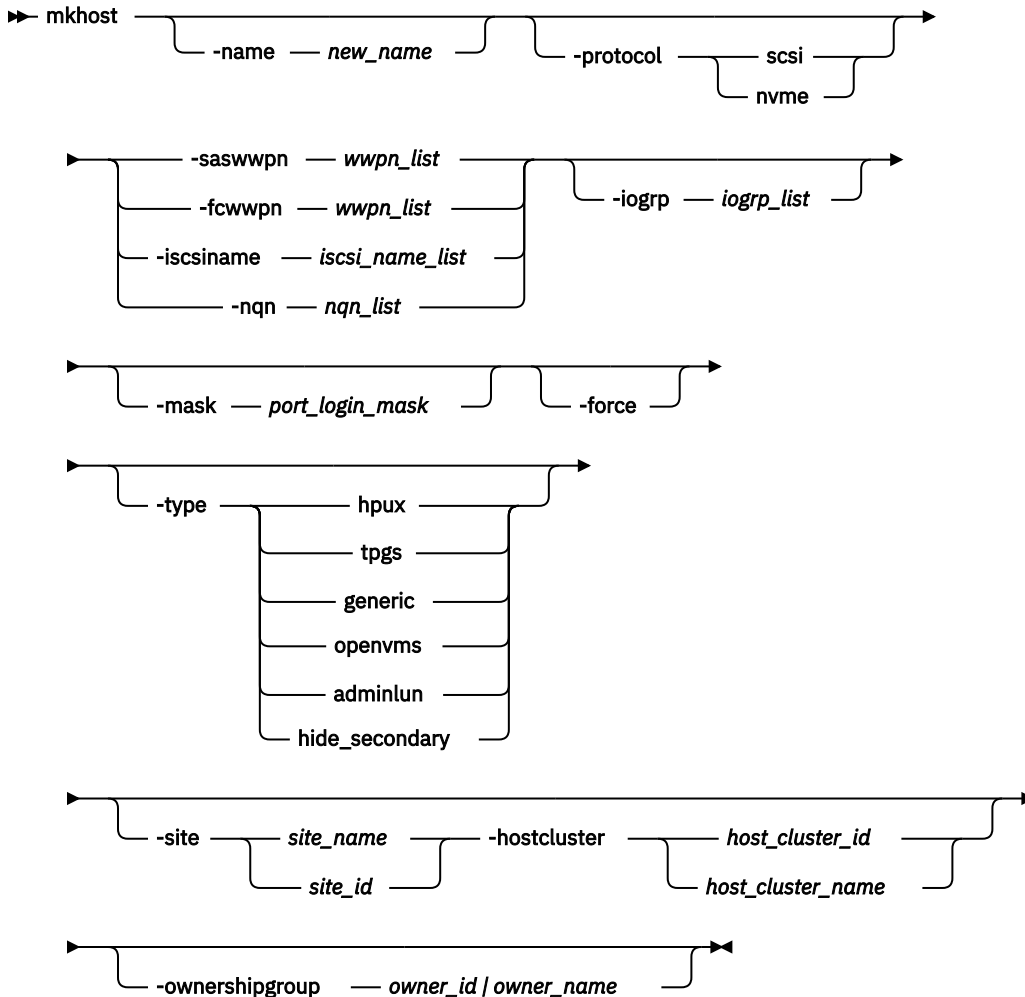

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

mkhost

Use the **mkhost** command to create a logical host object.

Syntax

Parameters

-name new_name

(Optional) Specifies a name or label for the new host object.

-protocol scsi | nvme

(Optional) Specifies the protocol used by the host to communicate with the storage system. The default is **scsi**.

-saswwpn wwpn_list

(Required if you do not use **-iscsiname**, **-fcwwpn**, or **-nqn**.) Specifies a list of Serial Attached SCSI (SAS) WWPNs with a 16-character hexadecimal string.

-fcwwpn wwpn_list

(Required if you do not use **-saswwpn**, **-iscsiname**, or **-nqn**.) Specifies a list of Fibre Channel (FC) WWPNs with a 16-character hexadecimal string.

This command fails if you add the host to an I/O group that is associated with more host ports or host objects than is allowed by the limits within the system.

For additional information, see the **mkvdiskhostmap**, **lssasportcandidate**, and **lsfcportcandidate** commands.

For more information about parameter requirements for your specific host, refer to the following support site: <http://www-03.ibm.com/systems/support/storage/ssic/interoperability.wss>.

An invocation example

```
mkhost -name hostone -saswwpn 210100E08B251DD4:210100F08C262DD8 -force -mask 111111101101
```

The resulting output:

```
Host id [1] successfully created
```

An invocation example

```
mkhost -iscsiname iqn.localhost.hostid.7f000001 -name newhost
```

The resulting output:

```
Host, id [10], successfully created
```

An invocation example

```
mkhost -fcwwpn 210100E08B251EE6:210100F08C262EE7 -type openvms
```

The resulting output:

```
Host, id [1], successfully created
```

An invocation example

```
mkhost -fcwwpn 210100E08B251EE6 -site site1
```

The resulting output:

```
Host, id [1], successfully created
```

An invocation example

```
mkhost -nqn nqn.2014-08.org.nvmexpress:NVMf:uuid:644f51bf-8432-4f59-bb13-5ada20c06397 -protocol nvme
```

The resulting output:

```
Host, id [1], successfully created
```

lshostiplogin

Use the **svcinfo lshostiplogin** command to list the login session type and other details for hosts that are identified by their iSCSI Qualified Name (IQN) and logged in to Ethernet ports that are configured with IP addresses.

lsiscsiauth

Use the **lsiscsiauth** command to list the Challenge Handshake Authentication Protocol (CHAP) secret that is configured for authenticating an entity to the system.

mkhostcluster

Use the **mkhostcluster** command to create a host cluster object.

mkvolumehostclustermap

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

rmhost

Use the **rmhost** command to delete a host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

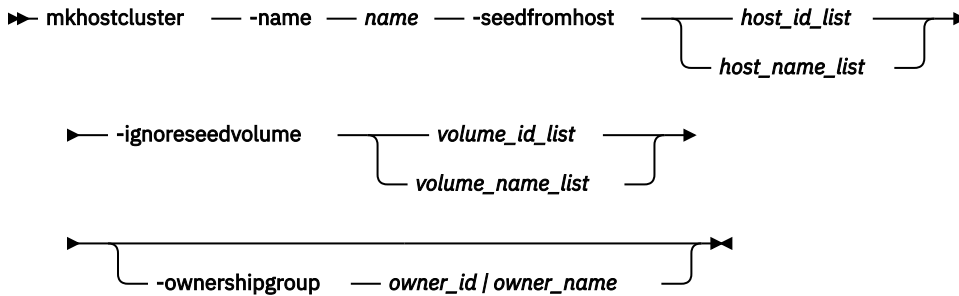

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

mkhostcluster

Use the **mkhostcluster** command to create a host cluster object.

Syntax

Parameters

-name *name*

(Optional) Specifies the name of the host cluster object.

-seedfromhost *host_id_list* / *host_name_list*

(Optional) Adds the specified host to the host cluster. The host cluster mappings to existing volumes then become shared host cluster mappings. If a list of hosts is provided, the hosts are mapped to the same volume that uses the same I/O group and with the same SCSI LUN.

Note: These become shared mappings unless explicitly excluded with **-ignoreseedvolume**.

-ignoreseedvolume *volume_id_list* / *volume_name_list*

(Optional) Specifies volumes that are not part of the shared host cluster mappings. These volumes remain privately mapped to the host or hosts. You must specify **-seedfromhost** if you specify this parameter.

-ownershipgroup *owner_id* / *owner_name*

(Optional) The name or ID of the ownership group to which the object is being added.

Description

This command is used to create a host cluster object. All hosts in a host cluster must use the same protocol (SCSI or NVMe).

Note: This command fails if any of the specified seeding hosts has an associated host throttle.

An invocation example that creates host cluster `myhostcluster` and obtains its mappings from host `myhost1`

```
mkhostcluster -name myhostcluster -seedfromhost myhost1
```

The detailed resulting output:

```
No feedback
```

An invocation example that creates host cluster **myhostcluster** that obtains its mappings from host **myhost1**

The system keeps the mapping to its boot drive (volume_4) private.

```
mkhostcluster -name myhostcluster -seedfromhost myhost1 -ignoreseedvolume volume_4
```

The detailed resulting output:

```
No feedback
```

An invocation example of a list being created

```
mkhostcluster -seedfromhost 1:2:3
```

The detailed resulting output:

```
No feedback
```

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

mkvolumehostclustermap

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

Syntax

Parameters

-scsi scsi_num_arg

(Optional) Specifies the Small Computer System Interface (SCSI) logical unit number (LUN) ID to assign to a volume on the specified host cluster. The SCSI LUN ID is assigned to the volume on the host cluster for all I/O groups that provide access to the volume.

Note: You must use the next available SCSI LUN ID for each host in the host cluster.

The **-scsi** parameter is not supported for NVMe hosts. When a volume is mapped to a host that uses the NVMe protocol, the volume namespace ID (NSID) is assigned by the system. [This parameter is mutually exclusive with -allowmismatchedscsiids.](#)

-allowmismatchedscsiids

(Optional) When you create a new host cluster mapping, this parameter allows the system to allocate non-identical SCSI LUN IDs in the access I/O groups for the volume. This parameter is mutually exclusive with **-scsi**.

-force

(Optional) Forces a new mapping. Specify this parameter to map a volume to a host cluster and that volume is already mapped to at least one host in a different host cluster.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

-hostcluster *hostcluster_id* / *hostcluster_name*

(Required) Specifies the host cluster (by ID or name) to map to the volume. The value for the ID must be a number and the value for the name must be an alphanumeric string.

volume_id* / *volume_name

(Optional) Specifies the volume by ID or name. The value for the ID must be a number and the value for the name must be an alphanumeric string.

Description

This command generates a new mapping between a volume and a host cluster on a system. This volume is then accessible for input or output (I/O) operations to the specified host cluster. The protocol of the host cluster must be compatible with that of the volume.

Note: Due to a limitation in the NVMe specification, HyperSwap volumes and volumes with more than one access I/O group cannot be mapped to NVMe hosts.

If you do not specify a SCSI LUN ID, the system attempts to assign the lowest common SCSI LUN ID in all access I/O groups. The returned ID is the same for all I/O groups to which the volume is mapped. If an identical SCSI LUN ID is not available in all of the access I/O groups, the command fails.

Use the **-allowmismatchedscsiids** parameter to allow the system to allocate non-identical SCSI LUN IDs in the access I/O groups. The lowest value available in each access I/O group is used. It might not be the same in all access I/O groups. Make sure that the host supports this configuration. This parameter cannot be used with the **-scsi** parameter and is not supported for NVMe hosts. If a volume is mapped to a host that uses the NVMe protocol, the volume namespace ID (NSID) is assigned by the system.

An invocation example that maps volume 0 to host cluster 0

```
mkvolumehostclustermap -hostcluster 0 0
```

The detailed resulting output:

```
No feedback
```

An invocation example that maps volume myvolume1 to host cluster myhostcluster and specifies SCSI LUN ID 7

```
mkvolumehostclustermap -hostcluster myhostcluster -scsi 7 myvolume1
```

The detailed resulting output:

```
No feedback
```

rmhost

Use the **rmhost** command to delete a host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

rmhost

Use the **rmhost** command to delete a host object.

Syntax

► **rmhost** 

Parameters

-force

(Optional) Specifies that you want the system to delete the host object even if mappings still exist between this host and volumes. When the **-force** parameter is specified, the mappings are deleted before the host object is deleted.

host_name / host_id

(Required) Specifies the host object to delete, either by ID or by name.

Description

The **rmhost** command deletes the logical host object. The WWPNs that were contained by this host object (if it is still connected and logged in to the fabric) are returned to the unconfigured state. When you issue the **lsfcportcandidate** or **lssasportcandidate** command, the host objects are listed as candidate ports.

Note: This command deletes the associated host throttle if that host is removed.

Remember: This command is unsuccessful if:

- Volume protection is enabled (using the **chsystem** command)
- The host being deleted is mapped to any volume that has received I/O within the defined volume protection time period

If any mappings still exist between this host and volumes, the command fails unless you specify the **-force** parameter. When the **-force** parameter is specified, the **rmhost** command deletes the mappings before the host object is deleted.

An invocation example

```
rmhost host_one
```

The resulting output:

```
No feedback
```

[addhostclustermember](#)

Use the **addhostclustermember** command to add a host object to a host cluster.

[addhostiogrp](#)

Use the **addhostiogrp** command to map I/O groups to an existing host object.

[addhostport](#)

Use the **addhostport** command to add worldwide port names (WWPNs), Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) to an existing host object.

[chhost](#)

Use the **chhost** command to change the name or type of a host object. This command does not affect any existing host mappings.

chhostcluster

Use the **chhostcluster** command to change the name, type, or site of a host cluster object that is part of a host cluster.

lshost

Use the **lshost** command to generate a list with concise information about all the hosts visible to the system and detailed information about a single host.

lshostcluster

Use the **lshostcluster** command to generate a list with concise information about all the host clusters that are defined on the system or detailed information about a single host cluster.

lshostclustermember

Use the **lshostclustermember** command to generate a list with host information for hosts that belong to the specified host cluster.

lshostclustervolumemap

Use the **lshostclustervolumemap** command to display a list of volumes that are mapped to all host clusters (or to a specific host cluster).

lshostiogrp

Use the **lshostiogrp** command to display a list the I/O groups that are associated with a specified host.

lshostiplogin

Use the **svcinfolshostiplogin** command to list the login session type and other details for hosts that are identified by their iSCSI Qualified Name (IQN) and logged in to Ethernet ports that are configured with IP addresses.

lsiscsiauth

Use the **lsiscsiauth** command to list the Challenge Handshake Authentication Protocol (CHAP) secret that is configured for authenticating an entity to the system.

mkhost

Use the **mkhost** command to create a logical host object.

mkhostcluster

Use the **mkhostcluster** command to create a host cluster object.

mkvolumehostclustermap

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

Syntax

Parameters

-removeallhosts

(Optional) Specifies the deletion of all hosts in the host cluster and the associated host cluster object. If any volume mappings exist to the hosts that will be deleted, the command fails unless you specify the **-force** parameter.

-force

(Optional) Specifies that hosts should be deleted even if mappings still exist to volumes. Any mappings are deleted when the hosts are deleted.

If volume protection is enabled and the time period is not expired, the command fails even if the **-force** parameter is used.

-removemappings

(Optional) Specifies that all shared volume mappings in the host cluster are removed when the host cluster is removed. The mappings are deleted before the host cluster is deleted.

-keepmappings

(Optional) Specifies that hosts retain the host cluster shared volume mappings (which become private mappings) when the host cluster is removed.

hostcluster_id / hostcluster_name

(Required) Specifies the host cluster to be removed. The value for the ID must be a number and the value for the name must be an alphanumeric string.

Description

This command removes a host cluster.

Note: This command deletes the associated host cluster throttle if that host cluster is removed.

The **-removeallhosts**, **-keepmappings**, and **-removemappings** parameters are mutually exclusive.

An invocation example that removes host cluster **hostcluster0** and any related hosts

```
rmhostcluster -removeallhosts hostcluster0
```

The detailed resulting output:

```
No feedback
```

An invocation example that removes host cluster **hostcluster0** and all mappings to volumes

```
rmhostcluster -removemappings hostcluster0
```

The detailed resulting output:

```
No feedback
```

An invocation example that removes host cluster `hostcluster0`

The hosts that are removed keep the shared mappings from the host cluster as private mappings.

```
rmhostcluster -keepmappings hostcluster0
```

The detailed resulting output:

```
No feedback
```

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

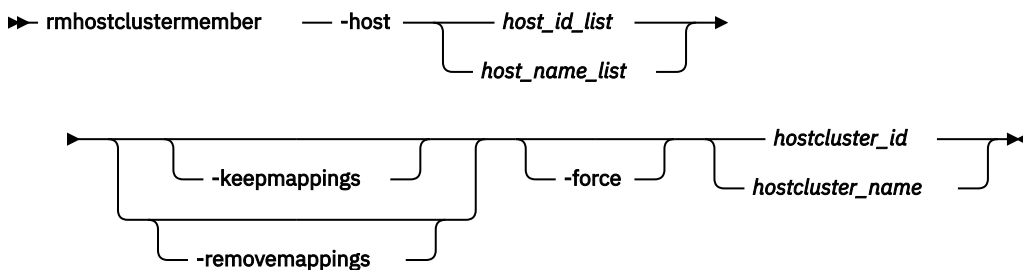

[rmhostport](#)

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

Syntax

Parameters

-host *host_id_list* / *host_name_list*

(Optional) Specifies (by ID or name) the hosts to remove from the host cluster.

-keepmappings

(Optional) Specifies that the host that is removed from the host cluster retains the host cluster's shared volume mappings. The **-keepmappings** and **-removemappings** parameters are mutually exclusive.

-removemappings

(Optional) Specifies that the host that is removed from the host cluster does not retain the host cluster's shared volume mappings. The **-keepmappings** and **-removemappings** parameters are mutually exclusive.

-force

(Optional) Forces a removal. You must specify this parameter when you remove the last host from a host cluster.

hostcluster_id* / *hostcluster_name

(Required) Specifies (by ID or name) that the host cluster that the host is removed from. The value for the ID must be a number and the value for the name must be an alphanumeric string.

Description

This command removes a host from a host cluster object.

An invocation example that removes host 0 from host cluster 0 (and also removes the host mappings)

```
rmhostclustermember -host 0 -removemappings 0
```

The detailed resulting output:

```
No feedback
```

An invocation example that removes host myhost1 from host cluster myhostcluster while keeping the original mappings

```
rmhostclustermember -host myhost1 -keepmappings -force myhostcluster
```

The detailed resulting output:

```
No feedback
```

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

Syntax

Parameters

-hostcluster *hostcluster_id* / *hostcluster_name*

(Required) Specifies the host cluster (by ID or name) to remove from the volume mapping. The value for the ID must be a number and the value for the name must be an alphanumeric string.

-makeprivate *host_id_list* / *host_name_list*

(Optional) Specifies the host or hosts that acquire private mappings from the volume that is being removed from the host cluster. The value for the ID must be a number and the value for the name must be an alphanumeric string.

volume_id / **volume_name**

(Required) Specifies the volume by ID or name. The value for the ID must be a number and the value for the name must be an alphanumeric string.

Description

This command removes an existing host cluster mapping on a host cluster. The volume is then inaccessible for input or output (I/O) transactions from the specified host cluster.

An invocation example that moves a mapping from host cluster 0 to volume 0

```
rmvolumehostclustermap -hostcluster 0 0
```

The resulting output:

```
No feedback
```

A detailed invocation example that removes a mapping from host cluster myhostcluster and adds it to volume myvolume1

```
rmvolumehostclustermap -hostcluster myhostcluster myvolume1
```

The resulting output:

```
No feedback
```

A detailed invocation example that removes a mapping from host cluster myhostcluster and adds it to volume myvolume1

This example allows hosts myhost1 and myhost2 to acquire the private mappings from myvolume1.

```
rmvolumehostclustermap -hostcluster myhostcluster -makeprivate myhost1:myhost2 myvolume1
```

The resulting output:

```
No feedback
```

mkvolumehostclustermap

Use the **mkvolumehostclustermap** command to generate a new mapping between a volume and a host cluster on a clustered system. This volume is then accessible for input or output (I/O) operations to the specified host cluster.

rmhost

Use the **rmhost** command to delete a host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

rmhostiogrp

Use the **rmhostiogrp** command to delete mappings between one or more input/output (I/O) groups and a specified host object.

Syntax

```
➔ rmhostiogrp -iogrp iogrp_list -iogrpall -force host_name host_id ➔
```

Parameters

-iogrp iogrp_list

(Required) Specifies a set of one or more I/O group mappings that will be deleted from the host. You cannot use this parameter with the **iogrpall** parameter.

-iogrpall

(Optional) Specifies that all the I/O group mappings that are associated with the specified host must be deleted from the host. You cannot use this parameter with the **iogrp** parameter.

-force

(Optional) Specifies that you want the system to remove the specified I/O group mappings on the host even if the removal of a host to I/O group mapping results in the loss of host mappings.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

host_id / host_name

(Required) Specifies the identity of the host either by ID or name from which the I/O group mappings must be deleted.

Description

The **rmhostiogrp** command deletes the mappings between the list of I/O groups and the specified host object.

Remember: This command is unsuccessful if:

- Volume protection is enabled (using the **chsystem** command)
- The host I/O group being removed is mapped to any volume that has received I/O within the defined volume protection time period

If a host is defined in two I/O groups, and has access to a volume through both I/O groups, an attempt to remove the host from just one of those I/O groups fails, even with **-force** specified. To resolve this problem, do one of the following:

- Delete the host mappings that are causing the error
- Delete the volumes or the host

Note: When all I/O groups are removed from an Internet Small Computer System Interface (iSCSI) host, and you want to add an iSCSI port to the host, refer to the **addhostport** and **chhost** commands.

An invocation example

```
rmhostiogrp -iogrp 1:2 host0
```

The resulting output:

```
No feedback
```

rmhost

Use the **rmhost** command to delete a host object.

rmhostcluster

Use the **rmhostcluster** command to remove a host cluster.

rmhostclustermember

Use the **rmhostclustermember** command to remove a host from a host cluster object.

rmvolumehostclustermap

Use the **rmvolumehostclustermap** command to remove an existing host cluster mapping to a volume on a clustered system.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

rmhostport

Use the **rmhostport** command to delete worldwide port names (WWPNs) Internet Small Computer System Interface (iSCSI) names, or NVMe Qualified Names (NQN) from an existing host object.

Syntax

Parameters

-saswwpn wwpn_list

(Required if you do not use **-iscsiname**, **-fcwwpn**, or **-nqn**.) Specifies a list of Serial Attached SCSI (SAS) WWPNs with a 16-character hexadecimal string.

-fcwwpn wwpn_list

(Required if you do not use **-iscsiname**, **-saswwpn**, or **-nqn**.) Specifies a list of Fibre Channel (FC) WWPNs with a 16-character hexadecimal string.

-iscsiname iscsi_name_list

(Required if you do not use **-fcwwpn**, **-saswwpn**, or **-nqn**.) Specifies the comma-separated list of iSCSI names. At least one WWPN or iSCSI name must be specified. You cannot use this parameter with the **-fcwwpn** or **-saswwpn** parameter.

-nqn nqn_list

(Required if you do not use **-fcwwpn**, **-saswwpn**, or **-iscsiname**.) Specifies the comma-separated list of NVMe Qualified Names (NQN). The host protocol must be **nvme** to use this parameter.

host_name | host_id

(Required) Specifies the host name or the host ID.

Description

This command deletes the list of host-bus adapter (HBA) WWPNs, iSCSI names, or NQNs from the specified host object. If the WWPN ports are still logged in to the fabric, they become unconfigured and are listed as candidate WWPNs.

Any volumes that are mapped to this host object are automatically unmapped from the ports.

Remember: This command is unsuccessful if:

- Volume protection is enabled (using the **chsystem** command)
- The last host port being deleted is mapped to any volume that has received I/O within the defined volume protection time period

If multiple hosts are mapped to the same active volume, the host port removal is allowed if the host is offline. This allows for the removal of ports from hosts that might be part of the same system.

An invocation example

```
rmhostport -saswwpn 210100E08B251DD4 host1
```

The resulting output:

```
No feedback
```

An invocation example

```
rmhostport -fcwwpn 210100E08B251EE6 host1
```

The resulting output:

```
No feedback
```

An invocation example

```
rmhostport -iscsiname iqn.localhost.hostid.7f000001 mchost13
```

The resulting output:

```
No feedback

Chapter 18. Livedump commands

Use the **livedump** commands to manage the node livedumps on your system.

cancellivedump

Use the **cancellivedump** command to cancel a live dump.

Syntax

➤ **cancellivedump**  *node_name*
node_id

Parameters

node_name/node_id

(Required) Identifies the node name or ID.

Description

Use this command if you issue a **preplivedump** command, but then decide not to issue a **triggerlivedump** command. This releases the resources you allocated for the livedump. This event is recorded in the node trace (.trc) file. For this command to succeed, the node must be in a livedump prepared state.

An invocation example

```
cancellivedump node1
```

The resulting output:

```
No feedback
```

Related reference

[lslivedump](#)

Use the **lslivedump** command to query the live dump state of a node.

[preplivedump](#)

Use the **preplivedump** command to reserve the system resources that are required for livedump.

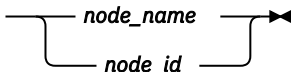

[triggerlivedump](#)

Use the **triggerlivedump** command to capture the metadata that you want to dump, and write the dump file to the internal disk on the node.

lslivedump

Use the **lslivedump** command to query the live dump state of a node.

Syntax

➤ **lslivedump**  *node_name*
node_id

Parameters

node_name/node_id

(Required) Identifies the node name or ID.

Description

You can issue this command repeatedly to determine if a live dump is in progress for the node. This table provides the possible values that are applicable to the attributes that are displayed as data in the output views.

Table 104. lslivedump outputs	
Attribute	Description
inactive	The node has no live dump activity.
prepared	The node is ready to be triggered.
dumping	The node is writing the dump file.

An invocation example

```
lslivedump node1
```

The resulting output:

```
status  
prepared
```

[cancellivedump](#)

Use the **cancellivedump** command to cancel a live dump.

[prelivedump](#)

Use the **prelivedump** command to reserve the system resources that are required for livedump.

[triggerlivedump](#)

Use the **triggerlivedump** command to capture the metadata that you want to dump, and write the dump file to the internal disk on the node.

prelivedump

Use the **prelivedump** command to reserve the system resources that are required for livedump.

Syntax

```
➔ prelivedump 
```

Parameters

node_name/node_id

(Required) Identifies the node name or ID.

Description

You can prepare more than one node for livedump at a time by issuing the **prelivedump** command consecutively. However, you can only trigger one livedump at a time, with an automatic lag time of 30 seconds between each trigger event. This helps maintain node stability.

You can issue multiple **preplivedump** commands on the same node; however, only a **preplivedump** command followed by a **triggerlivedump** command results in output.

Because the livedump resource allocation can take time to execute, you can issue this command to prepare the livedump but trigger it at a later time. This command times out after 60 seconds. The preplivedump event is located in the node trace (.trc) file.

An invocation example

```
preplivedump node1
```

The resulting output:

```
No feedback
```

Use the **cancellivedump** command to cancel a live dump.

[lslivedump](#)

Use the **lslivedump** command to query the live dump state of a node.

[triggerlivedump](#)

Use the **triggerlivedump** command to capture the metadata that you want to dump, and write the dump file to the internal disk on the node.

triggerlivedump

Use the **triggerlivedump** command to capture the metadata that you want to dump, and write the dump file to the internal disk on the node.

Syntax

```
➤ triggerlivedump  node_name
```

Parameters

node_name/node_id

(Required) Identifies the node name or ID.

Description

You can issue this command to trigger a **livedump** command. Only one **triggerlivedump** action can be in progress at one time, with an automatic lag time of 30 seconds between each trigger event. The node must have a live dump state of prepared for this command to succeed. Output is recorded in the node trace (.trc) file.

After you issue the **triggerlivedump** command, the command captures data and returns you to the CLI interface so that you can issue more commands. While you issue more commands, the live dump disk file is written to the disk in the background, and the live dump state shows as dumping. After the write is complete, the state shows as inactive.

An invocation example

```
triggerlivedump node1
```

The resulting output:

```
No feedback
```

lslivedump

Use the **lslivedump** command to query the live dump state of a node.

preplivedump

Use the **preplivedump** command to reserve the system resources that are required for livedump.

Chapter 19. Managed disk commands

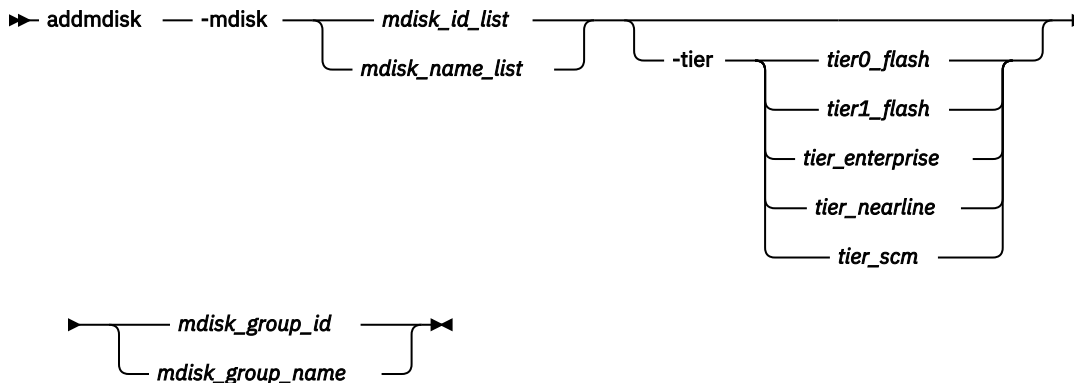

Use the managed disk commands to work with managed disk options on a system.

If the system detects an MDisk, it automatically adds it to the list of known MDisk. If you delete the array that corresponds to the MDisk, the system only deletes the MDisk from the list if the MDisk is offline and it has a mode of unmanaged (it does not belong to a storage pool).

addmdisk

Use the **addmdisk** command to add one or more managed disks to an existing storage pool.

Syntax

Parameters

-mdisk mdisk_id_list / mdisk_name_list

(Required) Specifies one or more managed disk IDs or names to add to the storage pool.

-tier tier0_flash / tier1_flash / tier_enterprise / tier_nearline / tier_scm

(Optional) Specifies the tier of the MDisk or MDisk being added. Unless otherwise specified, the current tier value associated with the MDisk is retained. The values are:

tier0_flash

Specifies a **tier0_flash** hard disk drive or an external MDisk for the newly discovered or external volume.

tier1_flash

Specifies an **tier1_flash** (or flash drive) hard disk drive or an external MDisk for the newly discovered or external volume.

tier_enterprise

Specifies a **tier_enterprise** hard disk drive or an external MDisk for the newly discovered or external volume.

tier_nearline

Specifies a **tier_nearline** hard disk drive or an external MDisk for the newly discovered or external volume.

tier_scm

Specifies a **tier_scm** hard disk drive or an external MDisk for the newly discovered or external volume.

The default value for a newly discovered unmanaged MDisk is *enterprise*. You can change this value by using the **chmdisk** command.

The tier of external managed disks is not detected automatically and is set to *enterprise*. If the external managed disk is made up of flash drives or nearline Serial Attached SCSI (SAS) drives and

you want to use Easy Tier, you must either specify the tier when adding the managed disk to the storage pool or use the **chmdisk** command.

mdisk_group_id | mdisk_group_name

(Required) Specifies the ID or name of the storage pool to add the disks to. When an MDisk is added, the warning threshold for the storage pool is automatically scaled.

Description

This command adds the managed disks that you specify to the storage pool.

If there are no MDisks in the storage pool, the site of the MDisk being added must be well-defined. If there are MDisks in the storage pool, the site information for an MDisk being added to a storage pool with HyperSwap or stretched topology system must match the topology of other MDisks in the storage pool.

Remember: This command cannot be used for child pools.

The disks can be specified in terms of the managed disk ID or the managed disk name. The managed disks must be in unmanaged mode.

Disks that already belong to a storage pool cannot be added to another storage pool until they have been deleted from their current storage pool. You can delete a managed disk from a storage pool under the following circumstances:

- If the managed disk does not contain any extents in use by a volume
- If you can first migrate the extents in use onto other free extents within the storage pool.

Remember: Do not include an Mdisk in a storage pool if it can only be used in image mode.

If the system has I/O groups that are not capable of encryption, you cannot add the MDisk if the MDisk group has an encryption key and the MDisk is not self-encrypting.

An invocation example

```
addmdisk -mdisk mdisk13:mdisk14 -tier tier_nearline Group0
```

The resulting output:

```
No feedback
```

triggermdiskdump (Discontinued)

Attention: The **triggermdiskdump** command is discontinued. Use the **triggerdrivedump** command to collect support data from a disk drive.

chmdisk

Use the **chmdisk** command to modify the name or IBM Easy Tier settings for a managed disk (MDisk).

Syntax

Parameters

-name new_name_arg

(Optional) Specifies the new name to be applied to the managed disk.

-tier tier0_flash / tier1_flash / tier_enterprise / tier_nearline / tier_scm

(Optional) Specifies the new tier of the MDisk. The values are:

tier0_flash

Specifies a tier0_flash hard disk drive or an external MDisk for the newly discovered or external volume.

tier1_flash

Specifies an tier1_flash (or flash drive) hard disk drive or an external MDisk for the newly discovered or external volume.

tier_enterprise

Specifies a tier_enterprise hard disk drive or an external MDisk for the newly discovered or external volume.

tier_nearline

Specifies a tier_nearline hard disk drive or an external MDisk for the newly discovered or external volume.

tier_scm

Specifies a tier_scm hard disk drive or an external MDisk for the newly discovered or external volume.

Note: Since Release 8.1.0, the tier of MDisk mapped from certain types of IBM System Storage® Enterprise Flash is fixed to tier0_flash, and cannot be changed.

-easytierload default / low / medium / high / very_high

(Optional) Specifies the Easy Tier load (amount) to place on a non-array MDisk within its tier.

If Easy Tier is either overusing or under-utilizing a particular MDisk, modify the easy_tier_load value to change the load size.

Note: Specifying *default* returns the performance capability to the value used by the system. Specify *very_high* only if the MDisk tier is *ssd*.

-encrypt yes / no

(Optional) Specifies whether the MDisk is encrypted by using its own encryption resources. The values are yes or no.

Important: If you use SAN Volume Controller in front of an encrypted Storwize V7000 system, you must upgrade Storwize V7000 before you apply encryption to your Storwize V7000 system.

If you apply encryption to your system, you must identify the encrypted MDisk before you apply the encryption. If you specify `chmdisk -encrypt`, the setting is permanent in SAN Volume Controller no matter what Storwize V7000 says.

mdisk_id / mdisk_name

(Required) Specifies the ID or name of the managed disk to modify.

Description

This command modifies the attributes of a managed disk.

Do not use the **-encrypt** parameter if one of the MDisk group's has an encryption key, parent pool, and child pools. Use **chmdisk** for existing self-encrypting MDisk before you start any migration. If an MDisk is self-encrypting, the encrypted property defaults to what is reported.

If you are upgrading your system and the back end of the system uses encrypted storage, you must indicate which MDisk are self-encrypting before you add MDisk to a storage pool. If those MDisk are part of a storage pool, the system assumes that the back-end is not self-encrypting (even if it might be).

If you create encrypted storage pools, the system encrypts locally before it sends data to the back-end. So, the back-end of the system could encrypt again and cannot compress data because the data is random and not compressible.

Note: You must upgrade the system first.

To use encryption on the system that already has encryption that is enabled on the back-end, upgrade the back-end of the system before you enable encryption on the system.

An invocation example

```
chmdisk -tier tier0_flash mdisk13
```

The resulting output:

```
No feedback
```

An invocation example

```
chmdisk -tier tier_nearline mdisk0
```

The resulting output:

```
MDisk Group, id [13], successfully created
```

An invocation example

```
chmdisk -easytierload high mdisk0
```

The resulting output:

```
MDisk Group, id [13], successfully created
```

An invocation example

```
chmdisk -name my_first_mdisk -encrypt yes 0
```

The resulting output:

```
MDisk Group, id [0], successfully changed
```

triggermdiskdump (Discontinued)

Attention: The **triggermdiskdump** command is discontinued. Use the **triggerdrivedump** command to collect support data from a disk drive.

detectmdisk

Use the **detectmdisk** command to manually rescan the Internet Small Computer Systems Interface (iSCSI) or Fibre Channel (FC) network for any new managed disks (MDisks) that might have been added, and to rebalance MDisk access across all available controller device ports.

Syntax

```
➤ detectmdisk — -scope — scope_id ➤
```

Parameters

-scope scope_id

(Optional) Specifies the domain index. The value must be a number from 0 to 6 on non-AWS systems and from 0 to 7 on AWS systems. For example, the value 0 indicates FC and 6 indicates iSCSI.

Description

This command causes the system to rescan the FC or iSCSI network. The rescan discovers any new MDisks that have been added to the system and rebalances MDisk access across the available controller device ports. This command also detects any loss of controller port availability, and updates the SAN Volume Controller configuration to reflect any changes.

Note: Although it might appear that the **detectmdisk** command has completed, some extra time might be required for it to run. The **detectmdisk** is asynchronous and returns a prompt while the command continues to run in the background. You can use the **lsdiscoverystatus** command to show if any discovery operations are running.

In general, the system automatically detects disks when they appear on the network. However, some FC controllers do not send the required SCSI primitives that are necessary to automatically discover the new disks.

If you have attached new storage and the system has not detected it, you might need to run this command before the system detects the new disks.

When back-end controllers are added to the FC SAN and are included in the same switch zone as a system, the system automatically discovers the back-end controller and determines what storage is presented to it. The SCSI LUs that are presented by the back-end controller are displayed as unmanaged MDisks. However, if the configuration of the back-end controller is modified after this has occurred, the system might be unaware of these configuration changes. Run this command to rescan the FC or iSCSI network and update the list of unmanaged MDisks.

Note: The automatic discovery that is performed by the system does not write to an unmanaged MDisk. Only when you add an MDisk to a storage pool, or use an MDisk to create an image mode volume, is the storage actually used.

To identify the available MDisks, issue the **detectmdisk** command to scan the FC or iSCSI network for any MDisks. When the detection is complete, issue the **lsmdiskcandidate** command to show the unmanaged MDisks; these MDisks have not been assigned to a storage pool. Alternatively, you can issue the **lsmdisk** command to view all of the MDisks.

If disk controller ports have been removed as part of a reconfiguration, the SAN Volume Controller detects this change and reports the following error because it cannot distinguish an intentional reconfiguration from a port failure:

```
1630 Number of device logins reduced
```

If the error persists and redundancy has been compromised, the following more serious error is reported:

```
1627 Insufficient redundancy in disk controller connectivity
```

You must issue the **detectmdisk** command to force the SAN Volume Controller to update its configuration and accept the changes to the controller ports.

Note: Only issue the **detectmdisk** command when all of the disk controller ports are working and correctly configured in the controller and the SAN zoning. Failure to do this could result in errors not being reported.

An invocation example

```
detectmdisk
```

The resulting output:

```
No feedback
```

An invocation example

```
detectmdisk -scope 1
```

The resulting output:

```
No feedback
```

dumpallmdiskbadblocks

Use the **dumpallmdiskbadblocks** command to dump bad block counts to a dump file used by the fix procedures and the satask **snap** command.

Syntax

➞ dumpallmdiskbadblocks ➞

Parameters

None

Description

Use the **dumpallmdiskbadblocks** command to dump bad block counts to a readable ASCII dump file for use by fix procedures and the satask **snap** command. The output contains bad blocks for which an error log has been raised.

Use **lsdumps -prefix /dumps/mdisk** to list the output files. Use **cleardumps -prefix /dumps/mdisk** to clear the output files.

The maximum number of dump files is 20.

An invocation example

```
dumpallmdiskbadblocks
```

The resulting output if MDisk 2 and MDisk 5 have bad blocks:

```
Cluster name: my_cluster
Timestamp of dump: Fri Oct 31 11:27:33 2009 UTC

Mdisk id: 2
Mdisk name: mdisk2
Number of bad blocks: 4

Mdisk id: 5
Mdisk name: mdisk 5
Number of bad blocks: 1

Total mdisks with bad blocks: 2
Total number of bad blocks: 5
```

The resulting output if the MDisks have no bad blocks

```
Cluster name: my_cluster
Timestamp of dump: Fri Oct 31 11:27:33 2009 UTC

Total mdisks with bad blocks: 0
Total number of bad blocks: 0
```

dumpmdiskbadblocks

Use the **dumpmdiskbadblocks** command to write the bad block counts and locations that are on a specified MDisk to a dump file for use by fix procedures.

Syntax

➡ **dumpmdiskbadblocks**  **object_id**
object_name

Parameters

object_id | object_name

(Required) Specifies the MDisk for which you need to dump the bad block record table.

Description

Use the **dumpmdiskbadblocks** command to write the bad block counts and locations that are on a specified MDisk to a readable ASCII dump file for use by fix procedures. The output consists of bad blocks for which an event log has been raised.

Use **lsdumps -prefix /dumps/mdisk** to list the output files. Use **cleardumps -prefix /dumps/mdisk** to clear the output files.

The reported event log sequence numbers correspond to the first event seen in the bad block record, which is a 512-block region.

- If there are multiple event logs in the same region, the earliest event sequence is used.
- If there are event logs of different types in the same region, event sequence numbers for bad blocks caused by medium errors on RAID member drives take precedence.
- If a range of bad blocks runs across record boundaries, the sequence number corresponding to the last record is used.

The maximum number of dump files is 20.

An invocation example

```
dumpdiskbadblocks 3
```

The resulting output if the MDisk has bad blocks:

```
Cluster name: my_cluster
Timestamp of dump: Fri Oct 31 11:27:33 2017 UTC

Mdisk id: 3
Mdisk name: mdisk3
Number of bad blocks: 6

Start LBA: 0x1234123412341234
Length: 2
Event log sequence number: 1

Start LBA: 0x5678568102341234
Length: 4
Event log sequence number: 2
```

The resulting output if the MDisk has no bad blocks:

```
Cluster name: my_cluster
Timestamp of dump: Fri Oct 31 11:27:33 2017 UTC

Mdisk id: 3
Mdisk name: mdisk3
Number of bad blocks: 0
```

[lsmdisk](#)

Use the **lsmdisk** command to display a concise list or a detailed view of managed disks (MDisks) visible to the system. It can also list detailed information about a single MDisk.

[lsdiskdumps](#) (Deprecated)

The **lsdiskdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

[lsdisklba](#)

Use the **lsmdisklba** command to list the MDisk and logical block address (LBA) for the specified volume LBA.

lsmdiskcandidate

Use the **lsmdiskcandidate** command to list all unmanaged MDisk by MDisk ID.

lsmdiskextent

Use the **lsmdiskextent** command to display the extent allocation between managed disks and volumes. The output lists a volume ID, volume copy ID, and the number of extents.

lsmdiskmember

Use the **lsmdiskmember** command to display a list of volumes that use extents on the specified MDisk. That is, the volumes use extents on the managed disk that are specified by the MDisk ID.

setquorum (Deprecated)

The **setquorum** command is deprecated. Use the **chquorum** command to change the quorum association.

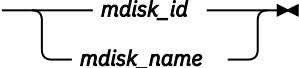

triggermdiskdump (Discontinued)

Attention: The **triggermdiskdump** command is discontinued. Use the **triggerdrivedump** command to collect support data from a disk drive.

includemdisk

Use the **includemdisk** command to include a disk that has been excluded by the system.

Syntax

➤ includemdisk 

Parameters

mdisk_id / mdisk_name

(Required) Specifies the ID or name of the managed disk to add back into the system.

Description

The specified managed disk is included in the system.

You might exclude a disk from the system because of multiple I/O failures. These failures might be caused by noisy (or unstable) links. Once a fabric-related problem has been fixed, the excluded disk can be added back into the system.

Running this command against an MDisk might change its state, whether the state is reported as excluded.

Note: If an MDisk is in the excluded state, is offline, and does not belong to a storage pool, issuing an include command for this MDisk results in the MDisk record being deleted from the system.

An invocation example

```
includemdisk mdisk5
```

The resulting output:

```
No feedback
```

Related reference

addmdisk

Use the **addmdisk** command to add one or more managed disks to an existing storage pool.

applymdisksoftware (Discontinued)

Attention: The **applymdisksoftware** command has been discontinued. Use the **applydrivesoftware** command to update drives.

chmdisk

Use the **chmdisk** command to modify the name or IBM Easy Tier settings for a managed disk (MDisk).

detectmdisk

Use the **detectmdisk** command to manually rescan the Internet Small Computer Systems Interface (iSCSI) or Fibre Channel (FC) network for any new managed disks (MDisks) that might have been added, and to rebalance MDisk access across all available controller device ports.

dumpallmdiskbadblocks

Use the **dumpallmdiskbadblocks** command to dump bad block counts to a dump file used by the fix procedures and the satask **snap** command.

dumpmdiskbadblocks

Use the **dumpmdiskbadblocks** command to write the bad block counts and locations that are on a specified MDisk to a dump file for use by fix procedures.

lslocaldisk

Use the **lslocaldisk** command to display the Amazon Elastic Block Store (Amazon EBS) managed disks (MDisks) visible to the system. This command is available only on cloud systems.

lsmdisk

Use the **lsmdisk** command to display a concise list or a detailed view of managed disks (MDisks) visible to the system. It can also list detailed information about a single MDisk.

lsdiskdumps (Deprecated)

The **lsdiskdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsdisklba

Use the **lsdisklba** command to list the MDisk and logical block address (LBA) for the specified volume LBA.

lsdiskcandidate

Use the **lsdiskcandidate** command to list all unmanaged MDisks by MDisk ID.

lsdiskextent

Use the **lsdiskextent** command to display the extent allocation between managed disks and volumes. The output lists a volume ID, volume copy ID, and the number of extents.

lsdiskmember

Use the **lsdiskmember** command to display a list of volumes that use extents on the specified MDisk. That is, the volumes use extents on the managed disk that are specified by the MDisk ID.

setquorum (Deprecated)

The **setquorum** command is deprecated. Use the **chquorum** command to change the quorum association.

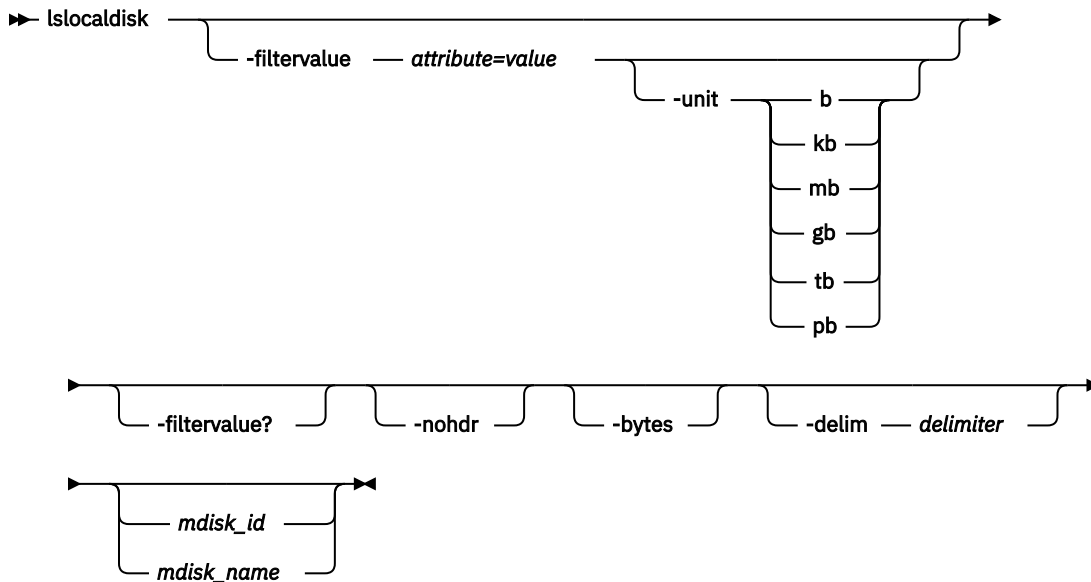

triggermdiskdump (Discontinued)

Attention: The **triggermdiskdump** command is discontinued. Use the **triggerdrivedump** command to collect support data from a disk drive.

lslocaldisk

Use the **lslocaldisk** command to display the Amazon Elastic Block Store (Amazon EBS) managed disks (MDisks) visible to the system. This command is available only on cloud systems.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filter attributes that match the specified values; see **-filtervalue?** for the supported attributes. Only objects with a value that matches the filter attribute value are returned. If **capacity** is specified, the units must also be included. Use the **unit** parameter to interpret the value for size or capacity.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the system CLI:

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard, which must be the first or last character in the string.
- When you use a wildcard character, you must enclose the filter entry within double quotation marks (" "), as follows:

```
lslocaldisk -filtervalue "name=md*"
```

-unit b | kb | mb | gb | tb | pb

(Optional) Specifies the data units for the **-filtervalue** parameter.

Note: **-unit** must be used with **-filtervalue**.

-filtervalue?

(Optional) Includes all of the valid filter attributes in the report. The following filter attributes are valid for the **lslocaldisk** command:

- type
- encrypt
- iops

- node_id

Any parameters that are specified with the **-filtervalue?** parameter are ignored.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-bytes

(Optional) Specifies that you want the report to display all capacities as bytes. Capacity values that are displayed in units other than bytes might be rounded. When you filter on capacity, use a unit of bytes, **-unit b**, for exact filtering.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space that is separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

mdisk_id / mdisk_name

(Optional) Specifies the name or ID of an MDisk. When you use this parameter, the detailed view of the specific MDisk is returned and any value that is specified by the **-filtervalue** parameter is ignored. If you do not specify the **mdisk_id / mdisk_name** parameter, the concise view displays all objects that match the filtering requirements that are specified by the **-filtervalue** parameter.

Description

This command returns a concise list or a detailed view of MDisk visible to the system. This table provides the potential output.

Table 105. <i>lslocaldisk</i> output	
Attribute	Values
mdisk_id	Displays the local MDisk ID.
mdisk_name	Displays the local MDisk name.
status	Displays the local MDisk status (online, offline, or degraded).
mode	Displays the local MDisk mode (ummanaged, managed, or image).
mdisk_grp_id	Displays the ID of the MDisk group that the local disk belongs to.
mdisk_grp_name	Displays the name of the MDisk group that the local disk belongs to.
capacity	Displays the capacity of the disk.
encrypt	Displays the encryption status of the disk. The value is either yes or no.
fabric_type	Displays the type of local MDisk fabric type. This value is the same as lsmdisk fabric_type. The values are: <ul style="list-style-type: none"> • Fibre Channel (fc) • sas • ebs • iscsi
disk_id	Displays the disk ID from the cloud provider (as in AWS), if any.

Table 105. **lslocaldisk** output (continued)

Attribute	Values
type	Displays the local MDisk type. The values are: <ul style="list-style-type: none"> • gp2 • io1 • st1 • sc1 • standard
node_id	Displays the node ID that the local MDisk is attached.
node_name	Displays the node name that the local MDisk is attached.
state	Displays the state of the local MDisk. The values are: <ul style="list-style-type: none"> • available • in-use • attaching • attached • detaching • detached • creating • deleting • deleted • error
iops	Displays the number of I/O operations per second (IOPS) that the local MDisk supports. For Provisioned IOPS SSD volumes, this value represents the number of IOPS that are provisioned for the volume. For General Purpose SSD volumes, this value represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting.
zone	Displays the local MDisk zone.

A concise invocation example

```
lslocaldisk -delim :
```

The resulting output:

```
mdisk_id:mdisk_name:status:mode:mdisk_grp_id:mdisk_grp_name:capacity:encrypt:disk_id:type:node_id:node_name:iops:state:zone
0:mdisk0:online:managed:0:mdiskgrp0:1.0GB:no:vol-09d3adff6553b208e:gp2:1:node1:100:in-use:us-west-2b
```

A detailed invocation example

```
lslocaldisk 0
```

The resulting output:

```
mdisk_id 0
mdisk_name mdisk0
status online
```

```
mode managed
mdisk_grp_id 0
mdisk_grp_name mdiskgrp0
capacity 1.0GB
encrypt no
fabric_type ebs
disk_id vol-09d3adff6553b208e
type gp2
node_id 1
node_name node1
iops 100
state in-use
zone us-west-2b
```

[lsmdiskextent](#)

Use the **lsmdiskextent** command to display the extent allocation between managed disks and volumes. The output lists a volume ID, volume copy ID, and the number of extents.

[lsmdiskmember](#)

Use the **lsmdiskmember** command to display a list of volumes that use extents on the specified MDisk. That is, the volumes use extents on the managed disk that are specified by the MDisk ID.

[setquorum](#) (Deprecated)

The **setquorum** command is deprecated. Use the **chquorum** command to change the quorum association.

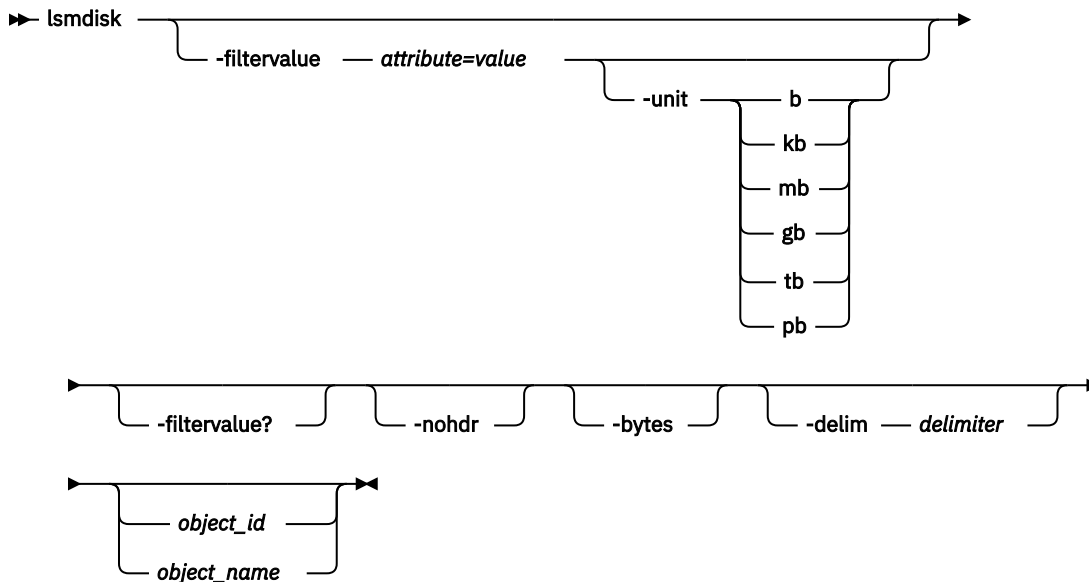

[triggermdiskdump](#) (Discontinued)

Attention: The **triggermdiskdump** command is discontinued. Use the **triggerdrivedump** command to collect support data from a disk drive.

lsmdisk

Use the **lsmdisk** command to display a concise list or a detailed view of managed disks (MDisks) visible to the system. It can also list detailed information about a single MDisk.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filter attributes that match the specified values; see **-filtervalue?** for the supported attributes. Only objects with a value that matches the filter attribute value are returned. If **capacity** is specified, the units must also be included. Use the **unit** parameter to interpret the value for size or capacity.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the system CLI:

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard, which must be the first or last character in the string.
- When you use a wildcard character, you must enclose the filter entry within double quotation marks (" "), as follows:

```
lsmdisk -filtervalue "name=md*"
```

-unit b | kb | mb | gb | tb | pb

(Optional) Specifies the data units for the **-filtervalue** parameter.

Note: **-unit** must be used with **-filtervalue**.

-filtervalue?

(Optional) Includes all of the valid filter attributes in the report. The following filter attributes are valid for the **lsmdisk** command:

- block_size
- capacity
- controller_id

- controller_name
- ctrl_LUN_#
- easy_tier_load
- id
- max_path_count
- mode
- mdisk_grp_id
- mdisk_grp_name
- name
- path_count
- quorum_index
- site_id
- site_name
- status
- tier
- UID

Any parameters that are specified with the **-filtervalue?** parameter are ignored.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-bytes

(Optional) Specifies that you want the report to display all capacities as bytes. Capacity values that are displayed in units other than bytes might be rounded. When you filter on capacity, use a unit of bytes, **-unit b**, for exact filtering.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space that is separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

object_id / object_name

(Optional) Specifies the name or ID of an object. When you use this parameter, the detailed view of the specific object is returned and any value that is specified by the **-filtervalue** parameter is ignored. If you do not specify the **object_id / object_name** parameter, the concise view displays all objects that match the filtering requirements that are specified by the **-filtervalue** parameter.

Description

This command returns a concise list or a detailed view of MDisk visible to the system. This table provides the potential output for MDisk.

Note: Some of the attributes may not be applicable to your system.

Table 106. MDisk output

Attribute	Values
status	<ul style="list-style-type: none"> • online • offline • excluded • degraded_paths • degraded_ports • degraded (This value applies only to internal MDisks.)
mode	unmanaged, managed, image, array
quorum_index	0, 1, 2, or blank if the MDisk is not being used as a quorum disk.
block_size	512, 524 bytes in each block of storage
ctrl_type	4, 6, where 6 is a flash drive that is attached inside a node and 4 is any other device.
tier	<p>The tier this MDisk is assigned to by auto-detection (for internal MDisks) or by the user:</p> <ul style="list-style-type: none"> • tier0_flash • tier1_flash • tier_enterprise • tier_nearline • tier_scm <p>Note: You can change this value by using the chmdisk command.</p>
easy_tier_load	<p>This value controls Easy Tier settings, and is either blank (for arrays) or one of the following values (for MDisks):</p> <ul style="list-style-type: none"> • low • medium • high • very_high
raid_status	<p>offline Array is offline on all nodes.</p> <p>degraded Array has deconfigured or offline members; the array is not fully redundant.</p> <p>syncing Array members are all online. The array is syncing parity or mirrors to achieve redundancy.</p> <p>initting Array members are all online. The array is initializing; the array is fully redundant.</p> <p>online Array members are all online and the array is fully redundant.</p> <p>expanding The array members are all online and the array is expanding.</p>
raid_level	The RAID level of the array (RAID0, RAID1, RAID5, RAID6, RAID10).

Table 106. MDisk output (continued)	
Attribute	Values
redundancy	The number of how many member disks that fail before the array fails.
strip_size	The strip size of the array (in KB).
spare_goal	The number of spares that the array members must be protected by.
spare_protection_min	The minimum number of spares that an array member is protected by.
balanced	Describes if the array is balanced to its spare goals: exact All populated members have exact capability match, exact location match. yes All populated members have at least exact capability match, exact chain, or different enclosure or slot. no Anything else that is not included for yes or exact.
site_id	Indicates the site value for the MDisk. This numeric value is 1, 2, 3, or blank.
site_name	Indicates the site name for the MDisk. This is an alphanumeric value or is blank.
fabric_type	Indicates the type of MDisk. The values are: <ul style="list-style-type: none"> • fc indicates that it is an MDisk from an FC controller. • sas_direct indicates that it is an MDisk from an SAS direct-attached controller. • iscsi indicates that it is an iSCSI controller. • ebs indicates that it is Amazon Elastic Block Store (EBS).
encrypt	Indicates whether the data stored on the MDisk group is encrypted or not encrypted. The values are: <ul style="list-style-type: none"> • yes indicates that the pool has an encryption key. • no indicates that the pool does not have an encryption key but it contains an MDisk or MDiskS that are encrypted. • Blank if the pool doesn't have an encryption key and the pool has no MDiskS.
distributed	Indicates whether the array is distributed. The values are yes or no.
drive_class_id	Indicates the drive class that makes up this array. If -allowsuperior was used during array creation, the lowest used drive class ID is displayed. This value is blank for traditional arrays.
drive_count	Indicates the total width of the array, including rebuild areas. The value is a number in the range 4 - 128. The minimum value for RAID-6 and RAID-10 arrays is 6.
stripe_width	Indicates the width of a single unit of redundancy within a distributed set of drives. The values are: <ul style="list-style-type: none"> • Any number in the range 3 - 16 for RAID-5 arrays. • Any number in the range 4 - 16 for RAID-6 arrays. • An even number in the range 2 - 16 for RAID-10 arrays.

Table 106. MDisk output (continued)

Attribute	Values
rebuild_areas_total	Indicates the total number of rebuild areas set at array creation time. These rebuild areas provide performance but no capacity. The value is a number in the range 1 - 4 for distributed array RAID-5 and RAID-6, and the value is a number in the range 2 - 4 for distributed array RAID-10 (the value is blank for traditional arrays).
rebuild_areas_available	Indicates the number of remaining build areas within the set of arrays. The value is a number in the range 1 - 4 for distributed array RAID-5 and RAID-6, and the value is a number in the range 2 - 4 for distributed array RAID-10 (the value is blank for traditional arrays).
rebuild_areas_goal	Indicates the rebuild areas threshold (minimum limit) at which point the array logs an error. The value is a number in the range 1 - 4 for distributed array RAID-5 and RAID-6, and a number in the range 2 - 4 for distributed array RAID-10 (the value is blank for traditional arrays).
dedupe	Indicates that dedupe is enabled. If dedupe is enabled, duplicate copies of repeating data are compressed or removed.
ctrl_WWNN	Indicates the control worldwide node name (WWNN).
preferred_WWPN	Indicates the preferred worldwide port name (WWPN).
active_WWPN	Indicates the active WWPN.
preferred_iscsi_port_id	Indicates the preferred I/O port identifier, which has the same value as the preferred_WWPN value in the Fibre Channel (FC) domain. The Internet Small Computer System Interface (iSCSI) port ID value is displayed, but the value is blank for non-iSCSI domains. This value must be a numeric value that can range in the range 0 - 1023.
active_iscsi_port_id	Indicates the active I/O port identifier, which has the same value as the active_WWPN value in the FC domain. The Internet Small Computer System Interface (iSCSI) port ID value is displayed, but the value is blank for non-iSCSI domains. This value must be a numeric value that can range in the range 0 - 1023.
over_provisioned	Indicates whether the MDisk is thin-provisioned. The value is no if the MDisk is marked as standard-provisioned . resource-provisioned, the information cannot be verified at the backend. The value is yes or no.
supports_unmap	Indicates whether the mdisk is provided by a controller that indicates that it supports unmapping. The value is no if the MDisk indicates that it does not support unmapping or this information cannot be verified at the backend. The value is yes or no.
provisioning_group_id	Indicates the allocated identifier for the provisioning group affiliated with the MDisk. The identifier lists the MDisk that are contained in the same provisioning group. The value must be an integer (number).
physical_capacity	Indicates the total physical storage capacity of the provisioning group that contains this MDisk. If this MDisk is not over-provisioned the logical capacity is displayed here. The value must be a number (indicated in units) that is rounded to two decimal places.
physical_free_capacity	Indicates the amount of formatted available physical space in the provisioning group that contains this MDisk. If this MDisk is not over-provisioned the remaining logical capacity is displayed instead. The value must be a number (indicated in units) that is rounded to two decimal places.

Table 106. MDisk output (continued)	
Attribute	Values
write_protected	Shows yes if the MDisk is in the write protected state, otherwise no.
effective_used_capacity	The amount of logical data that is written to the MDisk. If this MDisk is not over_provisioned, then this field is blank.
allocated_capacity	The amount of logical capacity that is allocated (by a pool) from this MDisk for volume data and quorum.

Note: The automatic discovery that is performed by the system does not write anything to an unmanaged MDisk. It is only when you add an MDisk to a storage pool, or use an MDisk to create an image mode volume, that the system uses the storage.

To see which MDisks are available, issue the **detectmdisk** command to manually rescan the Fibre Channel or iSCSI network for any new MDisks. Issue the **lsmdiskcandidate** command to show the unmanaged MDisks. These MDisks are not assigned to a storage pool.

Notes:

1. A system connection from a node or node canister port to a storage controller port for a single MDisk is a path. The Mdisk *path_count* value is the number of paths currently being used to submit input/output (I/O) to this MDisk.
2. The MDisk *max_path_count* value is the highest value *path_count* reaches since the MDisk was last fully online.
3. The *preferred_WWPN* is one of the World Wide Port Names (WWPNs) the storage controller specifies as a preferred WWPN. If the controller has nothing that is specified, this is a blank field.
4. The *active_WWPN* indicates the WWPN of the storage controller port currently being used for I/O.
 - a. If no storage controller ports are available for I/O, this is a blank field.
 - b. If multiple controller ports are actively being used for I/O, this field's value is many.

The following define the status fields:

online

The MDisk is online and available.

degraded

(Internal MDisks only) The array has members that are degraded, or the *raid_status* is degraded.

degraded_ports

There are one or more MDisk port errors.

degraded_paths

One or more paths to the MDisk are lost; the MDisk is not online to every node in the system.

offline

All paths to the MDisk are lost.

excluded

The MDisk is excluded from use by the system; the MDisk port error count exceeded the threshold.

A concise invocation example

```
lsmdisk -delim :
```

The concise resulting output:

```
id:name:status:mode:mdisk_grp_id:mdisk_grp_name:capacity:ctrl_LUN_#:controller_name:UID:tier:enc
rypt:site_id:site_name:distributed:dedupe:over_provisioned:supports_unmap
0:mdisk0:online:managed:2:Storwize:200.0GB:0000000000000000:controller0:6005076d0281003d20000000
```

The resulting output:

```
id 0
name mdisk0
status online
mode unmanaged
...
replacement_date
over_provisioned yes
supports_unmap yes
provisioning_group_id 0
physical_capacity 13.10TB
physical_free_capacity 12.22TB
write_protected no
```

A detailed invocation example

```
lsmdisk
```

The resulting output:

id	name	status	mode	mdisk_grp_id	mdisk_grp_name	capacity	ctrl_LUN_#	controller_name	UID
0	mdisk0	online	array	0	mdiskgrp0	826.4GB			
tier		encrypt	site_id	site_name	distributed	dedupe	over_provisioned	supports_unmap	
tier_enterprise	no			yes	no	no		no	

A detailed invocation example

```
lsmdisk -gui
```

The resulting output:

id	name	status	mode	mdisk_grp_id	mdisk_grp_name	capacity	ctrl_LUN_#	controller_name	UID
0	mdisk0	online	array	0	mdiskgrp0	25.5TB			
raid_status	raid_level	redundancy	strip_size	spare_goal	spare_protection_min	balanced			
tier	quorum_index	controller_id	fabric_type	encrypt	site_id	site_name	distributed	dedupe	
over_provisioned	supports_unmap	provisioning_group_id	physical_capacity	physical_free_capacity					
write_protected	allocated_capacity								
initting	raid6	2	256	0	0			exact	
tier0_flash		65535			no			yes	no
no	yes				25.42TB			25.42TB	
no	37.66TB

[addmdisk](#)

Use the **addmdisk** command to add one or more managed disks to an existing storage pool.

[applymdisksoftware](#) (Discontinued)

Attention: The **applymdisksoftware** command has been discontinued. Use the **applydrivesoftware** command to update drives.

[chmdisk](#)

Use the **chmdisk** command to modify the name or IBM Easy Tier settings for a managed disk (MDisk).

[detectmdisk](#)

Use the **detectmdisk** command to manually rescan the Internet Small Computer Systems Interface (iSCSI) or Fibre Channel (FC) network for any new managed disks (MDisks) that might have been added, and to rebalance MDisk access across all available controller device ports.

[dumpallmdiskbadblocks](#)

Use the **dumpallmdiskbadblocks** command to dump bad block counts to a dump file used by the fix procedures and the satask **snap** command.

[dumppmdiskbadblocks](#)

Use the **dumpmdiskbadblocks** command to write the bad block counts and locations that are on a specified MDisk to a dump file for use by fix procedures.

includemdisk

Use the **includemdisk** command to include a disk that has been excluded by the system.

lslocaldisk

Use the **lslocaldisk** command to display the Amazon Elastic Block Store (Amazon EBS) managed disks (MDisks) visible to the system. This command is available only on cloud systems.

lsdiskdumps (Deprecated)

The **lsdiskdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsdisklba

Use the **lsdisklba** command to list the MDisk and logical block address (LBA) for the specified volume LBA.

lsdiskcandidate

Use the **lsdiskcandidate** command to list all unmanaged MDisks by MDisk ID.

lsdiskextent

Use the **lsdiskextent** command to display the extent allocation between managed disks and volumes. The output lists a volume ID, volume copy ID, and the number of extents.

lsdiskmember

Use the **lsdiskmember** command to display a list of volumes that use extents on the specified MDisk. That is, the volumes use extents on the managed disk that are specified by the MDisk ID.

setquorum (Deprecated)

The **setquorum** command is deprecated. Use the **chquorum** command to change the quorum association.

triggermdiskdump (Discontinued)

Attention: The **triggermdiskdump** command is discontinued. Use the **triggerdrivedump** command to collect support data from a disk drive.

lsdiskdumps (Deprecated)

The **lsdiskdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

Related reference

addmdisk

Use the **addmdisk** command to add one or more managed disks to an existing storage pool.

applymdisksoftware (Discontinued)

Attention: The **applymdisksoftware** command has been discontinued. Use the **applydrivesoftware** command to update drives.

chmdisk

Use the **chmdisk** command to modify the name or IBM Easy Tier settings for a managed disk (MDisk).

detectmdisk

Use the **detectmdisk** command to manually rescan the Internet Small Computer Systems Interface (iSCSI) or Fibre Channel (FC) network for any new managed disks (MDisks) that might have been added, and to rebalance MDisk access across all available controller device ports.

dumpallmdiskbadblocks

Use the **dumpallmdiskbadblocks** command to dump bad block counts to a dump file used by the fix procedures and the satask **snap** command.

dumpmdiskbadblocks

Use the **dumpmdiskbadblocks** command to write the bad block counts and locations that are on a specified MDisk to a dump file for use by fix procedures.

includemdisk

Use the **includemdisk** command to include a disk that has been excluded by the system.

lslocaldisk

Use the **lslocaldisk** command to display the Amazon Elastic Block Store (Amazon EBS) managed disks (MDisks) visible to the system. This command is available only on cloud systems.

lsmdisk

Use the **lsmdisk** command to display a concise list or a detailed view of managed disks (MDisks) visible to the system. It can also list detailed information about a single MDisk.

lsmdisklba

Use the **lsmdisklba** command to list the MDisk and logical block address (LBA) for the specified volume LBA.

lsmdiskcandidate

Use the **lsmdiskcandidate** command to list all unmanaged MDisks by MDisk ID.

lsmdiskextent

Use the **lsmdiskextent** command to display the extent allocation between managed disks and volumes. The output lists a volume ID, volume copy ID, and the number of extents.

lsmdiskmember

Use the **lsmdiskmember** command to display a list of volumes that use extents on the specified MDisk. That is, the volumes use extents on the managed disk that are specified by the MDisk ID.

setquorum (Deprecated)

The **setquorum** command is deprecated. Use the **chquorum** command to change the quorum association.

triggermdiskdump (Discontinued)

Attention: The **triggermdiskdump** command is discontinued. Use the **triggerdrivedump** command to collect support data from a disk drive.

lsmdisklba

Use the **lsmdisklba** command to list the MDisk and logical block address (LBA) for the specified volume LBA.

Syntax

Parameters

-vdisklba vdisklba

(Required) Specifies the 64-bit hexadecimal logical block address (LBA) on the volume. The LBA must be specified in hex, with a 0x prefix.

-copy id

(Optional) Specifies the volume copy ID to list the MDisk and LBA for. If this parameter is not specified, the command lists MDisks and LBAs for all volume copies.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space that is separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

vdisk_id / vdisk_name

(Required) Specifies the volume name or ID.

Description

The **lsmdisklba** command returns the logical block address (LBA) of the MDisk that is associated with the volume LBA. For mirrored volume, the command lists the MDisk LBA for both the primary and the copy.

If applicable, the command also lists the range of LBAs on both the volume and MDisk that are mapped in the same extent, or for thin-provisioned disks, in the same grain. If a thin-provisioned volume is offline and the specified LBA is not allocated, the command displays the volume LBA range only.

The `mdisk_lba` field provides the corresponding LBA on the real capacity for the input LBA. For compressed volume copies it is empty, and the system displays only the range of physical LBAs where the compressed input LBA is located.

This table summarizes the data that can be returned with this command.

Table 107. lsmdisklba command output				
Field	standard-provisioned, single copy volume	LBA not allocated on thin-provisioned volume	Mirrored volume with one normal copy and one offline thin-provisioned copy	
			Normal copy	Thin-provisioned copy
copy_id	yes	yes	yes	yes
mdisk_id	yes	no	yes	no
mdisk_name	yes	no	yes	no
type	allocated	unallocated	allocated	offline
mdisk_lba	yes	no	yes	no
mdisk_start	yes	no	yes	no
mdisk_end	yes	no	yes	no
vdisk_start	yes	yes	yes	yes
vdisk_end	yes	yes	yes	yes

An invocation example

```
lsmdisklba -vdisk 0 -vdisklba 0x123
```

The resulting output:

```
copy_id mdisk_id mdisk_name type      mdisk_lba      mdisk_start      mdisk_end      vdisk_start vdisk_end
0         1      mdisk1      allocated 0x0000000000100123 0x0000000000100000 0x00000000001FFFFFF 0x00000000 0x000FFFFF
```

lsmdiskcandidate

Use the **lsmdiskcandidate** command to list all unmanaged MDisks by MDisk ID.

Syntax

➤ **lsmdiskcandidate**  **-nohdr** **-delim** *delimiter*

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This command displays a list of MDisks that are unmanaged. Only the MDisk IDs are displayed.

When back-end controllers are added to the Fibre Channel SAN and are included in the same switch zone as a cluster, the cluster automatically detects the back-end controller to determine which storage is presented to the node. The SCSI logical units that are presented by the back-end controller are displayed as unmanaged MDisks. However, if the configuration of the back-end controller is modified after this occurs, the cluster might be unaware of these configuration changes. You can then request that the cluster rescan the Fibre Channel SAN to update the list of unmanaged MDisks.

Note: The automatic detection that is performed by the cluster does not write anything to an unmanaged MDisk. It is only when you instruct the cluster to add an MDisk to a storage pool or use a MDisk to create an image mode volume that the storage is used.

Check to see which MDisks are available by issuing the **detectmdisk** command to manually scan the Fibre Channel network for any MDisks. Issue the **lsmdiskcandidate** command to show the unmanaged MDisks. These MDisks are not assigned to a storage pool. Alternatively, you can issue the **lsmdisk** command to view all of the MDisks.

An invocation example

```
lsmdiskcandidate
```

The resulting output:

```
id
5
6
7
8
9
10
11
12
13
14
```

lsmdiskextent

Use the **lsmdiskextent** command to display the extent allocation between managed disks and volumes. The output lists a volume ID, volume copy ID, and the number of extents.

Syntax

➤ **lsmdiskextent** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data exists to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

mdisk_name / mdisk_id

(Required) Specifies the specific object ID or name of the specified type.

Description

The command displays a list, in which each entry contains a volume ID, volume copy ID, and the number of extents. These volume copies are using extents on the specified MDisk. The number of extents that are being used on each MDisk is also shown.

Note: You cannot specify this command for MDisks that are in data reduction pools. It means that for:

- Thin-provisioned or compressed volumes, the number extents that are shown is not accurate.
- **standard-provisioned** volumes, the number of extents that are shown is accurate.

A thin-provisioned or compressed volume in a data reduction pool cannot display how many extents are on an MDisk that is in a data reduction pool.

Every volume copy is constructed from one or more MDisks. At times, you might have to determine the relationship between the two objects.

To determine the relationship between volume copies and MDisks, issue the following command for each volume copy:

```
lsvdiskmember vdisk_name / vdisk_id
```

where *vdisk_name / vdisk_id* is the name or ID of the volume copy. It displays a list of IDs that correspond to the MDisks that make up the volume copy.

To determine the relationship between volume copies and MDisks and the number of extents that are provided by each MDisk, you must use the command-line interface. For each volume copy, issue the following command:

```
lsvdiskextent vdisk_name / vdisk_id
```

where *vdisk_name / vdisk_id* is the name or ID of the volume copy. It displays a table of MDisk IDs and the corresponding number of extents that each MDisk is providing as storage for the specified volume copy.

To determine the relationship between MDisks and volume copies, issue the following command for each MDisk:

```
lsmdiskmember mdisk_name / mdisk_id
```

where *mdisk_name / mdisk_id* is the name or ID of the MDisk. It displays a list of IDs that correspond to the volume copies that are using this MDisk.

To determine the relationship between MDisk and volume copies and the number of extents that are used by each volume copy, you must use the command-line interface. For each MDisk, issue the following command:

```
lsmdiskextent mdisk_name / mdisk_id
```

where *mdisk_name* / *mdisk_id* is the name or ID of the MDisk. This command displays a table of volume copy IDs and the corresponding number of extents that are being used by each volume copy. In the output, *number_of_extents* displays either a number (for [standard-provisioned](#) volumes in data reduction pools or volumes in regular pools) or a 1 (for thin-provisioned/compressed volumes in data reduction pools).

An invocation example

```
lsmdiskextent -delim : mdisk0
```

The resulting output:

```
id:number_of_extents:copy_id  
1:1:1
```

triggermdiskdump (Discontinued)

Attention: The **triggermdiskdump** command is discontinued. Use the **triggerdrivedump** command to collect support data from a disk drive.

lsmdiskmember

Use the **lsmdiskmember** command to display a list of volumes that use extents on the specified MDisk. That is, the volumes use extents on the managed disk that are specified by the MDisk ID.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data exists to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

mdisk_id/vdisk_id | mdisk_name/vdisk_name

(Required) Specifies the ID or name of the MDisk or volume copy for which you want a list of volumes that use extents of that MDisk.

Description

This command displays a list of volumes that use extents on the managed disk that are specified by the ID. The list displays members of the respective object and is independent of the state of the individual members. That is, if they are in offline state, they are still displayed.

- A volume in a data reduction storage pool cannot display how many members are on an MDisk that is in a data reduction pool.
- If the MDisk specified is in a data reduction pool, output includes all thin-provisioned and compressed volumes in the pool.
- **standard-provisioned** volume copies in data reduction pools are displayed correctly.

Every volume is constructed from one or more MDisks. To determine the relationship between volume copies and MDisks, issue the following command:

```
lsvdiskmember vdisk_id | vdisk_name
```

where *vdisk_id* / *vdisk_name* is the name or ID of the volume copy. This action displays a list of IDs that correspond to the MDisks that make up the volume copy.

To determine the relationship between volume copies and MDisks and the number of extents that are provided by each MDisk, you must use the command-line interface. For each volume copy, issue the following command:

```
lsvdiskextent vdisk_id | vdisk_name
```

where *vdisk_id* / *vdisk_name* is the name or ID of the volume copy. This command displays a table of MDisk IDs and the corresponding number of extents that each MDisk provides as storage for the volume copy.

To determine the relationship between MDisks and volume copies, issue the following command:

```
lsmdiskmember mdisk_id | mdisk_name
```

where *mdisk_id* / *mdisk_name* is the name or ID of the MDisk. This command displays a list of IDs that correspond to the volume copies that are using this MDisk.

To determine the relationship between MDisks and volume copies and the number of extents that are used by each volume copy, you must use the command-line interface. For each MDisk *mdisk_id* / *mdisk_name*, issue the following command:

```
lsmdiskextent mdisk_id | mdisk_name
```

where *mdisk_id* / *mdisk_name* is the name or ID of the MDisk. This command displays a table of volume copy IDs and the corresponding number of extents that are being used by each volume copy.

An invocation example

```
lsmdiskmember -delim : 1
```

The resulting output:

```
id:copy_id
0:0
1:0
2:0
3:0
4:0
5:0
6:0
```

The **lsmdiskdumps** command is deprecated. Use the **lsdumps** command to display a list of files in a particular dumps directory.

lsmdisklba

Use the **lsmdisklba** command to list the MDisk and logical block address (LBA) for the specified volume LBA.

lsmdiskcandidate

Use the **lsmdiskcandidate** command to list all unmanaged MDisks by MDisk ID.

lsmdiskextent

Use the **lsmdiskextent** command to display the extent allocation between managed disks and volumes. The output lists a volume ID, volume copy ID, and the number of extents.

lsmdiskmember

Use the **lsmdiskmember** command to display a list of volumes that use extents on the specified MDisk. That is, the volumes use extents on the managed disk that are specified by the MDisk ID.

setquorum (Deprecated)

The **setquorum** command is deprecated. Use the **chquorum** command to change the quorum association.

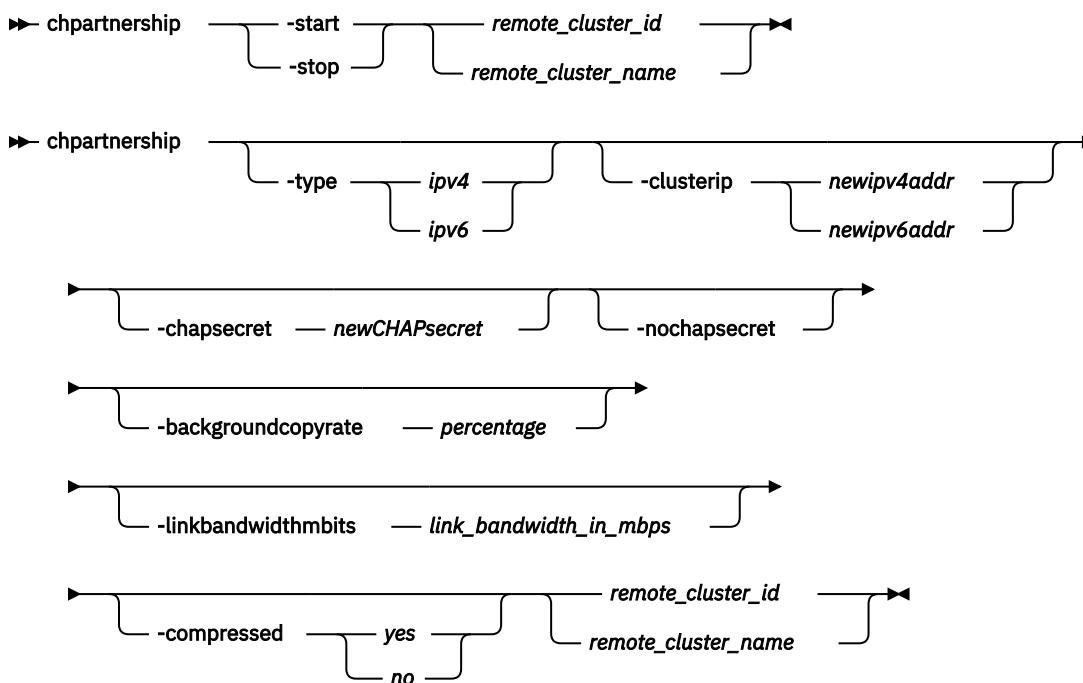

Chapter 20. Copy Service commands

Use the Copy Service commands to work with the Metro Mirror, Global Mirror, and HyperSwap services that are provided by the system.

chpartnership

Use the **chpartnership** command to modify the bandwidth of the partnership between the local system and the remote system that is specified in the command. This affects the bandwidth that is available for background copy in a system partnership by either Metro Mirror or Global Mirror operations. Additionally, use this command to disable and re-enable the partnership, which allows the local system to be disconnected and then reconnected to the remote system.

Syntax

Parameters

-start | -stop

(Optional) Starts or stops a Metro Mirror or Global Mirror partnership. To start or stop a partnership, run the **chpartnership** command from either system.

-type *ipv4* / *ipv6*

(Optional) Specifies the Internet Protocol (IP) address format for the partnership using either of these case-sensitive strings:

- *ipv4* for Internet Protocol Version 4 (IPv4)
- *ipv6* for Internet Protocol Version 6 (IPv6)

This migrates a partnership from *ipv4* to *ipv6* or vice versa.

-clusterip *newipv4addr* / *newipv6addr*

(Optional) Specifies the new partner system IP address, either *ipv4* or *ipv6*. Systems connected over IP links are not displayed by **lspartnershipcandidate** before executing **mkippartnership**. This does not apply to FC-based or FCoE-based connections.

Specify this parameter when creating partnerships with systems connected over native IP links. To change the partner system IP address, first specify **chpartnership -stop** to stop the partnership.

-chapsecret newCHAPsecret

(Optional) Specifies the new Challenge-Handshake Authentication Protocol (CHAP) secret of the partner system. The maximum size of the CHAP secret is eighty alphanumeric characters.

-nochapsecret

(Optional) Resets the CHAP secret used to authenticate with the partner system. Specify **chpartnership -stop** to stop the partnership. Reset the CHAP secret of the partner system when authentication of discovery requests is turned off on the partner system (by specifying **chsystem -rcauthmethod**).

-backgroundcopyrate percentage

(Optional) Specifies the maximum percentage of aggregate link bandwidth that can be used for background copy operations. This parameter can be specified without stopping the partnership. The percentage is a numeric value from 0 to 100, and the default value is 50, which means that a maximum of 50% of the aggregate link bandwidth can be used for background copy operations. This command is mutually-exclusive with all parameters other than **-linkbandwidthmbits**.

Note: If the specified value is non-zero, the combination of both the **-backgroundcopyrate** and the **-linkbandwidthmbits** values must result in a background copy bandwidth of at least 8 megabits per second (Mbps).

-linkbandwidthmbits link_bandwidth_in_mbps

(Optional) Specifies the aggregate bandwidth of the RC link between two clustered systems (systems) in megabits per second (Mbps). It is a numeric value from 1 to 100000, specified in Mbps.

This parameter can be specified without stopping the partnership. This command is mutually-exclusive with all parameters other than **-backgroundcopyrate**.

Note: If the specified value is non-zero, the combination of both the **-backgroundcopyrate** and the **-linkbandwidthmbits** values must result in a background copy bandwidth of at least 8 Mbps.

-compressed yes / no

(Optional) Specifies whether compression is enabled for this partnership. The default value is no.

remote_cluster_ID / remote_cluster_name

(Required) Specifies the remote system ID or name of a partnership. The specified value must match one of the system IDs or names returned after issuing **lspartnershipcandidate**. The specified value must match one of the system IDs or names listed by **lspartnership**.

Remember: Specifying a remote system ID or name with **chpartnership** does not affect the remote system. To change the system name, specify **chsystem**.

To configure the maximum bandwidth available for Metro Mirror intrasystem relationships, specify:

- A local system ID or name
- The **-linkbandwidthmbits** and **-backgroundcopyrate** parameters

Description

This command modifies the bandwidth of the partnership between the local system and the remote system specified in the command. This affects the bandwidth available for a background copy in Metro Mirror or Global Mirror relationships (from the local to the remote system) . To modify the background copy bandwidth from remote system to local system, issue **chpartnership** a second time for the remote system.

Change the CHAP secret or system IP for partnerships created using IP links. Before changing the partner CHAP secret or system IP, stop the partnership.

If a stop partnership is issued, the state is `not_present` briefly before it changes to `fully_configured_stopped`.

Important:

- If you start with a fully configured remote copy partnership, the state (as reported by **lspartnership**) is `fully_configured`.
- If a stop partnership is issued, the state is `not_present` (typically for ten seconds or less) before it becomes `fully_configured_stopped`.

After making the necessary changes, start the partnership.

The system partnership must be in either the `partially_configured_stopped` or `fully_configured_stopped` states to be started.

Note: The local and remote systems in an IP partnership must use the same IP address types, IPv4 or IPv6.

An invocation example

```
chpartnership -stop cluster1
```

The resulting output:

```
No feedback
```

An invocation example to change the allocated background copy rate

```
chpartnership -backgroundcopyrate 20 remote-system-2
```

The resulting output:

```
No feedback
```

An invocation example to change the link bandwidth

```
chpartnership -linkbandwidthmbits 1024 remote-system-2
```

The resulting output:

```
No feedback
```

An invocation example to migrate existing partnership from IPv4 to IPv6 type

```
chpartnership -stop remote-sys-2
chpartnership -type ipv6 -clusterip fe80::200:f8ff:fe21:67cf remote-sys-2
```

The resulting output:

```
No feedback
```

An invocation example to configure a new CHAP secret for a partner

```
chpartnership -stop remote-system-2
chpartnership -chapsecret newpassword remote-system-2
chpartnership -start remote-system-2
```

The resulting output:

```
No feedback
```

An invocation example to configure a new system IP

```
chpartnership -stop remote-system-2  
chpartnership -clusterip 202.49.86.2 -chapsecret newpassword remote-system-2  
chpartnership -start remote-system-2
```

The resulting output:

```
No feedback
```

An invocation example setting the aggregate bandwidth and background copy rate

```
chpartnership -linkbandwidthhmbits 2048 -backgroundcopyrate 100 localCluster
```

The resulting output:

```
No feedback
```

An invocation example enabling compression on an IP replication link

```
chpartnership -compressed yes svtncluster1
```

The resulting output:

```
No feedback
```

[chrconsistgrp](#)

Use the **chrconsistgrp** command to modify attributes of an existing Metro Mirror, Global Mirror, or active-active consistency group, such as changing the name of a consistency group.

[chrrelationship](#)

Use the **chrrelationship** command to modify certain attributes of an existing relationship, such as to add a relationship to a consistency group to remove a relationship from a consistency group, and to change the name of the relationship. You can change one attribute at a time.

[lspartnership](#)

Use the **lspartnership** command to display a concise or detailed view of the current clustered systems (systems) that are associated with the local system.

[lspartnershipcandidate](#)

Use the **lspartnershipcandidate** command to list the clustered systems available for setting up a partnership with the local system. This is a prerequisite for creating inter-system Metro or Global Mirror relationships.

[lsrconsistgrp](#)

Use the **lsrconsistgrp** command to return a concise list or a detailed view of remote copy consistency groups such as Metro Mirror, Global Mirror, or active-active consistency groups visible to the system.

[lsrrelationship](#)

Use the **lsrrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

[lsrrelationshipcandidate](#)

Use the **lsrrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

[lsrrelationshipprogress](#)

Use the **lsrrelationshipprogress** command to display the progress of the background copy of a Metro Mirror, Global Mirror, or active-active relationship as a percentage. When the initial

background copy process for a relationship completes, a null value is displayed for the progress of that relationship.

mkfcpartnership

Use the **mkfcpartnership** command to define partnerships using Fibre Channel (FC) or Fibre Channel over Ethernet (FCoE).

mkippartnership

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

mkpartnership (Discontinued)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrconsistgrp

Use the **mkrconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

mkrrelationship

Specify the **mkrrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrconsistgrp

Use the **rmrconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrrelationship

Use the **rmrrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

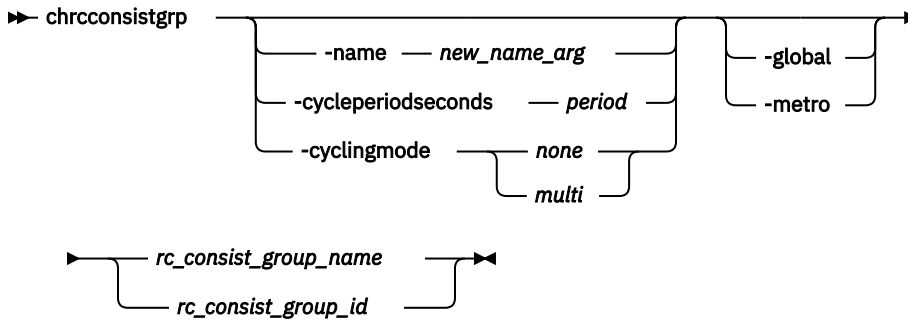

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

chrconsistgrp

Use the **chrconsistgrp** command to modify attributes of an existing Metro Mirror, Global Mirror, or active-active consistency group, such as changing the name of a consistency group.

Syntax

Parameters

-name new_name_arg

(Optional) Specifies the new name to assign to the consistency group.

-cycleperiodseconds period

(Optional) Specifies the cycle period in seconds. The minimum cycle period value is 60 seconds (1 minute) and the maximum is 86400 seconds (1 day). The default is 300 seconds (5 minutes).

This parameter defines an optional cycle period that applies to Global Mirror relationships with a cycling mode of *multi*. A Global Mirror relationship that uses the *multi* cycling_mode performs a complete cycle each period. It might be provided for any relationship, but cannot be used for *none* in Metro or Global Mirror relationships.

-cyclingmode none / multi

(Optional) Specifies the behavior of Global Mirror for this relationship.

- Specifying *none*, the default, gives identical behavior to Global Mirror in previous versions of SAN Volume Controller .
- Specifying *multi* uses the cycling protocol.

To start a relationship with cycling_mode set to *multi*, change volumes must be defined for the relationship.

Note: The cycling_mode can be changed only when the relationship is stopped and in consistent_stopped or inconsistent_stopped states.

-metro

(Optional) Specifies the change in the consistency group's copy type and converts a Global Mirror (with or without change volumes) relationship to a Metro Mirror relationship.

Remember: To use this parameter, the consistency group must be stopped (inconsistent_stopped, consistent_stopped, or idling).

-global

(Optional) Specifies the change in the consistency group's copy type and converts a Metro Mirror relationship to a Global Mirror relationship. This parameter is not mutually exclusive with **-cyclingmode**. If you do not specify **-cyclingmode** and the relationship is Metro Mirror, the cycling_mode value is none.

Remember: To use this parameter, the consistency group must be stopped (inconsistent_stopped, consistent_stopped, or idling).

rc_consist_group_name / rc_consist_group_id

(Required) Specifies the ID or existing name of the consistency group that you want to modify.

Description

This command modifies the specified attributes of the supplied consistency group, one attribute at a time.

All parameters are mutually exclusive except for the **-cyclingmode**, which is mutually exclusive with all parameters but **-global**.

Note: One of the optional parameters must be specified.

You can change a relationship or consistency group between copy types even if replication is stopped. Consistency protection is preserved across all types, so a relationship or consistency group that is in `consistent_copying` state before it is stopped retains the consistent copy on the secondary system when the copying type is changed.

Note: You cannot set cycling mode to `multi-cycling` mode if there is a relationship where the primary and secondary volumes are different sizes.

A Global Mirror consistency group with cycling mode set to *multi* requires that change volumes are defined for the primary and secondary volumes of each relationship in the group before it can be started.

For intersystem relationships, the **-cycleperiodseconds** and **-cyclingmode** parameters can be specified only when the two systems are connected. If the two systems become disconnected while the command is being processed, the command might complete with the change that is performed on the system that received the task invocation only. The other system is updated upon reconnection.

For consistency groups that are active-active, you cannot change the copy type or cycling mode. It means you cannot specify these parameters:

- **-global**
- **-metro**
- **-cyclingmode**

An invocation example to change a consistency group name from `rc_testgrp` to `rc_testone`.

```
chrcconsistgrp -name rc_testone rc_testgrp
```

The resulting output:

```
No feedback
```

Use the **lsrrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

lsrrelationshipcandidate

Use the **lsrrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

lsrrelationshipprogress

Use the **lsrrelationshipprogress** command to display the progress of the background copy of a Metro Mirror, Global Mirror, or active-active relationship as a percentage. When the initial background copy process for a relationship completes, a null value is displayed for the progress of that relationship.

mkfcpartnership

Use the **mkfcpartnership** command to define partnerships using Fibre Channel (FC) or Fibre Channel over Ethernet (FCoE).

mkippartnership

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

mkpartnership (Discontinued)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrconsistgrp

Use the **mkrconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

mkrrelationship

Specify the **mkrrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrconsistgrp

Use the **rmrconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrrelationship

Use the **rmrrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the

relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify `stoprcrelationship -access`.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

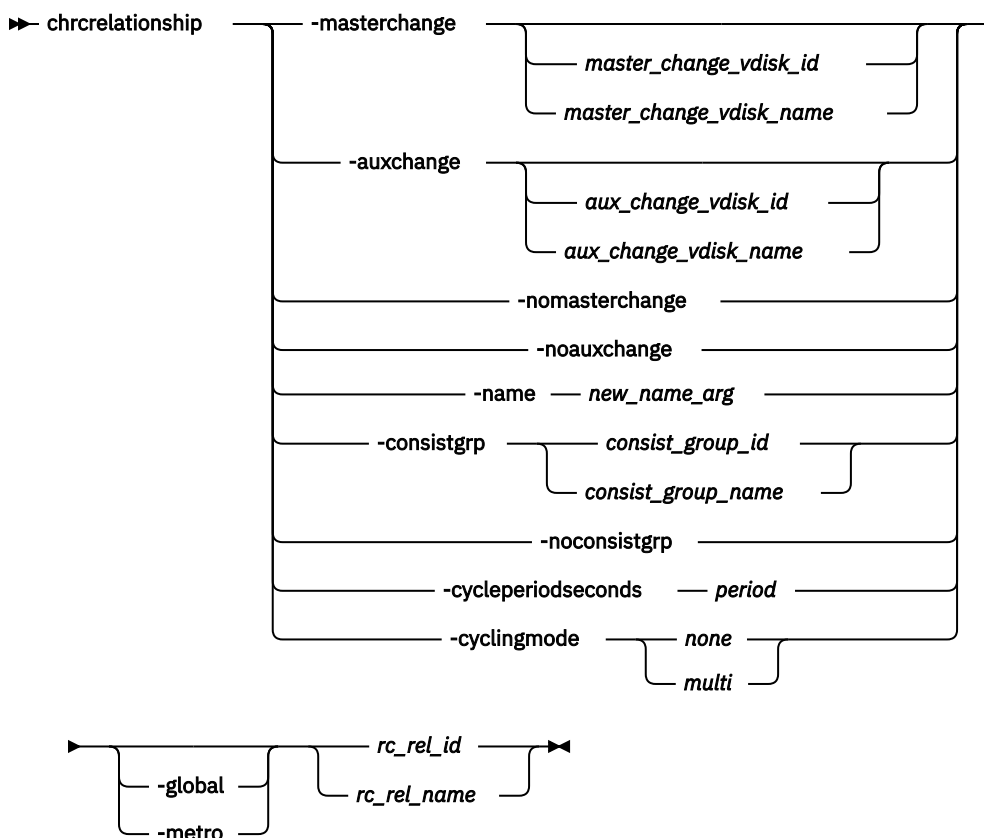

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

chrrelationship

Use the **chrrelationship** command to modify certain attributes of an existing relationship, such as to add a relationship to a consistency group to remove a relationship from a consistency group, and to change the name of the relationship. You can change one attribute at a time.

Syntax

Parameters

-masterchange *master_change_vdisk_id* / *master_change_vdisk_name*

(Optional) Specifies a change volume association for the master volume in the relationship.

-auxchange *aux_change_vdisk_id* / *aux_change_vdisk_name*

(Optional) Specifies a change volume association for the auxiliary volume in the relationship.

-nomasterchange

(Optional) Specifies a defined change volume on the master volume must be removed from the relationship.

Note: To use this parameter the specified change volume must no longer be in use by the relationship, including change volumes of a running relationship (*inconsistent_copying*, *consistent_copying*, or *consistent_synchronized*).

It does not include a primary change volume of a stopped relationship. A secondary change volume of a relationship that is stopped from *consistent_copying* is considered in use if the change volume is supplying the consistent image. If this change volume needs to be removed, the relationships must first be stopped by specifying *stopprrelationship* -access to apply the consistent image to the secondary volume.

-noauxchange

(Optional) Specifies a defined change volume on the auxiliary volume must be removed from the relationship.

Note: To use this parameter the specified change volume must no longer be in use by the relationship, including change volumes of a running relationship (*inconsistent_copying*, *consistent_copying*, or *consistent_synchronized*).

It does not include a primary change volume of a stopped relationship. A secondary change volume of a relationship that is stopped from *consistent_copying* is considered in use if the change volume is supplying the consistent image. If this change volume needs to be removed, the relationships must first be stopped by specifying *stopprrelationship* -access in order to apply the consistent image to the secondary volume.

-name *new_name_arg*

(Optional) Specifies a new label to assign to the relationship.

-consistgrp *consist_group_id* / *consist_group_name*

(Optional) Specifies a new consistency group to assign the relationship to. Only relationships of the same copy type (Global Mirror, Metro Mirror, or active-active) can be assigned to the same consistency group.

-noconsistgrp

(Optional) Removes the specified relationship from a consistency group, making the relationship a stand-alone relationship.

-cycleperiodseconds *period*

(Optional) Specifies the cycle period in seconds. The minimum cycle period value is 60 seconds (1 minute) and the maximum is 86400 seconds (1 day). The default is 300 seconds (5 minutes).

This parameter defines an optional cycle period that applies to Global Mirror relationships with a cycling mode of *multi*. A Global Mirror relationship that uses the *multi* cycling_mode performs a complete cycle at most once each period.

-cyclingmode *none* / *multi*

(Optional) Specifies the behavior of Global Mirror for this relationship.

- Specifying *none*, the default, gives identical behavior to Global Mirror in previous versions of SAN Volume Controller .
- Specifying *multi* uses the cycling protocol.

To start a relationship with *cycling_mode* set to *multi*, change volumes must be defined for the relationship.

Note: The `cycling_mode` can be changed only when the relationship is stopped and in `consistent_stopped` or `inconsistent_stopped` status.

-metro

(Optional) Specifies the change in the relationship's copy type and converts a Global Mirror (with or without change volumes) relationship to a Metro Mirror relationship.

Remember: To use this parameter that the relationship must be stopped (`inconsistent_stopped`, `consistent_stopped`, or `idling`).

-global

(Optional) Specifies the change in the relationship's copy type and converts a Metro Mirror relationship to a Global Mirror relationship. This parameter is not mutually exclusive with **-cyclingmode**. If you do not specify **-cyclingmode** and the relationship is Metro Mirror, the `cycling_mode` value is none.

Remember: To use this parameter that the relationship must be stopped (`inconsistent_stopped`, `consistent_stopped`, or `idling`).

rc_rel_name / rc_rel_id

(Required) Specifies the ID or name of the relationship.

Description

This command modifies the specified attributes of the supplied relationship, one attribute at a time. In addition to changing the name of a consistency group, this command can be used for the following purposes.

Remember:

- All parameters are mutually exclusive except for the **-cyclingmode**, which is mutually exclusive with all parameters but **-global**.
- One of the optional parameters must be specified.

Note: You cannot set cycling mode to multi-cycling mode if the primary and secondary volumes are different sizes.

- You can add a stand-alone relationship to a consistency group by specifying the **-consistgrp** parameter and the name or ID of the consistency group. The relationship and consistency group must be connected when the command is issued and must share the following components:
 - Master system
 - Auxiliary system
 - State (unless the group is empty)
 - Primary (unless the group is empty)
 - Type (unless the group is empty)
 - Cycling mode (unless the group is empty)

When the first relationship is added to an empty group, the group takes on the same state, primary (copy direction), type (Metro Mirror or Global Mirror), and cycling mode as the relationship. Subsequent relationships must have the same state, copy direction, and type as the group in order to be added to it. A relationship can belong to only one consistency group.

- You can remove a relationship from a consistency group by specifying the **-noconsistgrp** parameter and the name or ID of the relationship. Although you do not have to specify or confirm the name of the consistency group, verify which group the relationship belongs to before you issue this command.

This form of the modify relationship command succeeds in the connected or disconnected states. If the systems are disconnected the relationship is only removed from the consistency group on the local system, at the time the command is issued. When the systems are reconnected, the relationship is automatically removed from the consistency group on the other system. Alternatively, you can issue an

explicit modify (**chrcrelationship**) command to remove the relationship from the group on the other system while it is still disconnected.

Note: If you remove all relationships from the group, the relationship type is reset to `empty_group`. When you add a relationship to the empty group, the group again takes on the same type as the relationship.

- To move a relationship between two consistency groups, you must issue the **chrcrelationship** command twice. Use the **-noconsistgrp** parameter to remove the relationship from its current group, and then use the **-consistgrp** parameter with the name of the new consistency group.

You can change a relationship or consistency group between copy types even if replication is stopped. Consistency protection is preserved across all types, so a relationship or consistency group that is in `consistent_copying` state before it is stopped retains the consistent copy on the secondary system when the copying type is changed.

If you add a `consistent_stopped` relationship that uses consistency protection to a `consistent_stopped` consistency group that is not using consistency protection, the system attempts to trigger consistency protection on the consistency group that is not currently using consistency protection. If the relationship or consistency group that is not currently using consistency protection does not have secondary change volumes that are defined, specifying **chrcrelationship -consistgrp** fails. If you add a relationship to a consistency group where at least one is using consistency protection, the resulting consistency group is not mutually consistent, which means that the data on the secondary system for the relationship that is being added is inconsistent with the data on the consistency group. It also means that enabling access to the volume fails.

For intersystem relationships

- The **-name**, **-consistgrp**, **-cycleperiodseconds** and **-cyclingmode** parameters can only be specified when the two systems are connected. If the two systems become disconnected while the command is being processed, the command might be completed with the change performed on the system that received the task invocation only (and the other system is updated upon reconnection). The **-cycleperiodseconds** and **-cyclingmode** parameters can be specified only on stand-alone relationships (not members of a consistency group).
- The **-masterchange** and **-nomasterchange** parameters can only be specified when you run the **chrcrelationship** command on the master system for the relationship, and the **-auxchange** and **-noauxchange** parameters can only be specified when you run the **chrcrelationship** command on the auxiliary system for the relationship.

Remember: You cannot specify a master and auxiliary change volume in the same command.

A change volume must be:

- Used by the relationship that owns it.
- In the same I/O group as the associated master or auxiliary volume.
- The same size as the associated master or auxiliary volume.

A change volume is owned and used by the associated Remote Copy relationship. Therefore, it cannot be:

- Mapped to a host
- Used as source or target of any FlashCopy maps
- Part of any other relationship
- A file system disk

Assigning a change volume to a relationship requires new FlashCopy mappings to be created between the master or auxiliary volume and the associated change volume. Therefore, there must be sufficient deallocated FlashCopy memory in the target I/O group or the command fails.

Note: You cannot use this command if cloud snapshot is enabled on the volume or the volume owner type is `ccloud_backup`.

If the `cycle_period_seconds` for the relationship does not match that of the consistency group it is added to, the newly added relationship copies the `cycle_period_seconds` value from the group. If later removed from the group, the copied `cycle_period_seconds` value remains.

When a Global Mirror relationship with a `cycling_mode` value of *multi* is added to a group that is not empty, both the group and the relationship must be stopped.

For relationships that are active-active, you cannot change the copy type, cycling mode, or the change volumes. It means you cannot specify these parameters:

- **-global**
- **-metro**
- **-cyclingmode**
- **-nomasterchange**
- **-noauxchange**

Remember: For a volume to be configured as a change volume for an active-active relationship, the volume must have the same site name and site ID as the master and auxiliary volume it is being associated with.

An invocation example to change a relationship name from `rccopy1` to `testrel`

```
chcrelationship -name testrel rccopy1
```

The resulting output:

```
No feedback
```

An invocation example to add relationship `rccopy2` to group `newgroup`

```
chcrelationship -consistgrp newgroup rccopy2
```

The resulting output:

```
No feedback
```

An invocation example to remove relationship `rccopy3` from whichever consistency group it is a member of

```
chcrelationship -noconsistgrp rccopy3
```

The resulting output:

```
No feedback
```

An invocation example

```
chcrelationship -cyclingmode multi relB
```

The resulting output:

```
No feedback
```

An invocation example

```
chcrelationship -cycleperiodseconds 60 relC
```

The resulting output:

No feedback

[chpartnership](#)

Use the **chpartnership** command to modify the bandwidth of the partnership between the local system and the remote system that is specified in the command. This affects the bandwidth that is available for background copy in a system partnership by either Metro Mirror or Global Mirror operations. Additionally, use this command to disable and re-enable the partnership, which allows the local system to be disconnected and then reconnected to the remote system.

[chrcconsistgrp](#)

Use the **chrcconsistgrp** command to modify attributes of an existing Metro Mirror, Global Mirror, or active-active consistency group, such as changing the name of a consistency group.

[lspartnership](#)

Use the **lspartnership** command to display a concise or detailed view of the current clustered systems (systems) that are associated with the local system.

[lspartnershipcandidate](#)

Use the **lspartnershipcandidate** command to list the clustered systems available for setting up a partnership with the local system. This is a prerequisite for creating inter-system Metro or Global Mirror relationships.

[lsrcconsistgrp](#)

Use the **lsrcconsistgrp** command to return a concise list or a detailed view of remote copy consistency groups such as Metro Mirror, Global Mirror, or active-active consistency groups visible to the system.

[lsrcrelationship](#)

Use the **lsrcrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

[lsrcrelationshipcandidate](#)

Use the **lsrcrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

[lsrcrelationshipprogress](#)

Use the **lsrcrelationshipprogress** command to display the progress of the background copy of a Metro Mirror, Global Mirror, or active-active relationship as a percentage. When the initial background copy process for a relationship completes, a null value is displayed for the progress of that relationship.

[mkfcpartnership](#)

Use the **mkfcpartnership** command to define partnerships using Fibre Channel (FC) or Fibre Channel over Ethernet (FCoE).

[mkippartnership](#)

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

[mkpartnership \(Discontinued\)](#)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

[mkrrcconsistgrp](#)

Use the **mkrrcconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

[mkrrcrelationship](#)

Specify the **mkrcrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrcconsistgrp

Use the **rmrcconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrcrelationship

Use the **rmrcrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

lspartnership

Use the **lspartnership** command to display a concise or detailed view of the current clustered systems (systems) that are associated with the local system.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed. If a capacity is specified, the units must also be included.

- Some filters allow the asterisk character (*) when you enter the command. The following rules apply to the use of wildcard characters with the SAN Volume Controller command-line interface (CLI):
 - The wildcard character is an asterisk (*).
 - The command can contain a maximum of one wildcard.
 - When you use a wildcard, you must enclose the filter entry within double quotation marks (""):

```
lspartnership -filtervalue "name=md*"
```

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue?

(Optional) displays a list of filters that can be applied against this view. The following filter attributes are valid:

- id
- name

system_id | system_name

(Optional) Specifies the name or ID of a system. Using this parameter displays the detailed view of the specific partner system, and any value that is specified by the **-filtervalue** (which filters a view that is based on specific attribute values that relate to each object type) parameter is ignored. When you specify **system_id** or **system_name** parameter, the concise view of all systems that match the filtering requirements that are specified by the **-filtervalue** parameter are displayed.

Description

This table described attribute values.

Table 108. <i>lspartnership</i> attribute values	
Attribute	Value
id	Indicates the system ID.
name	Indicates the system name.
location	Indicates the system location.
code_level	Indicates the code level.

Table 108. **lspartnership** attribute values (continued)

Attribute	Value
partnership	<p>Indicates the current state of the partnership; not applicable for the local system and is blank.</p> <p>The partnership field can show the following values:</p> <p>fully_configured The mkfcpartnership or mkippartnership command is issued in both directions and the remote system is online and available.</p> <p>partially_configured_local The mkfcpartnership or mkippartnership command is issued from the local system to the remote system. The remote system is online and available for partnership.</p> <p>partially_configured_local_stopped The mkfcpartnership or mkippartnership command is issued from the local system to the remote system. The chpartnership command with the stop parameter is issued from the local system, and the remote system is online and available. Issue chpartnership -start on the local system, and mkfcpartnership or mkippartnership on the remote system</p> <p>not_present The mkfcpartnership or mkippartnership command is issued from the local system to the remote system, and the remote system is not available. The remote system is either offline or not connected to the local system.</p> <p>fully_configured_stopped The mkfcpartnership or mkippartnership command is issued in both directions and the remote system is online and available. The chpartnership command with the stop parameter is issued from the local system.</p> <p>fully_configured_remote_stopped The mkfcpartnership or mkippartnership command is issued in both directions and the remote system is online and available. The chpartnership command with the stop parameter is issued from the remote system.</p> <p>fully_configured_local_excluded The mkfcpartnership or mkippartnership command is issued in both directions. The local system excludes the connection to the remote system and the partnership is unable to sustain the I/O workload for the Metro Mirror or Global Mirror relationships.</p> <p>fully_configured_remote_excluded The mkfcpartnership or mkippartnership command is issued in both directions. The local system excludes the connection to the remote system and the partnership is unable to sustain the I/O workload for the Metro Mirror or Global Mirror relationships.</p> <p>fully_configured_exceeded There are too many systems in the system network and the partnership from the local system to the remote is disabled.</p>
relationship_bandwidth_limit	<p>Indicates the current relationship bandwidth limit setting. The relationship bandwidth limit controls the maximum rate at which any one remote-copy relationship can synchronize. The default value for the relationship bandwidth limit is 25 megabytes per second (MBps).</p>

Table 108. **lspartnership** attribute values (continued)

Attribute	Value
type	Indicates the type of partnership: <ul style="list-style-type: none"> Fibre Channel (FC) Internet Protocol Version 4 (IPv4) or Internet Protocol Version 6 (IPv6) FC partnerships are created connecting two systems over FC or Fibre Channel over Ethernet (FCoE) fabrics. IPv4 or IPv6 partnerships are created connecting two systems over native IP links.
cluster_ip	Indicates the partner system IP address, which can be IPv4 or IPv6. This information is displayed for IP-based partnerships. For IP-based partnership this field displays the system IP address that is specified while the partnership using mkippartnership is created.
chap_secret	Indicates the Challenge-Handshake Access Protocol (CHAP) secret (up to 80 alphanumeric characters) for the partner system. The CHAP authenticates the local system with the partner system during discovery, and Internet Small Computer System Interface (iSCSI) system session creation. For FC-based and FCoE-based relationships this field is always blank.
link_bandwidth_mbits	Indicates the aggregate bandwidth for the Remote Copy (RC) link in megabits per second (Mbps). This is a numeric value from 0 to 100000. If there are multiple links between the local and remote systems, this parameter is set to the sum of the link bandwidths for these links.
background_copy_rate	Indicates the bandwidth allocation for background copy operations that are performed over the replication link. It is expressed as a percentage of the link bandwidth value, and is the maximum rate at which background copy operations are performed. This value is a number from 0 to 100 .
event_log_sequence	Indicates the last sequence number (indicating the last event) from event log for this partnership. This is a numeric value in the range 100 - 8000000. For FC-based and FCoE-based relationships this field is always blank.
max_replication_delay	Indicates the value for maximum replication delay. This value is a number in the range 100 - 360.
compressed	Indicates whether compression is enabled. The values is yes or no (default).

A concise invocation example

```
lspartnership
```

The concise resulting output:

```
id      event_log_sequence  name      location  partnership  type  cluster_ip
000002006BC0A0D4  system-1  local      partially_configured_local  ipv6  fe80::200:f8ff:fe21:67cf
000002006200A0E5  system-2  remote      partially_configured_local  fc
000002006200A0F6  system-3  remote      partially_configured_local  fc
000002006200A0G7  system-4  remote      partially_configured_local  fc
```

A detailed invocation example

```
lspartnership cluster-2
```

The detailed resulting output:

```
id 000002006200A0EA
name system-2
```

```
location remote
partnership partially_configured_local
code_level 6.3.0.0 (build 35.7.1105071000)
console_IP 9.180.28.63:443
gm_link_tolerance 300
gm_inter_system_delay_simulation 0
gm_intra_system_delay_simulation 0
relationship_bandwidth_limit 25
gm_max_host_delay 5
type fc
cluster_ip
chap_secret
event_log_sequence
link_bandwidth_mbits 1024
background_copy_rate 25
max_replication_delay 145
compressed yes
```

Related reference

[chpartnership](#)

Use the **chpartnership** command to modify the bandwidth of the partnership between the local system and the remote system that is specified in the command. This affects the bandwidth that is available for background copy in a system partnership by either Metro Mirror or Global Mirror operations. Additionally, use this command to disable and re-enable the partnership, which allows the local system to be disconnected and then reconnected to the remote system.

[chrconsistgrp](#)

Use the **chrconsistgrp** command to modify attributes of an existing Metro Mirror, Global Mirror, or active-active consistency group, such as changing the name of a consistency group.

[chrrelationship](#)

Use the **chrrelationship** command to modify certain attributes of an existing relationship, such as to add a relationship to a consistency group to remove a relationship from a consistency group, and to change the name of the relationship. You can change one attribute at a time.

[lspartnershipcandidate](#)

Use the **lspartnershipcandidate** command to list the clustered systems available for setting up a partnership with the local system. This is a prerequisite for creating inter-system Metro or Global Mirror relationships.

[lsrconsistgrp](#)

Use the **lsrconsistgrp** command to return a concise list or a detailed view of remote copy consistency groups such as Metro Mirror, Global Mirror, or active-active consistency groups visible to the system.

[lsrrelationship](#)

Use the **lsrrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

[lsrrelationshipcandidate](#)

Use the **lsrrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

[lsrrelationshipprogress](#)

Use the **lsrrelationshipprogress** command to display the progress of the background copy of a Metro Mirror, Global Mirror, or active-active relationship as a percentage. When the initial background copy process for a relationship completes, a null value is displayed for the progress of that relationship.

[mkfcpartnership](#)

Use the **mkfcpartnership** command to define partnerships using Fibre Channel (FC) or Fibre Channel over Ethernet (FCoE).

[mkippartnership](#)

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

mkpartnership (Discontinued)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrcconsistgrp

Use the **mkrcconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

mkrcrelationship

Specify the **mkrcrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrcconsistgrp

Use the **rmrcconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrcrelationship

Use the **rmrcrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

switchrcrelationship

Use the **switchrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

lspartnershipcandidate

Use the **lspartnershipcandidate** command to list the clustered systems available for setting up a partnership with the local system. This is a prerequisite for creating inter-system Metro or Global Mirror relationships.

Syntax

➤ **lspartnershipcandidate** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This command displays a list of systems that are available as candidate partner systems to form a Metro Mirror or Global Mirror partnership between two systems.

Output from the command shows the system ID, name, and configured status of the remote candidate system. The remote candidate system forms a partnership with the local system when you use the **mkippartnership** or **mkfcpartnership** command. The remote system shows the partnership status as **partially_configured_local_stopped** or **partially_configured_local** when you use the **lssystem** command. The **lspartnershipcandidate** command displays the configured status of those remote systems that form a partnership with the local system.

An invocation example

```
lspartnershipcandidate
```

The resulting output:

id	configured	system_name
0000010034E0F430	no	ldsystem26

[chpartnership](#)

Use the **chpartnership** command to modify the bandwidth of the partnership between the local system and the remote system that is specified in the command. This affects the bandwidth that is available for background copy in a system partnership by either Metro Mirror or Global Mirror operations. Additionally, use this command to disable and re-enable the partnership, which allows the local system to be disconnected and then reconnected to the remote system.

chrconsistgrp

Use the **chrconsistgrp** command to modify attributes of an existing Metro Mirror, Global Mirror, or active-active consistency group, such as changing the name of a consistency group.

chrrelationship

Use the **chrrelationship** command to modify certain attributes of an existing relationship, such as to add a relationship to a consistency group to remove a relationship from a consistency group, and to change the name of the relationship. You can change one attribute at a time.

lspartnership

Use the **lspartnership** command to display a concise or detailed view of the current clustered systems (systems) that are associated with the local system.

lsrconsistgrp

Use the **lsrconsistgrp** command to return a concise list or a detailed view of remote copy consistency groups such as Metro Mirror, Global Mirror, or active-active consistency groups visible to the system.

lsrrelationship

Use the **lsrrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

lsrrelationshipcandidate

Use the **lsrrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

lsrrelationshipprogress

Use the **lsrrelationshipprogress** command to display the progress of the background copy of a Metro Mirror, Global Mirror, or active-active relationship as a percentage. When the initial background copy process for a relationship completes, a null value is displayed for the progress of that relationship.

mkfcpartnership

Use the **mkfcpartnership** command to define partnerships using Fibre Channel (FC) or Fibre Channel over Ethernet (FCoE).

mkippartnership

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

mkpartnership (Discontinued)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrconsistgrp

Use the **mkrconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

mkrrelationship

Specify the **mkrrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrconsistgrp

Use the **rmrconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrrelationship

Use the **rmrcrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

lsrcconsistgrp

Use the **lsrcconsistgrp** command to return a concise list or a detailed view of remote copy consistency groups such as Metro Mirror, Global Mirror, or active-active consistency groups visible to the system.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed. If a capacity is specified, the units must also be included.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the SAN Volume Controller command line interface (CLI):

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard, which must be the first or last character in the string.

- When you use a wildcard, you must enclose the filter entry with double quotation marks (" "), as follows:

```
lsrconsistgrp -filtervalue "name=md*"
```

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

object_id / object_name

(Optional) Specifies the name or ID of an object. When you use this parameter, the detailed view of the specific object is displayed and any value that is specified by the **-filtervalue** parameter is ignored. If you do not specify the **object_id / object_name** parameter, the concise view of all objects that match the filtering requirements that are specified by the **-filtervalue** parameter are displayed.

-filtervalue?

(Optional) Specifies that you want your report to display any or all of the list of valid filter attributes. The following filter attributes for the **lsrconsistgrp** command are valid:

- group_id
- name
- master_cluster_id
- master_cluster_name
- aux_cluster_id
- aux_cluster_name
- primary
- state
- relationship_count
- id
- copy_type

Description

This command returns a concise list or a detailed view of remote copy consistency groups such as Global Mirror, Metro Mirror, or active-active consistency groups that are visible to the system.

This table provides possible values for the attributes that are displayed as data in the output views.

Table 109. lsrconsistgrp command output values	
Attribute	Value
primary	Indicates which volumes have the primary role. A primary volume is accessible for write I/O. A secondary volume is not available for write I/O. The direction of copying is from primary to secondary. The values are master, aux, or blank.

Table 109. **lsrconsistgrp** command output values (continued)

Attribute	Value
state	Indicates the state. The values are: <ul style="list-style-type: none"> • consistent_copying • inconsistent_stopped • inconsistent_copying • consistent_stopped • consistent_synchronized • idling • idling_disconnected • inconsistent_disconnected • consistent_disconnected • empty
cycle_period_seconds	Indicates the minimum period in seconds between multiple cycles. The value is a number (integer) in a range in the range 60 - 86400. The default value is 300.
previous_primary	For Global Mirror, Metro Mirror, and GMCV relationships whose state is idling, this field indicates the previous primary volume for the group. For these types of groups, when the state is not idling, the field is blank. For active-active groups that are part of a HyperSwap group, this field is not used and is blank. The valid values are blank, master, or aux.
cycling_mode	Indicates the type of Global Mirror, Metro Mirror, or active-active cycling to use: none (default) or multi
freeze_time	Indicates the time in YYMMDDHHMM format

Table 109. **lsrcconsistgrp** command output values (continued)

Attribute	Value
status	<p>Indicates the relationship status. The values are:</p> <ul style="list-style-type: none"> • online, which indicates that the relationship is online and accessible. If the relationship state is ConsistentSynchronized, ConsistentCopying, or InconsistentCopying the volumes replicate host I/O operations that the primary volume receives. • primary_offline, which indicates that the primary volume in the relationship is offline. This prevents extra I/O operations, and synchronization pauses until the primary volume is online again. • secondary_offline, which indicates that the secondary volume in the relationship is offline. For r Global Mirror relationships in a ConsistentSynchronized state (no change volumes) and Metro Mirror relationships, extra I/O write operations to the primary volume terminate the relationship. • io_channel_offline, which indicates that the remote system is not accessible. For Global Mirror relationships in a ConsistentSynchronized state (no change volumes) and Metro Mirror relationships, extra I/O write operations to the primary volume terminate the relationship. • primary_change_offline, which indicates that the primary change volume in the relationship is offline. For Global Mirror with change volume relationships, the current I/O cycle ends, and a new I/O cycle begins when the primary change volume is online again. • secondary_change_offline, which indicates that the secondary change volume in the relationship is offline. For Global Mirror with change volume relationships, the current I/O cycle pauses and a new I/O cycle resumes when the secondary volume is online again. • change_volumes_needed, indicates an active-active relationship that is in a HyperSwap volume or Global Mirror volume with a change volume relationship. Additionally, at least one change volume is not configured.
sync	<p>Indicates whether a consistent stopped or idling consistency group is still synchronized. The values are in_sync, out_of_sync, or blank.</p> <p>The sync attribute has a value of in_sync when the contents are synchronized (identical) between volumes. If write operations take place on either the primary or secondary volume after a consistent (stopped) or idling state occurs, they will no longer be synchronized.</p>
copy_type	<p>Indicates the copy type. The values are:</p> <ul style="list-style-type: none"> • metro • global • activeactive • blank

Note: The names of the Global Mirror or Metro Mirror relationships and consistency groups might be blank if the relationship or consistency groups are intersystem and the system partnership is disconnected.

A concise invocation example

```
lsrcconsistgrp -delim :
```

The concise resulting output:

```
id:name:master_cluster_id:master_cluster_name:aux_cluster_id:aux_cluster_name:
primary:state:relationship_count:copy_type:cycling_mode:freeze_time

Related reference

[chpartnership](#)

Use the **chpartnership** command to modify the bandwidth of the partnership between the local system and the remote system that is specified in the command. This affects the bandwidth that is available for background copy in a system partnership by either Metro Mirror or Global Mirror operations. Additionally, use this command to disable and re-enable the partnership, which allows the local system to be disconnected and then reconnected to the remote system.

[chrcconsistgrp](#)

Use the **chrcconsistgrp** command to modify attributes of an existing Metro Mirror, Global Mirror, or active-active consistency group, such as changing the name of a consistency group.

[chrcrelationship](#)

Use the **chrcrelationship** command to modify certain attributes of an existing relationship, such as to add a relationship to a consistency group to remove a relationship from a consistency group, and to change the name of the relationship. You can change one attribute at a time.

[lspartnership](#)

Use the **lspartnership** command to display a concise or detailed view of the current clustered systems (systems) that are associated with the local system.

[lspartnershipcandidate](#)

Use the **lspartnershipcandidate** command to list the clustered systems available for setting up a partnership with the local system. This is a prerequisite for creating inter-system Metro or Global Mirror relationships.

lsrrelationship

Use the **lsrrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

lsrrelationshipcandidate

Use the **lsrrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

lsrrelationshipprogress

Use the **lsrrelationshipprogress** command to display the progress of the background copy of a Metro Mirror, Global Mirror, or active-active relationship as a percentage. When the initial background copy process for a relationship completes, a null value is displayed for the progress of that relationship.

mkfcpartnership

Use the **mkfcpartnership** command to define partnerships using Fibre Channel (FC) or Fibre Channel over Ethernet (FCoE).

mkippartnership

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

mkpartnership (Discontinued)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrconsistgrp

Use the **mkrconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

mkrrelationship

Specify the **mkrrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrconsistgrp

Use the **rmrconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrrelationship

Use the **rmrrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

lsrcrelationship

Use the **lsrcrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are returned. If a capacity is specified, the units must also be included.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the SAN Volume Controller CLI:

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard, which must be the first or last character in the string.
- When you use a wildcard, you must enclose the filter entry with double quotation marks (" "), as follows:

```
lsrcrelationship -filtervalue "name=md*"
```

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed even if the **-nohdr** parameter is specified.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The -

delim parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

object_id / object_name

(Optional) Specifies the name or ID of an object. When you use this parameter, the detailed view of the specific object is returned and any value that is specified by the **-filtervalue** parameter is ignored. If you do not specify the *object_id / object_name* parameter, the concise view of all objects that match the filtering requirements that are specified by the **-filtervalue** parameter are displayed.

-filtervalue?

(Optional) Specifies that you want your report to display any or all of the list of valid filter attributes. The valid filter attributes for the **lsrcrelationship** command are:

- RC_rel_id
- RC_rel_name
- master_system_id
- master_system_name
- master_vdisk_id
- master_vdisk_name
- aus_system_id
- aus_system_name
- aus_vdisk_id
- aus_vdisk_name
- primary
- consistency_group_id
- consistency_group_name
- state
- progress
- copy_type

Description

This command returns a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

This table provides possible values for the attributes that are displayed as data in the output views.

Table 110. lsrcrelationship command attributes and values	
Attribute	Value
primary	Indicates which volumes have the primary role. A primary volume is accessible for write I/O. A secondary volume is not available for write I/O. The direction of copying is from primary to secondary. The values are master, aus, or blank.

Table 110. **lsrcrelationship** command attributes and values (continued)

Attribute	Value
state	Indicates the relationship state. The values are: <ul style="list-style-type: none"> • consistent_copying • inconsistent_stopped • inconsistent_copying • consistent_stopped • consistent_synchronized • idling • idling_disconnected • inconsistent_disconnected • consistent_disconnected
progress	Indicates the relationship progress. The value must be a number (integer) in the range 0 - 100.
cycle_period_seconds	Indicates the minimum period in seconds between multiple cycles. The value must be a number (integer) in the range 60 - 86400. The default is 300.
cycling_mode	Indicates the type of Global Mirror, Metro Mirror, or active-active cycling to use. The values are none and multi.
copy_type	Indicates the copy type. The values are <ul style="list-style-type: none"> • metro • global • activeactive • blank
freeze time	Indicates the time in YY/MM/DD/HH/MM format

Table 110. **lsrcrelationship** command attributes and values (continued)

Attribute	Value
status	<p>Indicates the status. The values are:</p> <ul style="list-style-type: none"> • online indicates that the relationship is online and accessible. If the relationship state is ConsistentSynchronized, ConsistentCopying, or InconsistentCopying the volumes replicate host I/O operations that the primary volume receives. • primary_offline indicates that the primary volume in the relationship is offline. This prevents more I/O operations, and synchronization pauses until the primary volume is online again. • secondary_offline indicates that the secondary volume in the relationship is offline. For Global Mirror relationships in a ConsistentSynchronized state (no change volumes) and Metro Mirror relationships, extra I/O write operations to the primary volume terminate the relationship. • io_channel_offline indicates that the remote system is not accessible. For Global Mirror relationships in a ConsistentSynchronized state (no change volumes) and Metro Mirror relationships, extra I/O write operations to the primary volume terminate the relationship. • primary_change_offline indicates that the primary change volume in the relationship is offline. For Global Mirror with change volume relationships, the current I/O cycle ends, and a new I/O cycle begins when the primary change volume is online again. • secondary_change_offline indicates that the secondary change volume in the relationship is offline. For Global Mirror with change volume relationships, the current I/O cycle pauses and a new I/O cycle resumes when the secondary volume is online again. • change_volumes_needed, indicates an active-active relationship that is in a HyperSwap volumes or Global Mirror with change volume relationships. Additionally, at least one change volume is not configured.
sync	<p>Indicates whether a consistent stopped or idling relationship group is still synchronized. The values are in_sync, out_of_sync, or blank.</p> <p>The sync attribute has a value of in_sync when the contents are synchronized (identical) between volumes. If write operations take place on either the primary or secondary volume after a consistent (stopped) or idling state occurs, they will no longer be synchronized.</p>
previous_primary	<p>For Global Mirror, Metro Mirror, and GMCV relationships whose state is idling, this field indicates the previous primary volume for the relationship. For these types of relationships, when the state is not idling, the field is blank. For active-active relationships that are part of a HyperSwap volume, this field is not used and is blank. The valid vales are blank, master, or aux.</p>
master_change_vdisk_name	<p>Indicates the name of the volume that is acting as the master change volume for the relationship (blank if not defined)</p> <p>Note: This field identifies the change volume for the master volume if configured. For an intersystem relationship, if the master volume is in the other system, the master change volume is also in the other system.</p>

Table 110. **lsrcrelationship** command attributes and values (continued)

Attribute	Value
aux_change_vdisk_id	Indicates the ID of the volume that is acting as the auxiliary change volume for the relationship (blank if not defined) Note: This field identifies the change volume for the auxiliary volume, if such a volume is configured. For an intersystem relationship, if the auxiliary volume is in the other system, the auxiliary change volume is also in the other system.
aux_change_vdisk_name	Indicates the name of the volume that is acting as the auxiliary change volume for the relationship (blank if not defined) Note: This field identifies the change volume for the auxiliary volume if configured. For an intersystem relationship, if the auxiliary volume is in the other system, the auxiliary change volume is also in the other system.
bg_copy_priority	Unused.

Note: The names of the Global Mirror, Metro Mirror, or active-active relationships and consistency groups can be blank if the relationship or consistency groups are intersystem and the system partnership is disconnected.

The change_volumes_needed status is set if either the master or auxiliary change volume is not defined for relationships with either of these types:

- Copy type that is set to active-active
- Copy type that is set to global and cycling_mode set to multi

A concise invocation example

```
lsrcrelationship -delim : -filtervalue name=j*
```

rmrcrelationship

Use the **rmrcrelationship** command to delete an existing remote copy relationship.

startrrcconsistgrp

Specify **startrrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrrcrelationship

Use the **startrrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprrcrelationship -access**.

stoprrcconsistgrp

Use the **stoprrcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprrcrelationship

Use the **stoprrcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrrcconsistgrp

Use the **switchrrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

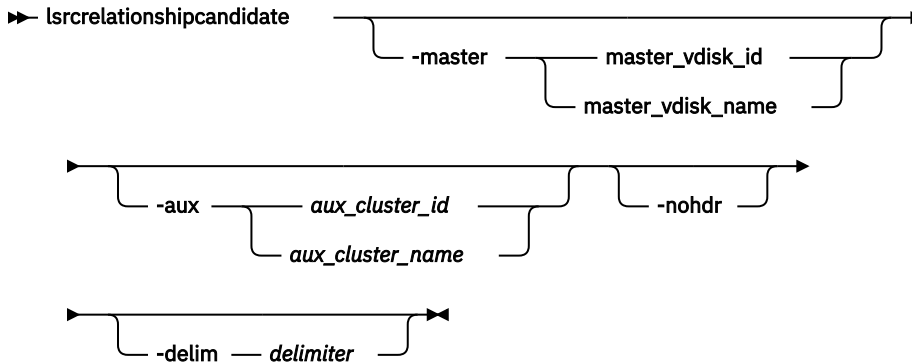

switchrrcrelationship

Use the **switchrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

lsrelationshipcandidate

Use the **lsrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

Syntax

Parameters

-master master_vdisk_id / master_vdisk_name

(Required) Specifies a particular volume to use as the master volume. The command finds candidates that match the size of this volume. If you are requesting candidate volumes on the local system, this command also matches the io_group.

-aux aux_cluster_id / aux_cluster_name

(Required) Specifies a remote system with volume candidates for an intersystem relationship. If you do not specify this parameter, the candidates on the local system are displayed.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This command displays a list of volumes that can be either the master or the auxiliary disk for a Metro Mirror, Global Mirror, or active-active relationship. Volume IDs and names are displayed.

Note: Volumes that are flash disks are excluded from the view when a FlashCopy map is constructed.

An invocation example

```
lsrelationshipcandidate -delim :
```

The resulting output:

```
id:vdisk_name
0:vdisk0
4:vdisk4
```

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

rcrelationship_id / rcrelationship_name

(Required) Specifies the object ID or name of the specified type.

Description

This command displays the progress of the background copy of a Metro Mirror, Global Mirror, or active-active relationship as a percentage.

An invocation example

```
lsrcrelationshipprogress -delim : 0
```

The resulting output:

```
id:progress
0:58
```

[chpartnership](#)

Use the **chpartnership** command to modify the bandwidth of the partnership between the local system and the remote system that is specified in the command. This affects the bandwidth that is available for background copy in a system partnership by either Metro Mirror or Global Mirror operations. Additionally, use this command to disable and re-enable the partnership, which allows the local system to be disconnected and then reconnected to the remote system.

[chrconsistgrp](#)

Use the **chrconsistgrp** command to modify attributes of an existing Metro Mirror, Global Mirror, or active-active consistency group, such as changing the name of a consistency group.

[chrrelationship](#)

Use the **chrrelationship** command to modify certain attributes of an existing relationship, such as to add a relationship to a consistency group to remove a relationship from a consistency group, and to change the name of the relationship. You can change one attribute at a time.

[lspartnership](#)

Use the **lspartnership** command to display a concise or detailed view of the current clustered systems (systems) that are associated with the local system.

[lspartnershipcandidate](#)

Use the **lspartnershipcandidate** command to list the clustered systems available for setting up a partnership with the local system. This is a prerequisite for creating inter-system Metro or Global Mirror relationships.

[lsrconsistgrp](#)

Use the **lsrconsistgrp** command to return a concise list or a detailed view of remote copy consistency groups such as Metro Mirror, Global Mirror, or active-active consistency groups visible to the system.

lsrrelationship

Use the **lsrrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

lsrrelationshipcandidate

Use the **lsrrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

mkfcpartnership

Use the **mkfcpartnership** command to define partnerships using Fibre Channel (FC) or Fibre Channel over Ethernet (FCoE).

mkippartnership

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

mkpartnership (Discontinued)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrconsistgrp

Use the **mkrconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

mkrrelationship

Specify the **mkrrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrconsistgrp

Use the **rmrconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrrelationship

Use the **rmrrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

mkfcpartnership

Use the **mkfcpartnership** command to define partnerships using Fibre Channel (FC) or Fibre Channel over Ethernet (FCoE).

Syntax

►► mkfcpartnership — -linkbandwidthmbits — *link_bandwidth_in_mbps* →

Parameters

-linkbandwidthmbits *link_bandwidth_in_mbps*

(Required) Specifies the aggregate bandwidth of the Remote Copy (RC) link between two clustered systems (systems in megabits per second (Mbps)). It is a numeric value from 1 to 1000000.

Note: Remote copy includes Metro Mirror and Global Mirror.

This value remains the same after a system update.

Note: If the specified value is non-zero, the combination of both the **-backgroundcopyrate** and the **-linkbandwidthmbits** values must result in a background copy bandwidth of at least 8 Mbps.

-backgroundcopyrate *percentage*

(Optional) Specifies the maximum percentage of aggregate link bandwidth that can be used for background copy operations. It is a numeric value from 0 to 100, and the default value is 50, which means that a maximum of 50% of the aggregate link bandwidth can be used for background copy operations. This parameter can be specified without stopping the partnership.

Note: If the specified value is non-zero, the combination of both the **-backgroundcopyrate** and the **-linkbandwidthmbits** values must result in a background copy bandwidth of at least 8 Mbps.

remote_system_id / **remote_system_name**

(Required) Specifies the remote system ID or name of a partnership. The specified value must match one of the system IDs or names returned after issuing **lspartnershipcandidate**.

Description

This command defines FC-based or FCoE-based partnerships. However, all existing partnerships are automatically updated to FC partnerships, any invocation of this command is applicable only to FC-based partnerships, and all partnerships created are FC-based partnerships.

An invocation example

```
mkfcpartnership -linkbandwidthmbits 100 -backgroundcopyrate 50 remote-system-2
```

The resulting output:

```
No feedback
```

An invocation example

```
mkfcpartnership -linkbandwidthmbits 1024 -backgroundcopyrate 25 remote-system-3
```

The resulting output:

```
No feedback
```

Use the **lsrconsistgrp** command to return a concise list or a detailed view of remote copy consistency groups such as Metro Mirror, Global Mirror, or active-active consistency groups visible to the system.

[lsrrelationship](#)

Use the **lsrrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

[lsrrelationshipcandidate](#)

Use the **lsrrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

[lsrrelationshipprogress](#)

Use the **lsrrelationshipprogress** command to display the progress of the background copy of a Metro Mirror, Global Mirror, or active-active relationship as a percentage. When the initial background copy process for a relationship completes, a null value is displayed for the progress of that relationship.

[mkippartnership](#)

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

[mkpartnership \(Discontinued\)](#)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrcconsistgrp

Use the **mkrcconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

mkrcrelationship

Specify the **mkrcrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrcconsistgrp

Use the **rmrcconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrcrelationship

Use the **rmrcrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

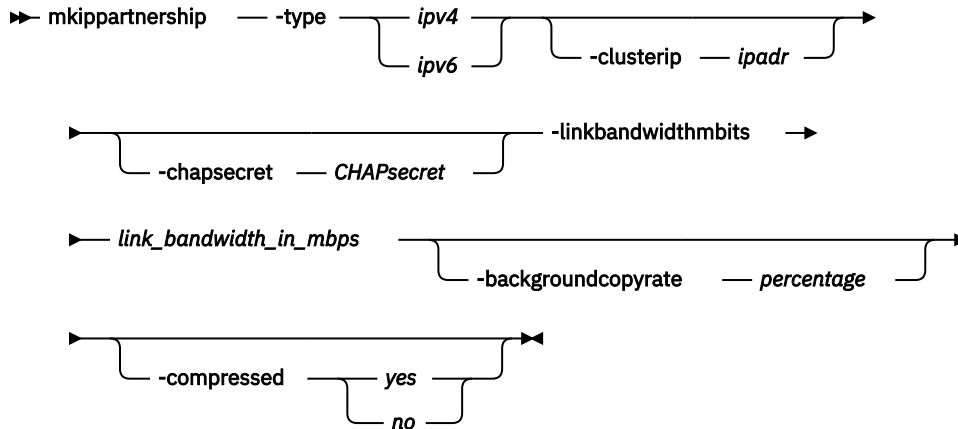

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

mkippartnership

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

Syntax

Parameters

-type *ipv4* / *ipv6*

(Required) Specifies the Internet Protocol (IP) address format for the partnership using either of the following case-sensitive strings:

- *ipv4* for Internet Protocol Version 4 (IPv4)
- *ipv6* for Internet Protocol Version 6 (IPv6)

All Transmission Control Protocol (TCP) Remote Copy (RC) connections between the primary and remote clustered systems (systems) are created using specific IP addresses.

Note: Remote copy includes Metro Mirror and Global Mirror.

Partnership creation fails if the Internet Protocol (IP) address types specified for either primary or remote systems are not the same.

-clusterip *ipadr*

(Required) Specifies the partner system IP address, either *ipv4* or *ipv6*. Systems connected over IP links are not displayed by **lspartnershipcandidate** before executing **mkippartnership**. This does not apply to FC-based or FCoE-based connections.

-chapsecret *CHAPsecret*

(Optional) Specifies the Challenge-Handshake Authentication Protocol (CHAP) secret of the partner system. The maximum size of the CHAP secret is eighty alphanumeric characters.

-linkbandwidthmbits *link_bandwidth_in_mbps*

(Required) Specifies the aggregate bandwidth of the RC link between two clustered systems (systems) in megabits per second (Mbps). It is a numeric value from 1 to 100000.

Important: For partnerships over IP links with compression, this parameter specifies the aggregate bandwidth after the compression had been applied to the data. Do not set this parameter higher than the physical link bandwidth multiplied by the (carefully rounded down) compression factor.

This parameter can be specified without stopping the partnership.

Note: If the specified value is non-zero, the combination of both the **-backgroundcopyrate** and the **-linkbandwidthmbits** values must result in a background copy bandwidth of at least 8 Mbps.

-backgroundcopyrate percentage

(Optional) Specifies the maximum percentage of aggregate link bandwidth that can be used for background copy operations. It is a numeric value from 0 to 100, and the default value is 50, which means that a maximum of 50% of the aggregate link bandwidth can be used for background copy operations.

Note: If the specified value is non-zero, the combination of both the **-backgroundcopyrate** and the **-linkbandwidthmbits** values must result in a background copy bandwidth of at least 8 Mbps.

-compressed yes / no

(Optional) Specifies whether compression is enabled for this partnership. The default value is no.

Description

This command defines a new partnership created over Internet Protocol (IP) links. A remote system IP must be specified so its IP ports are enabled for data replication. RC sessions can then be created between the two partners.

In FC-based or FCoE-based partnerships, the partner system must first be a partnership candidate (displayed by **lspartnership**). Then it can become part of a partnership, created specifying **mkfcpartnership** with the remote system ID or name.

The **lspartnershipcandidate** command displays partnership candidates.

For IP partnerships, specifying **mkippartnership** with the cluster IP address and CHAP secret of the partner creates the partnership.

All TCP connections are established using either IPv4 or IPv6, and it cannot be a mix of the two IP address types.

Both systems in a partnership must have at least one IP address from an identical replication group to establish RC partnerships. Replication groups are numeric values that specify the pools of local IP addresses that establish Remote Copy partnerships with pools of IP addresses configured on the partner system.

An invocation example

```
mkippartnership -type ipv4 -clusterip 192.168.32.19  
                -chapsecret mychapsecret -linkbandwidthmbits 100 -backgroundcopyrate 50
```

The resulting output:

```
No feedback
```

An invocation example

```
mkippartnership -type ipv6 -clusterip fe80::200:f8ff:fe21:67cf  
                -chapsecret mychapsecret -linkbandwidthmbits 1024 -backgroundcopyrate 25
```

The resulting output:

```
No feedback
```

An invocation example creating a compressed IP replication link

```
mkippartnership -type ipv4 -clusterip 192.168.32.19 -chapsecret mychapsecret -linkbandwidthmbits 100 -  
backgroundcopyrate 50 -compressed yes
```

The resulting output:

```
No feedback
```

rmrcrelationship

Use the **rmrcrelationship** command to delete an existing remote copy relationship.

starttrcconsistgrp

Specify **startcrconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startcrrelationship

Use the **startcrrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stopcrrelationship -access**.

stopcrconsistgrp

Use the **stopcrconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stopcrrelationship

Use the **stopcrrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchcrconsistgrp

Use the **switchcrconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

switchcrrelationship

Use the **switchcrrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

mkcrconsistgrp

Use the **mkcrconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

Syntax

```
➤ mkcrconsistgrp -name new_name [-cluster cluster_id | cluster_name]
```

Parameters

-name *new_name*

(Optional) Specifies a name for the new consistency group.

-cluster *cluster_id* | *cluster_name*

(Optional) Specifies the name or ID of the remote system. If **-cluster** is not specified, a consistency group is created only on the local system.

Description

This command creates a new consistency group. The ID of the new group is displayed after the command processes. The name must be unique across all consistency groups that are known to the systems within this consistency group. If the consistency group involves two system, the systems must be in communication throughout the create process.

The new consistency group does not contain any relationships and is in an empty state. You can add Metro Mirror, Global Mirror, or active-active relationships to the group by using the **chrrelationship** command.

Remember: Names representing remote copy consistency groups relationships are restricted to 15 characters in length (not sixty-three for an extended character set).

An invocation example

```
mkrcconsistgrp -name rc_testgrp
```

The resulting output:

```
RC Consistency Group, id [255], successfully created
```

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrcconsistgrp

Use the **rmrcconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrcrelationship

Use the **rmrcrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

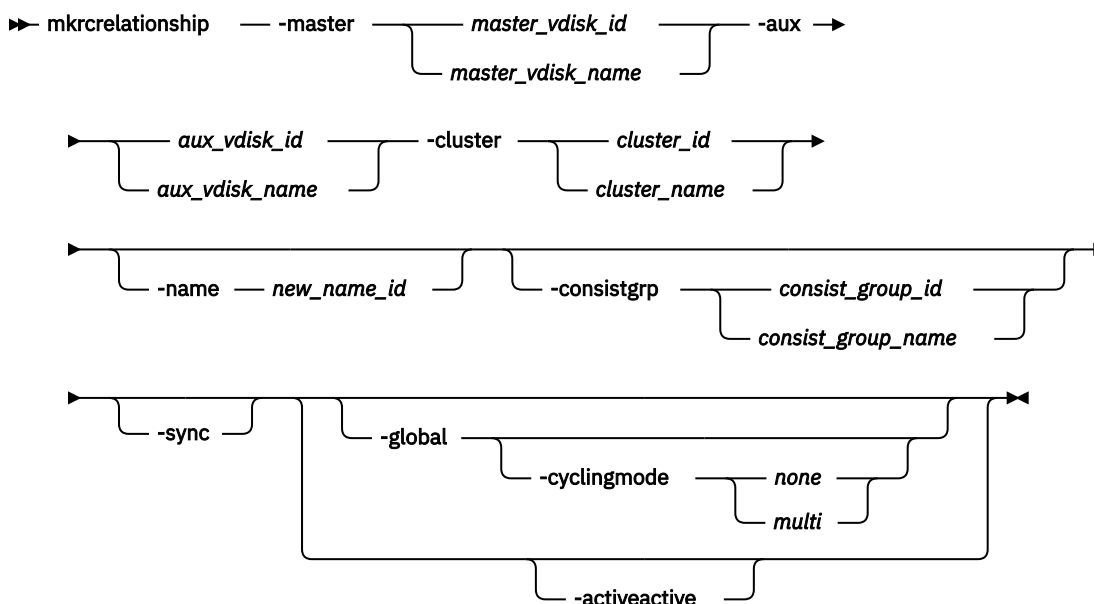

switchrcrelationship

Use the **switchcrrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

mkrelationship

Specify the **mkcrrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

Syntax

Parameters

```
-master master vdisk id | master vdisk name
```

(Required) Specifies the ID or name of the *master_vdisk_id* or *master_vdisk_name*.

If a new remote copy relationship is mapped to a host of type `hide_secondary`, the secondary volume is not presented to the host; however, it is mapped for configuration purposes. The secondary volume is presented to the host if the:

- Host type is changed to a type other than `hide_secondary`
- Remote copy relationship is stopped by specifying `stopprcrelationship -access`
- Volume is no longer a secondary volume because the remote copy relationship is deleted or switched

-aux aux vdisk id / aux vdisk name

(Required) Specifies the ID or name of the aux_vdisk_id or aux_vdisk_name.

-cluster *cluster_id / cluster_name*

(Required) Specifies the ID or name of the remote cluster.

- If you are creating an intrasystem relationship, enter the ID of the local system. The volumes in the relationship must belong to the same I/O group within the system.
- If you are creating an intersystem relationship, enter the ID of the remote system. To create a relationship in two different systems, the systems must be connected at the time that the **mkrcrelationship** command is received.

-name *new name id*

(Optional) Specifies a label to assign to the relationship.

-consistgrp *consist_group_id* / *consist_group_name*

(Optional) Specifies a consistency group that this relationship joins. If you do not supply the **-consistgrp** parameter, the relationship is created as a stand-alone relationship that can be started, stopped, and switched on its own.

Note: Metro Mirror, Global Mirror, and active-active relationships cannot belong to the same consistency group. When the first relationship is added to the consistency group, the group takes on the same type as the relationship. Then, only relationships of that type can be added to the consistency group.

-sync

(Optional) Specifies that you want the system to create a synchronized relationship. The **-sync** parameter guarantees that the master and auxiliary disks contain identical data at the point that the relationship is created. You must ensure that the auxiliary disk is created to match the master disk and that no input transactions take place to either disk before you issue the create command. The initial background synchronization is skipped.

-global

(Optional) Specifies that you want the system to create a new Global Mirror relationship. If you do not specify the **-global** parameter, a Metro Mirror relationship is created instead. You cannot specify this keyword with **-activeactive**.

-cyclingmode *none* / *multi*

(Optional) Specifies the behavior of Global Mirror for this relationship.

- Specifying *none*, the default, gives identical behavior to Global Mirror in previous versions of SAN Volume Controller .
- Specifying *multi* uses the cycling protocol.

The default cycle period is 300 seconds. The cycle period can be modified after the relationship is created by using the **chrcrelationship** command. To start a relationship with *cycling_mode* set to *multi*, change volumes must be defined for the relationship.

Important: This parameter must be specified with **-global**.

-activeactive

(Optional) Specifies that the relationship is created in an active-active mode. You cannot specify this keyword with **-global** (this parameter defaults to a Metro Mirror relationship that is being created).

Description

This command creates a new Global Mirror, Metro Mirror, or active-active relationship. A Metro Mirror relationship defines the relationship between two volumes. One volume is a master volume and the other volume is an auxiliary volume. This relationship persists until deleted. The auxiliary volume must be identical in size to the master volume or the command fails. This command also returns the new relationship ID.

The master and auxiliary cannot be in an existing relationship. Any defined FlashCopy mappings that have the proposed master volume as the target of the FlashCopy mapping must be using the same I/O group as the master volume. Any defined FlashCopy mappings that have the proposed auxiliary volume as the target of the FlashCopy mapping must be using the same I/O group as the auxiliary volume.

Note: You cannot create a remote copy relationship with this command if the auxiliary volume is an active FlashCopy mapping target. If the I/O group has enough bitmap space available to allocate for remote copy and the allocated space for the remote copy is not large enough to accommodate the new relationship, space is automatically added. (Remote copy includes Global Mirror, Metro Mirror, and active-active relationships.)

Note: You cannot use this command if cloud snapshot is enabled on the volume or the volume owner type is *cloud_backup*.

Metro Mirror relationships use one of the following copy types:

- A Metro Mirror copy ensures that updates are committed to both the primary and secondary volumes before the copy sends confirmation of I/O completion to the host application. This ensures that the secondary volume is synchronized with the primary volume if a failover operation is performed.
- A Global Mirror copy allows the host application to receive confirmation of I/O completion before the updates are committed to the secondary volume. If a failover operation is performed, the host application must recover and apply any updates that were not committed to the secondary volume.

You can optionally give the relationship a name. The name must be a unique relationship name across both systems.

The relationship can optionally be assigned to a consistency group. A consistency group ensures that a number of relationships are managed so if the relationships disconnect, the data in all relationships within the group is in a consistent state. For example, the state can be important in a database application where data files and log files are stored on separate volumes and consequently are managed by separate relationships.

Remember: In the event of a disaster, the primary and secondary sites might become disconnected.

As the disconnection occurs and the relationships stop copying data from the primary to the secondary site, there is no assurance that updates to the two separate secondary volumes stop in a consistent manner if the relationships that are associated with the volumes do not belong to a consistency group.

For proper database operation, it is important that updates to the log files and the database data are made in a consistent and orderly fashion. It is crucial in this example that the log file volume and the data volume at the secondary site are in a consistent state. This can be achieved by putting the relationships that are associated with these volumes into a consistency group. Both Metro Mirror and Global Mirror processing ensure that updates to both volumes at the secondary are stopped, leaving a consistent image based on the updates that occurred at the primary site.

If you specify a consistency group, both the group and the relationship must be created by using the same master system and the same auxiliary system. The relationship must not be a part of another consistency group. If the consistency group is empty, it acquires the type of the first relationship that is added to it. Therefore, each subsequent relationship that you add to the consistency group must have the same type.

If the consistency group is not empty, the consistency group and the relationship must be in the same state. If the consistency group is empty, it acquires the state of the first relationship that is added to it. If the state has an assigned copy direction, the direction of the consistency group and the relationship must match that direction.

If you do not specify a consistency group, a stand-alone relationship is created.

If you specify the **-sync** parameter, the master and auxiliary volumes contain identical data at the point when the relationship is created. You must ensure that the auxiliary is created to match the master and that no data movement occurs to either volume before you issue the **mkrcrelationship** command.

If you specify the **-global** parameter, a Global Mirror relationship is created. Otherwise, a Metro Mirror relationship is created instead.

The volumes that are specified on the **-master** and **-aux** parameters cannot be master or auxiliary volumes in an existing relationship.

If you specify **-activeactive**:

- The system that is specified with **-cluster** must be the local system.
- **-global** must not be specified.
- The volume that is specified with **-master** must:
 - Be in an I/O group with both nodes that have the same site name and site ID
 - Have all volume copies stored in storage pools in the same site as the volume's I/O group
 - Not be the target of a FlashCopy mapping

- Not be the source of any FlashCopy mappings to volumes in a different site or by using bitmap memory from nodes in a different site (but the volume can be the source of a FlashCopy mapping in which the target volume and map are in the same site)
- The volume that is specified with **-aux** must:
 - Be part of an I/O group with a different site ID and site name than the master volume (with no volume host mappings that are defined)
 - Have all volume copies stored in storage pools in the same site as the volume's I/O group
 - Not be the target of a FlashCopy mapping
 - Not be the source of any FlashCopy mappings to volumes in a different site or by using bitmap memory from nodes in a different site (but the volume can be the source of a FlashCopy mapping in which the target volume and map are in the same site)

Access the data stored on these volumes by accessing the volume you specify using the **-master** parameter. Both I/O groups of the volumes that are specified by the **-master** and **-aux** parameters have a local physical copy and cache, allowing access (by using the master volume ID) whether the auxiliary volume's site is available or not.

Remember: This command cannot be used on a volume that is owned by a file system.

Note: This command fails if you attempt to create a Remote Copy relationship with a secondary volume that is in a protected storage pool on a secondary system with volume protection enabled and the secondary volume has received host I/O in the volume protection time period. This check is completed only when both systems are running a software level that includes this validation.

An invocation example

```
mkrcrelationship -master vdisk1 -aux vdisk2 -name rccopy1
-cluster 0000020063432AFD
```

The resulting output:

```
RC Relationship, id [28], successfully created
```

An invocation example

```
mkrcrelationship -master vdiskA -aux vdiskB -cluster clusterB -name new_rel -global -
cyclingmode multi
```

The resulting output:

```
RC Relationship, id [28], successfully created
```

An invocation example

```
mkrcrelationship -master volA -aux volB -cluster localCluster -activeactive
```

The resulting output:

```
RC Relationship, id [28], successfully created
```

[chpartnership](#)

Use the **chpartnership** command to modify the bandwidth of the partnership between the local system and the remote system that is specified in the command. This affects the bandwidth that is available for background copy in a system partnership by either Metro Mirror or Global Mirror operations. Additionally, use this command to disable and re-enable the partnership, which allows the local system to be disconnected and then reconnected to the remote system.

[chrconsistgrp](#)

Use the **chrcconsistgrp** command to modify attributes of an existing Metro Mirror, Global Mirror, or active-active consistency group, such as changing the name of a consistency group.

chrcrelationship

Use the **chrcrelationship** command to modify certain attributes of an existing relationship, such as to add a relationship to a consistency group to remove a relationship from a consistency group, and to change the name of the relationship. You can change one attribute at a time.

lspartnership

Use the **lspartnership** command to display a concise or detailed view of the current clustered systems (systems) that are associated with the local system.

lspartnershipcandidate

Use the **lspartnershipcandidate** command to list the clustered systems available for setting up a partnership with the local system. This is a prerequisite for creating inter-system Metro or Global Mirror relationships.

lsrcconsistgrp

Use the **lsrcconsistgrp** command to return a concise list or a detailed view of remote copy consistency groups such as Metro Mirror, Global Mirror, or active-active consistency groups visible to the system.

lsrcrelationship

Use the **lsrcrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

lsrcrelationshipcandidate

Use the **lsrcrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

lsrcrelationshipprogress

Use the **lsrcrelationshipprogress** command to display the progress of the background copy of a Metro Mirror, Global Mirror, or active-active relationship as a percentage. When the initial background copy process for a relationship completes, a null value is displayed for the progress of that relationship.

mkfcpartnership

Use the **mkfcpartnership** command to define partnerships using Fibre Channel (FC) or Fibre Channel over Ethernet (FCoE).

mkippartnership

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

mkpartnership (Discontinued)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrcconsistgrp

Use the **mkrcconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrcconsistgrp

Use the **rmrcconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrcrelationship

Use the **rmrcrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

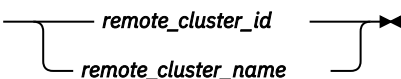

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

Syntax

➔ **rmpartnership** 

Parameters

remote_cluster_id / remote_cluster_name

(Required) Specifies the system ID or the name of the remote system.

Description

This command deletes one half of a partnership on a system. To remove the entire partnership, you must run the command twice, once on each system.

Attention: Before running the **rmpartnership** command, you must remove all relationships and groups that are defined between the two systems. To display system relationships and groups, run the **lsrcrelationship** and **lsrcconsistgrp** commands. To remove the relationships and groups that are defined between the two systems, run the **rmrcrelationship** and **rmrcconsistgrp** commands.

An invocation example

```
rmpartnership cluster1
```

The resulting output:

```
No feedback
```

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrcconsistgrp

Use the **mkrcconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

mkrcrelationship

Specify the **mkrcrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmrcconsistgrp

Use the **rmrcconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrcrelationship

Use the **rmrcrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

rmrcconsistgrp

Use the **rmrcconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

Syntax

➔ **rmrcconsistgrp** 

Parameters

-force

(Optional) Specifies that you want the system to remove any relationship that belongs to a group before the consistency group is deleted. The relationship itself is not deleted; it becomes a stand-alone relationship.

Note: The **-force** parameter must be used to delete a consistency group when the consistency group has any Metro Mirror, Global Mirror, or active-active relationship that is associated with it. If you do not use the **-force** parameter, the command fails.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

rc_consist_group_id | rc_consist_group_name

(Required) Specifies the ID or the name of the consistency group to delete.

Description

This command deletes the specified consistency group. You can issue this command for any existing consistency group. If the consistency group is disconnected at the time that the command is issued, the consistency group is only deleted on the cluster that is connected. When the clusters reconnect, the consistency group is automatically deleted on the other cluster. Alternatively, if the clusters are disconnected, and you still want to remove the consistency group on both clusters, you can issue the **rmrconsistgrp** command separately on both of the clusters.

If the consistency group is not empty, the **-force** parameter is required to delete the group. Specifying the **-force** parameter removes the relationships from the consistency group before the group is deleted. These relationships become stand-alone relationships. The state of these relationships is not changed by the action of removing them from the consistency group.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

An invocation example

```
rmrconsistgrp rctestone
```

The resulting output:

```
No feedback
```

mkpartnership (Discontinued)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrconsistgrp

Use the **mkrconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

mkrrelationship

Specify the **mkrrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrrelationship

Use the **rmrrelationship** command to delete an existing remote copy relationship.

startcrconsistgrp

Specify **startcrconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startcrrelationship

Use the **startcrrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stopcrrelationship -access**.

stopprconsistgrp

Use the **stopprconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stopprrelationship

Use the **stopprrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrconsistgrp

Use the **switchrconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

switchrrelationship

Use the **switchrrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

rmrrelationship

Use the **rmrrelationship** command to delete an existing remote copy relationship.

Syntax

➔ **rmrrelationship** 

Parameters

-force

(Optional) Specifies that the relationship must be deleted even if it results in the secondary volume that contains inconsistent data. This parameter applies only to active-active relationships or Global Mirror relationships that use multi cycling mode.

rc_rel_id / rc_rel_name

(Required) Specifies the ID or the name of the relationship.

Description

This command deletes the relationship that is specified. Deleting a relationship removes the logical relationship between the two volumes but it does not affect the volumes themselves.

If the relationship is disconnected at the time that the command is issued, the relationship is only deleted on the system where the command is being run. When the systems reconnect, the relationship is automatically deleted on the other system. Alternatively, if the systems are disconnected and if you still want to remove the relationship on both systems, you can issue the **rmrrelationship** command independently on both of the systems.

If a relationship is active-active or is a Global Mirror relationship that uses multicycling mode, and you attempt to delete the relationship without enabling access first, specifying **rmrrelationship** might fail with an error because the relationship does not currently have a fully consistent secondary volume. Specifying **-force** overrides this test. This is not the default behavior, and you can quiesce and delete the relationship in order to use the secondary volume's data immediately. If the map is still performing the background copy to migrate data from the change volume to the secondary volume, the changed volume and associated FlashCopy mappings remain defined when **rmrrelationship** completes. The FlashCopy mappings are deleted after the background copy completes, and the change volume becomes unusable again.

If you delete an inconsistent relationship, the secondary volume becomes accessible even though it is still inconsistent. This case is the only one in which Metro Mirror, Global Mirror, or HyperSwap does not inhibit access to inconsistent data.

An invocation example

```
rmrcrelationship rccopy1
```

The resulting output:

```
No feedback
```

[chrcrelationship](#)

Use the **chrcrelationship** command to modify certain attributes of an existing relationship, such as to add a relationship to a consistency group to remove a relationship from a consistency group, and to change the name of the relationship. You can change one attribute at a time.

[lspartnership](#)

Use the **lspartnership** command to display a concise or detailed view of the current clustered systems (systems) that are associated with the local system.

[lspartnershipcandidate](#)

Use the **lspartnershipcandidate** command to list the clustered systems available for setting up a partnership with the local system. This is a prerequisite for creating inter-system Metro or Global Mirror relationships.

[lsrconsistgrp](#)

Use the **lsrconsistgrp** command to return a concise list or a detailed view of remote copy consistency groups such as Metro Mirror, Global Mirror, or active-active consistency groups visible to the system.

[lsrcrelationship](#)

Use the **lsrcrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

[lsrcrelationshipcandidate](#)

Use the **lsrcrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

[lsrcrelationshipprogress](#)

Use the **lsrcrelationshipprogress** command to display the progress of the background copy of a Metro Mirror, Global Mirror, or active-active relationship as a percentage. When the initial background copy process for a relationship completes, a null value is displayed for the progress of that relationship.

[mkfcpartnership](#)

Use the **mkfcpartnership** command to define partnerships using Fibre Channel (FC) or Fibre Channel over Ethernet (FCoE).

[mkippartnership](#)

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

mkpartnership (Discontinued)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrconsistgrp

Use the **mkrconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

mkrrelationship

Specify the **mkrrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrconsistgrp

Use the **rmrconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

startrconsistgrp

Specify **startrconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrelationship

Use the **startrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprelationship -access**.

stoprconsistgrp

Use the **stoprconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprelationship

Use the **stoprelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrconsistgrp

Use the **switchrconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

switchrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

Syntax

Parameters

-primary master / aux

(Optional) Specifies the copy direction by defining whether the master or auxiliary disk becomes the primary (source). This parameter is required when the primary is undefined if, for example, the consistency group is in the Idling state.

-force

(Optional) Specifies that you want the system to process the copy operation even if it might lead to a temporary loss of consistency while synchronization occurs. This parameter is required if the consistency group is in the ConsistentStopped state, but is not synchronized or is in the idling state - except if consistency protection is configured.

-clean

(Optional) Specifies that the volume indicated as secondary is clean for each of the relationships that belong to the group. Any changes that are made on the secondary volume are ignored, and only changes made on the clean primary volume are considered during synchronization of the primary and secondary disks. The consistency group must be in an Idling (connected) state for this parameter to work.

Attention: Specify this parameter when all data changed on the secondary volumes while the consistency group was in the idling state matches the state of the primary volumes when the consistency group was stopped. Otherwise, relationships that are not consistent are reported as consistent. Once this has been done, there is no method to determine whether these volumes ever reach a true consistent state until a full background copy can be carried out again.

rc_consist_group_id / rc_consist_group_name

(Required) Specifies the ID or name of the consistency group to start.

Description

This command starts a Global Mirror, Metro Mirror, or active-active stand-alone consistency group. You cannot use this command to start a remote copy relationship if the primary volume is a target volume of a prepared FlashCopy mapping.

This command can be issued only to a consistency group that is connected. For a consistency group that is idling, this command assigns a copy direction (primary and secondary roles) and begins the copy process. Otherwise, this command restarts a previous copy process that was stopped either by a stop command or by an I/O error.

Note: You cannot start a consistency group if it contains a relationship with primary and secondary volumes that are different sizes.

If you specify `stoprcconsistgrp -access` on an existing remote copy relationship that is restarted and the resultant secondary volume (depending on the choice of primary) is mapped to a host of type `hide_secondary`, that volume is not presented to the host. This is true even though it is mapped for configuration purposes. The mapped volumes are presented to the host if the:

- Host type is changed to a type other than `hide_secondary`
- Remote copy relationship is stopped and you specify `stoprcconsistgrp -access`
- Volume ceases to be a secondary volume because the remote copy relationship is being deleted or switched

If the resumption of the copy process leads to a period when the relationship is not consistent, then you must specify the **-force** parameter when you restart the relationship. This situation can arise if the relationship is stopped and then further input transactions is performed on the original primary disk of the relationship. When you use the **-force** parameter in this situation, the data on the secondary disk is not usable (because it is inconsistent) in a disaster recovery circumstance.

In the idling state, you must provide the **-primary** parameter. In other connected states, you can provide the **-primary** parameter, but it must match the existing setting.

The **-force** parameter is required if consistency would be lost by starting a copy operation. This can occur if write operations on either primary or secondary volumes take place since the `ConsistentStopped` or `idling` state occurred. If the command is issued without the **-force** parameter in such circumstances, the command fails. In general, the **-force** parameter is required if the group is in one of the following states:

- `consistent_stopped` but not synchronized (`sync=out_of_sync`)
- `i` but not synchronized (`sync=out_of_sync`)

The **-force** parameter is not required if the group is in `inconsistent_stopped`, `inconsistent_copying`, or `consistent_synchronized` state. The command does not fail if you specify the **-force** parameter.

When you configure a secondary change volume on all relationships in a consistency group, the consistency group changes to `consistent_copying` state during resynchronization. If you specify **startrcconsistgrp** for a consistency group that is in an `idling` state, consistency protection is disabled if any of the secondary volumes are written to. This means that you must specify the **-force** parameter.

The **-clean** parameter is used when a Global Mirror or Metro Mirror group is started and the secondary volumes in this group are assumed to be clean, which means that any changes that are made at the secondary are ignored and only changes that are made at the primary are considered when synchronizing the primary and secondary volumes. The **-clean** parameter can be used in the following scenario:

1. You specify the **-sync** parameter to create a consistency group. It does not matter if the primary and secondary contain the same data - even though the use of the **-sync** parameter implies that is true.
2. You specify `stoprcconsistgrp -access`. This permits access to the secondary disk. Change recording begins at the primary.
3. You copy and load an image of the primary disk onto to the secondary disk. It is permissible to allow updates to the primary disk during the image copy as this image can be only a fuzzy image of the primary disk.
4. You specify the **startrcconsistgrp** command with the **-primary master**, **-force**, and **-clean** parameters. The auxiliary disk is marked as clean and changes on the master disk that occur since the relationship was stopped are copied to the auxiliary disk.
5. A background copy completes and the relationships in the group become consistent and synchronized.

After you restart a consistency group in either of these states (`Idling` or `multi`), the data on the secondary volumes is not usable for disaster recovery until the consistency group becomes consistent.

A Global Mirror consistency group with a `cycling_mode` of `multi` in either of these states does not require the **-force** parameter because consistent secondary images are retained. However, if such a consistency group is in `idling` state and written data is received at any secondary volume in the consistency group, the **-force** flag is still required, because the secondary volumes have a divergent image that cannot represent a consistent earlier state.

A Global Mirror relationship with a cycling mode of:

- *none* uses the non-cycling Global Mirror algorithm
- *multi* must have a change volume that is configured at the primary volume (or the command fails)
- *multi* must also have a change volume that is configured at the secondary volume (or the command fails)
- *multi* performs multiple cycles of cycling

After you create a background copy the relationship remains in copying state, waiting for the remainder of the period time to expire before you perform a new cycle. If the secondary change volume is deconfigured when the background copy completes, the relationship stops as if there is no cycle period.

Relationships that are active-active must have a state of `idling` to be started.

An invocation example

```
starttrconsistgrp rccopy1
```

The resulting output:

```
No feedback
```

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

Syntax

Parameters

-primary master / aux

(Optional) Specifies the copy direction by defining whether the master or auxiliary disk becomes the primary (source). This parameter is required when the primary is undefined if, for example, the relationship is in the idling state.

-force

(Optional) Specifies that you want the system to process the copy operation even if it might lead to a temporary loss of consistency while synchronization occurs. This parameter is required if the relationship is in the ConsistentStopped state, but is not synchronized or in idling state - except if consistency protection is configured.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

-clean

(Optional) Specifies that the volume that is to become a secondary is clean. Any changes that are made on the secondary volume are ignored, but changes made on the clean primary volume are considered when synchronizing the primary and secondary disks. The relationship must be in an Idling (connected) state for this parameter to work.

Attention: This flag must be used only if all data changed on the secondary volumes while the consistency group was in the idling state matches the state of the primary volumes when the consistency group was stopped. Otherwise, relationships that are not consistent are reported as consistent. When this completes, there is no method to determine whether these volumes ever reach a true consistent state until a full background copy can be carried out again.

rc_rel_id / rc_rel_name

(Required) Specifies the ID or name of the relationship that you want to start in a stand-alone relationship.

Description

The **startcrrelationship** command starts a stand-alone relationship. The command fails if it is used to start a relationship that is part of a consistency group.

Note: You cannot start a relationship if the primary and secondary volumes are different sizes.

This command can be specified only to a relationship that is connected. For a relationship that is idling, this command assigns a copy direction (primary and secondary roles) and begins the copy process. Otherwise, this command restarts a previous copy process that was stopped either by a stop command or by some I/O error.

Note: A command in idling state is rejected if any of the indicated secondary volumes is the target of an existing FlashCopy map.

If the FlashCopy mapping is active, the remote copy cannot be started.

If an existing remote copy relationship is stopped by specifying **stopcrrelationship -access** but is restarted and the resultant secondary volume (depending on the choice of primary) is mapped to a host of type **hide_secondary**, that volume is not presented to the host. This is true even though it is mapped for configuration purposes. The mapped volumes are presented to the host if the:

- Host type is changed to a type other than **hide_secondary**
- Remote copy relationship is stopped by specifying **stopcrrelationship -access**
- Volume ceases to be a secondary volume because the remote copy relationship is being deleted or switched

In the idling state, you must provide the **-primary** parameter. In other connected states, you can provide the **-primary** parameter, but it must match the existing setting.

The **-force** parameter is required if consistency would be lost by starting a copy operation. This situation can occur if input transactions occur on either the primary or secondary volumes since the **ConsistentStopped** or **Idling** state occurred. This situation occurs when the relationship is in either of these states:

- **ConsistentStopped** but not synchronized
- **Idling** but not synchronized

After restarting a relationship in either of these states, the data on the secondary volume is not usable for disaster recovery until the relationship becomes consistent.

A Global Mirror relationship with a **cycling_mode** of **multi** in either of these states does not require the **-force** parameter because a consistent secondary image is retained. However, if such a relationship is in idling state and written data is received at the secondary volume, the **-force** flag is required because the secondary volume has a divergent image that cannot represent a consistent earlier state.

The **-force** parameter is not required if the relationship is in one of the following states:

- **InconsistentStopped**
- **InconsistentCopying**
- **ConsistentSynchronized**

However, the command does not fail if you specify the **-force** parameter.

You do not have to specify the **-force** parameter for relationships with configured secondary change volumes. If you specify **startcrrelationship** for an idling relationship, consistency protection is disabled if the secondary volume is written to. This means that you must specify the **-force** parameter.

A Global Mirror relationship with a cycling mode of:

- *none* uses the non-cycling Global Mirror algorithm
- *multi* must:
 - Use a change volume that is configured at the primary volume (or the command fails)
 - Use a change volume that is configured at the secondary volume (or the command fails)

- Perform multiple cycles of cycling

After you create a background copy the relationship remains in copying state, wait for the remainder of the period time to expire before you perform a new cycle. If the secondary change volume is unconfigured when the background copy completes, the relationship stops as if there is no cycle period.

Relationships that are active-active must have a state of idling to be started. (You must specify **-primary** to determine which of the master and auxiliary copies become the primary when you start an idling relationship.)

Use this command to:

- Restart the active-active relationship copy process and retain the historical disaster recovery copy that access is granted to (which might be used while the up-to-date copy was offline)
- Switch back to an up-to-date copy in the same state it was in before you specify `stopprrelationship -access`. Any changes that are made to the historical copy are discarded

Remember: If you switch back to the up-to-date copy, you might have to take host actions to prepare for the volume data that changes.

After you specify this command, if the secondary copy is not a historical copy of the primary relationship, it cannot be used for disaster recovery (and disaster recovery availability is restored after the copies are resynchronized). This situation can occur when:

- The new primary is the historical copy, which means the new secondary copy contains data that is from a later point in time than the data that the primary contains
- The secondary copy is the historical copy and is modified between specifying `stopprrelationship -access` and `starttrrelationship -primary` command (which means the secondary copy represents a divergent data image)

This command copies only the regions that are needed to resynchronize the two copies.

An invocation example

```
starttrrelationship rccopy1
```

The resulting output:

```
No feedback
```

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

Syntax

➔ stoprcconsistgrp 

Parameters

-access

(Optional) Allows write access to consistent secondary volumes in the consistency group.

rc_consist_group_id / rc_consist_group_name

(Required) Specifies the ID or the name of the consistency group to stop all processing for.

Description

This command applies to a consistency group. You can issue this command to stop processing on a consistency group that is copying from primary volumes to secondary volumes.

Note: You cannot stop a consistency group by using the **-access** parameter for a relationship if the primary and secondary volume are different sizes.

If the consistency group is in an inconsistent state, all copy operations stop and do not resume until you issue the **startrcconsistgrp** command. When a consistency group is in a consistent state (consistent_stopped, consistent_synchronized, consistent_copying, or consistent_disconnected), you can issue the **access** parameter with the **stoprcconsistgrp** command to enable write access to the secondary volumes within that group. For a consistency group in the consistent_synchronized state, this command causes a consistency freeze.

The consistent_copying state is a consistent state. A consistency group in this state changes to the consistent_stopped state if it receives a **stoprcconsistgrp** command. Because the secondary change volume holds the consistent image, a stopped consistent_copying relationship might not have its secondary change volume deconfigured. This can be achieved by enabling access or completing synchronization so the secondary disk contains a consistent image. A relationship in consistent_copying or consistent_stopped accepts **stoprcrelationship -access** transition to idling state.

The consistent image that is present on the change volume is made accessible at the secondary volume and after the command completes the secondary volume can serve host read and write I/O operations.

If you specify `stoprcconsistgrp -access` for a consistency group in a `consistent_copying` state the last consistent image on all the relationships in that group is restored. This process starts a FlashCopy mapping with the secondary change volume for the secondary volume in each relationship, which might cause the command to fail.

The relationship's data is from a different point in time than the consistency group's data if:

1. The consistency group is in a `consistent_copying` state
2. You add a relationship to the group after the state became `consistent_copying`

Therefore, the relationship and consistency group are not mutually consistent, and attempting to stop and enable access to the consistency group results in an error. To fix this, let a background copy complete so the consistency group becomes `consistent_synchronized`) or remove the inconsistent relationship from the consistency group before you enable access. If you stop the consistency group without the **-access** parameter, the consistency group becomes `consistent_stopped` but the secondary change volumes continue to retain a consistent image.

A FlashCopy background copy operation begins to migrate the data for the consistent image from the change volume to the secondary volume. While the background copy operation is in progress, the change volume for the secondary volume remains in use.

It might be necessary to process I/O before the reverse FlashCopy map can be triggered, causing the enable access command to time out. In this case, the relationship delays changing to `idling` until the reverse map starts and write access is available. Read access to the consistent data remains available.

To stop active-active consistency groups:

- You specify **-access**
- The relationship's state is `consistent_copying`
- The relationship's status is `primary_offline`

Specify `stoprcconsistgrp -access` to obtain host read or write access to a volume in an active-active consistency group that contains an older but consistent image that might be needed in a disaster recovery scenario (the relationship has a `consistent_copying` state).

Any remote copy secondary volumes that are mapped to hosts of type `hide_secondary` are presented to the host if you specify **-access**. Paths to those volumes are revealed to the host, and a logical unit number (LUN) inventory changed unit attention is raised to report their availability.

This table shows consistency group initial and final states:

<i>Table 111. stoprcconsistgrp consistency group states</i>		
Initial state	Final state	Notes®
inconsistent_stopped	inconsistent_stopped	If access is specified, the command is rejected.
inconsistent_copying	inconsistent_stopped	If access is specified, the command is rejected with no effect and the relationship remains in the <code>inconsistent_copying</code> state.
consistent_stopped	consistent_stopped	If access is specified, the final state is <code>idling</code> .
consistent_synchronized	consistent_stopped	If access is specified, the final state is <code>idling</code> . If access is not specified, the final state is <code>consistent_stopped</code> .

Table 111. stoprcconsistgrp consistency group states (continued)		
Initial state	Final state	Notes®
consistent_copying	consistent_stopped	If access is specified, the final state is idling. If access is not specified, the final state is consistent_stopped.
idling	idling	Remains in idling state whether access is specified or not.
idling_disconnected	unchanged	If specified without access , the relationship or group remains in idling_disconnected state. If the clustered systems reconnect, the relationship/group is in either inconsistent_stopped or consistent_stopped state.
inconsistent_disconnected	inconsistent_stopped	The command is rejected, with or without the access flag.
consistent_disconnected	consistent_stopped	The command is rejected if specified without access . If specified with access , the relationship or group moves to idling_disconnected.

An invocation example

```
stoprcconsistgrp rccopy1
```

[chpartnership](#)

Use the **chpartnership** command to modify the bandwidth of the partnership between the local system and the remote system that is specified in the command. This affects the bandwidth that is available for background copy in a system partnership by either Metro Mirror or Global Mirror operations. Additionally, use this command to disable and re-enable the partnership, which allows the local system to be disconnected and then reconnected to the remote system.

[chrconsistgrp](#)

Use the **chrconsistgrp** command to modify attributes of an existing Metro Mirror, Global Mirror, or active-active consistency group, such as changing the name of a consistency group.

[chrrelationship](#)

Use the **chrrelationship** command to modify certain attributes of an existing relationship, such as to add a relationship to a consistency group to remove a relationship from a consistency group, and to change the name of the relationship. You can change one attribute at a time.

[lspartnership](#)

Use the **lspartnership** command to display a concise or detailed view of the current clustered systems (systems) that are associated with the local system.

[lspartnershipcandidate](#)

Use the **lspartnershipcandidate** command to list the clustered systems available for setting up a partnership with the local system. This is a prerequisite for creating inter-system Metro or Global Mirror relationships.

lsrconsistgrp

Use the **lsrconsistgrp** command to return a concise list or a detailed view of remote copy consistency groups such as Metro Mirror, Global Mirror, or active-active consistency groups visible to the system.

lsrrelationship

Use the **lsrrelationship** command to return a concise list or a detailed view of remote copy relationships such as Metro Mirror, Global Mirror, or active-active relationships visible to the system.

lsrrelationshipcandidate

Use the **lsrrelationshipcandidate** command to list volumes that can form Metro Mirror, Global Mirror, or active-active relationships. You can list eligible volumes that are on the local or remote system.

lsrrelationshipprogress

Use the **lsrrelationshipprogress** command to display the progress of the background copy of a Metro Mirror, Global Mirror, or active-active relationship as a percentage. When the initial background copy process for a relationship completes, a null value is displayed for the progress of that relationship.

mkfcpartnership

Use the **mkfcpartnership** command to define partnerships using Fibre Channel (FC) or Fibre Channel over Ethernet (FCoE).

mkippartnership

Use the **mkippartnership** command to define a new partnership created over Internet Protocol (IP) links.

mkpartnership (Discontinued)

The **mkpartnership** command is deprecated. Use either the **mkfcpartnership** or **mkippartnership** command instead.

mkrconsistgrp

Use the **mkrconsistgrp** command to create a new, empty remote copy consistency group. If the **-cluster** parameter is not specified, the consistency group is created on the local system only.

mkrrelationship

Specify the **mkrrelationship** command to create a new Global Mirror, Metro Mirror, or active-active relationship with volumes in the same system, forming an intrasystem Metro Mirror relationship or intersystem relationship (if it involves more than one system).

rmpartnership

Use the **rmpartnership** command to remove a Metro Mirror or Global Mirror partnership on one system. Because the partnership exists on both systems, it is necessary to run this command on both systems to remove both sides of the partnership. If the command is run on only one system, the partnership enters a partially configured state on the other system.

rmrconsistgrp

Use the **rmrconsistgrp** command to delete an existing Metro Mirror, Global Mirror, or active-active consistency group.

rmrrelationship

Use the **rmrrelationship** command to delete an existing remote copy relationship.

startrcconsistgrp

Specify **startrcconsistgrp** to start the Global Mirror, Metro Mirror, or active-active consistency group copy process, set the direction of copy if it is undefined, and optionally mark the secondary volumes of the consistency group as clean.

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the

relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify `stopprrelationship -access`.

stopprrelationship

Use the **stopprrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

stopprrelationship

Use the **stopprrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

Syntax

➔ stopprrelationship 

Parameters

-access

(Optional) Specifies that the system allow write access to a consistent secondary volume.

rc_rel_id / rc_rel_name

(Required) Specifies the ID or the name of the relationship to stop all processing for.

Description

The **stopprrelationship** command applies to a stand-alone relationship. The command is rejected if it is addressed to a relationship that is part of a consistency group. You can issue this command to stop a relationship that is copying from primary to secondary volumes.

Note: You cannot stop a relationship by using the **-access** parameter for a relationship if the primary and secondary volumes are different sizes.

If the relationship is in an inconsistent state, any copy operation stops and does not resume until you issue a **starttrrelationship** command. For a relationship in the `consistent_synchronized` state, this command causes a consistency freeze.

When a relationship is in a consistent state – in the `consistent_stopped`, `consistent_synchronized`, `consistent_copying`, or `consistent_disconnected` state – you can use the **access** parameter to enable write access to the secondary volume. [Table 112 on page 1294](#) provides consistency group initial and final states.

The `consistent_copying` state is a consistent state. A relationship in `consistent_copying` state transitions to `consistent_stopped` state when you specify **stopprrelationship**. Because the secondary change volume holds the consistent image, a stopped `consistent_copying` relationship might not have its secondary change volume deconfigured. This can be achieved by enabling access or completing synchronization so the secondary disk contains a consistent image. A relationship in `consistent_copying` or `consistent_stopped` accepts **stopprrelationship -access** transition to idling state.

The consistent image that is present on the change volume is made accessible at the secondary volume. After the command completes, the secondary volume can serve host read and write I/O.

A FlashCopy background copy operation migrates the data for the consistent image from the change volume to the secondary volume. While the background copy operation is in progress, the change volume for the secondary volume remains in use.

The enable access command can time out if there is I/O to process before the reverse FlashCopy map can be triggered. In this case, the relationship delays the transition to `idling` until the reverse map starts and write access is available. Read access to the consistent data remains available.

To stop active-active relationships:

- **-access** is specified
- The relationship's state is `consistent_copying`
- The relationship's status is `primary_offline`

Specify `stoprelationship -access` to obtain host read or write access to a volume in an active-active relationship that contains an older but consistent image that might be needed in a disaster recovery scenario (the relationship has a `consistent_copying` state).

Any remote copy secondary volumes that are mapped to hosts of type `hide_secondary` are presented to the host if you specify **-access**. Paths to those volumes appear to the host, and a logical unit number (LUN) inventory changed unit attention is raised to report their availability.

When you enable read or write access for a `consistent_copying` relationship, specify `stoprelationship -access` to restore a consistent image on the secondary change volume that is using a FlashCopy mapping. (Depending on how long this operation lasts the CLI command might delay.) This process fails if either the secondary volume or secondary change volume are offline. If you stop the relationship without specifying the **-access** parameter, the relationship becomes `consistent_stopped` and the secondary change volume is unchanged.

To enable access to a secondary volume that is not consistent, specify `rmrelationship -force`.

Table 112. stoprelationship consistency group states		
Initial state	Final state	Notes
<code>inconsistent_stopped</code>	<code>inconsistent_stopped</code>	If access is specified, the command is rejected.
<code>inconsistent_copying</code>	<code>inconsistent_stopped</code>	If access is specified, the command is rejected with no effect and the relationship remains in the <code>inconsistent_copying</code> state.
<code>consistent_stopped</code>	<code>consistent_stopped</code>	If access is specified, the final state is <code>idling</code> .
<code>consistent_synchronized</code>	<code>consistent_stopped</code>	If access is specified, the final state is <code>idling</code> . If access is not specified, the final state is <code>consistent_stopped</code> .
<code>consistent_copying</code>	<code>consistent_stopped</code>	If access is specified, the final state is <code>idling</code> . If access is not specified, the final state is <code>consistent_stopped</code> .
<code>idling</code>	<code>idling</code>	Remains in <code>idling</code> state whether access is specified or not.

Table 112. **stopcrrelationship** consistency group states (continued)

Initial state	Final state	Notes
idling_disconnected	unchanged	If specified without access , the relationship or group remains in <code>idling_disconnected</code> state. If the clustered systems reconnect, the relationship or group is in either <code>inconsistent_stopped</code> or <code>consistent_stopped</code> state.
inconsistent_disconnected	inconsistent_stopped	The command is rejected, with or without the access flag.
consistent_disconnected	consistent_stopped	The command is rejected if specified without access . If specified with access , the relationship or group moves to <code>idling_disconnected</code> state.

An invocation example

```
stopcrrelationship rccopy1
```

The resulting output:

```
No feedback

startrcrelationship

Use the **startrcrelationship** command to start the Metro Mirror or Global Mirror relationship copy process, set the direction of copy if undefined, and (optionally) mark the secondary volume of the relationship as clean. The relationship must be a stand-alone relationship. You can also use this command to restart the active-active relationship copy process after you specify **stoprcrelationship -access**.

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

switchrcconsistgrp

Use the **switchrcconsistgrp** command to reverse the roles of the primary and secondary volumes in a Metro Mirror or Global Mirror consistency group when that consistency group is in a consistent state. All the relationships in the consistency group are affected by this change.

Syntax

```
➔ switchrcconsistgrp — -primary — master — rc_consist_group_id — ➔
                        aux      rc_consist_group_name
```

Parameters

-primary master | aux

(Required) Specifies whether the master or auxiliary side of the relationships in the group become the primary volumes.

rc_consist_group_id | rc_consist_group_name

(Required) Specifies the ID or name of the consistency group to switch.

Description

This command applies to a consistency group. It is normally issued to reverse the roles of the primary and secondary volumes in a consistency group, perhaps as part of a failover process that is associated with a disaster recovery event.

Note: You cannot switch a consistency group if the primary and secondary volumes are different sizes.

Write access to the former primary volumes is lost and write access to the new primary volumes is acquired.

This command is successful when the consistency group is in a connected, consistent state, and when you reverse the direction of the relationships would not lead to a loss of consistency, for example, when the consistency group is consistent and synchronized. The consistency group must be in one of the following states in order for the **switchrcconsistgrp** command to process correctly:

- ConsistentSynchronized
- ConsistentStopped and Synchronized
- Idling and Synchronized

Note: This command is rejected under any of the following conditions:

- You switch consistency group relationship so that the new secondary becomes the target volume of an active FlashCopy mapping.
- Any of the indicated secondary volumes (in the consistency group) are the target of an existing FlashCopy mapping.
- Using Global Mirroring with the multi cycling mode

The consistency group moves to the ConsistentSynchronized state after the successful completion of this command. If you specify the **-primary** parameter and it is the same as the current primary, the command has no effect.

When the direction of the consistency group is changed, a volume that is a secondary volume in a remote copy relationship becomes a primary volume. In addition, a primary volume that is in a remote copy relationship becomes a secondary volume. If the resultant secondary volume is mapped to a host of type `hide_secondary`, it is no longer presented to that host. However, the mapping still exists for configuration purposes. If the volume that was a secondary volume before the switch is mapped to a host of type `hide_secondary`, it is presented to that host because it is no longer a secondary volume.

You cannot switch directions for an active-active consistency group.

An invocation example

```
switchcrconsistgrp -primary aux rccopy2
```

The resulting output:

```
No feedback
```

stoprcconsistgrp

Use the **stoprcconsistgrp** command to stop the copy process for a Metro Mirror, Global Mirror, or active-active consistency group. This command can also be used to enable write access to the secondary volumes in the group if the group is in a consistent state.

stoprcrelationship

Use the **stoprcrelationship** command to stop the copy process for a Metro Mirror or Global Mirror stand-alone relationship. You can also use this command to enable write access to a consistent secondary volume that includes for an active-active relationship.

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

switchrcrelationship

Use the **switchrcrelationship** command to reverse the roles of primary and secondary volumes in a stand-alone Metro Mirror or Global Mirror relationship when that relationship is in a consistent state.

Syntax

```
➤ switchrcrelationship — -primary master rc_rel_id  
                        aux rc_rel_name
```

Parameters

-primary master | aux

(Required) Specifies whether the master disk or the auxiliary disk is to be the primary.

rc_rel_id / rc_rel_name

(Required) Specifies the ID or the name of the relationship to switch.

Description

The **switchrcrelationship** command applies to a stand-alone relationship. It is rejected if it is used to try to switch a relationship that is part of a consistency group. It is normally issued to reverse the roles of the primary and secondary volume in a relationship perhaps as part of a failover process during a disaster recovery event.

Note: You cannot switch a relationship if the primary and secondary volumes are different sizes.

Write access to the old primary disk is lost. Write access to the new primary disk is acquired.

This command is successful when the relationship is in a connected, consistent state and when the direction of the relationship is reversed and it does not lead to a loss of consistency. This means that the relationship is consistent and synchronized. The relationship must be in one of the following states in order for the **switchrcrelationship** command to process correctly:

- ConsistentSynchronized
- ConsistentStopped and Synchronized
- Idling and Synchronized

Note: A command in idling state is rejected if any of the indicated secondary volumes is the target of an existing FlashCopy map.

The relationship moves to the **ConsistentSynchronized** state after the successful completion of this command. If you specify the **-primary** parameter with the current primary, the command has no effect.

When the direction of the relationship is changed, a volume that is a secondary volume in a remote copy relationship becomes a primary volume, and a primary volume in a remote copy relationship becomes a secondary volume. If the resultant secondary volume is mapped to a host (type `hide_secondary`), it is no longer presented to that host. However, the mapping still exists for configuration purposes. If the volume that was a secondary volume before the switch is mapped to a host of type `hide_secondary`, it is presented to that host because it is no longer a secondary volume.

The **switchrcrelationship** command is rejected if you use Global Mirroring with the **multi** cycling mode.

You cannot switch directions for an active-active relationship.

An invocation example

```
switchcrrrelationship -primary master rccopy2
```

The resulting output:

```
No feedback
```

Chapter 21. Migration commands

Use the migration commands to work with migration options for the system .

lsmigrate

Use the **lsmigrate** command to display the progress of all current data migration operations.

Syntax

➤ **lsmigrate** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

If you use multiple threads to migrate data, the progress increases when all threads complete the migration of an extent. For large extent sizes with many threads, which can result in large increments in the percentage progress.

Description

This command displays information of all the migrations that are currently in progress.

Note: Only user-initiated migrations are reported by using this command. Easy Tier migrations are not included in the output.

An invocation example

```
lsmigrate -delim :
```

The resulting output:

```
migrate_type:MDisk_Group_Migration
progress:96
migrate_source_vdisk_index:33
migrate_target_mdisk_grp:4
max_thread_count:4
migrate_source_vdisk_copy_id:1
```

Use the **migratevdisk** command to migrate an entire volume from one storage pool to another storage pool.

migrateexts

Use the **migrateexts** command to migrate extents from one managed disk to another.

Syntax

```
➔ migrateexts  — -source — source_mdisk_id — -target →
                        |
                        | source_mdisk_name
                        |
➔ — target_mdisk_id — -exts — number_of_extents →
    |
    | target_mdisk_name
    |
➔ — -threads — number_of_threads — -copy — id — -vdisk →
    |
    | vdisk_id
    |
    | vdisk_name
    |
```

Parameters

-source source_mdisk_id / source_mdisk_name

(Required) Specifies the MDisk on which the extents currently reside.

-target target_mdisk_id / target_mdisk_name

(Required) Specifies the MDisk to migrate the extents to.

-exts number_of_extents

(Required) Specifies the number of extents to migrate.

-threads number_of_threads

(Optional) Specifies the number of threads to use while migrating these extents. You can specify 1 - 4 threads. The default number of threads is 4.

-copy id

(Required if the specified volume has more than one copy) Specifies the volume copy that the extents belong to.

-vdisk vdisk_id / vdisk_name

(Required) Specifies the volume that the extents belong to.

Description

This command migrates a given number of extents from the source volume and the managed disk that contains extents that are used to make up the volume. The target is a managed disk within the same storage pool.

You cannot specify this command for thin-provisioned or compressed volume copies that are in data reduction storage pools.

If a large number of extents are being migrated, you can specify 1 - 4 threads. You can issue the **lsmigrate** command to check the progress of the migration.

The **migrateexts** command fails if there are insufficient free extents on the target managed disk. To avoid this problem, do not issue new commands that use extents until the extents migration is completed.

The **migrateexts** command fails if the target or source volume is offline, or if Easy Tier is active for the volume copy. Correct the offline condition before attempting to migrate the volume.

Note: Migration activity on a single managed disk is limited to a maximum of 4 concurrent operations. This limit does not take into account whether the managed disk is the source or the destination target. If more than four migrations are scheduled for a particular managed disk, further migration operations are queued pending the completion of one of the currently running migrations. If a migration operation is stopped for any reason, a queued migration task can be started. However, if a migration is suspended, the current migration continues to use resources and a pending migration is not started. For example, the following setup is a possible initial configuration:

- MDiskGrp 1 has volume 1 created in it
- MDiskGrp 2 has volume 2 created in it
- MDiskGrp 3 has only one MDisk

With the previous configuration, the following migration operations are started:

- Migration 1 migrates volume 1 from MDiskGrp 1 to MDiskGrp 3, running with 4 threads.
- Migration 2 migrates volume 2 from MDiskGrp 2 to MDiskGrp 3, running with 4 threads.

Due to the previous limitations, the two migration operations do not always run at the same speed. MDiskGrp 3 has only one MDisk and the two migration operations have a total of 8 threads that are trying to access the one MDisk. Four threads are active. The remaining threads are in standby mode waiting to access the MDisk.

Remember: This command cannot be used if the source MDisk is a SAS MDisk (which works in image mode only).

An invocation example

```
migrateexts -vdisk vdisk4 -source mdisk4 -exts
64 -target mdisk6 -threads 4
```

The resulting output:

```
No feedback
```

[migratetoimage](#)

Use the **migratetoimage** command to migrate data from a volume (image mode or managed mode) onto a new image mode volume copy. The target disk does not have to be in the same storage pool as the source disk.

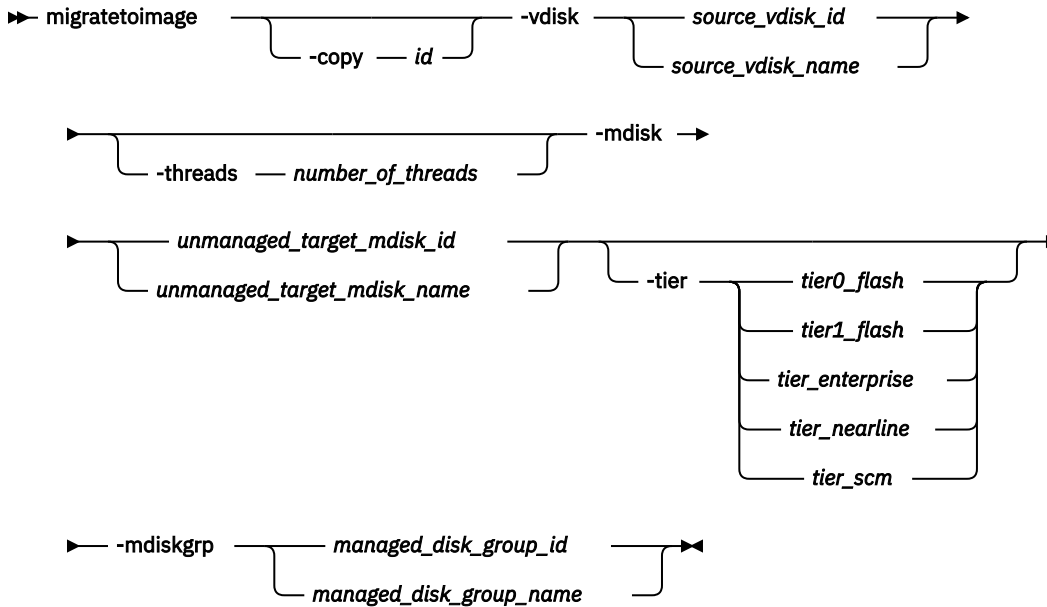

[migratevdisk](#)

Use the **migratevdisk** command to migrate an entire volume from one storage pool to another storage pool.

migratetoimage

Use the **migratetoimage** command to migrate data from a volume (image mode or managed mode) onto a new image mode volume copy. The target disk does not have to be in the same storage pool as the source disk.

Syntax

Parameters

-vdisk source_vdisk_id | name

(Required) Specifies the name or ID of the source volume to be migrated.

-copy id

(Required if the specified volume has more than one copy) Specifies the volume copy to migrate from.

-threads number_of_threads

(Optional) Specifies the number of threads to use during the migration of extents. You can specify 1 - 4 threads. The default number of threads is 4.

-mdisk unmanaged_target_mdisk_id | name

(Required) Specifies the name of the MDisk to which the data must be migrated. This disk must be unmanaged and large enough to contain the data of the disk that is being migrated.

-mdiskgrp managed_disk_group_id | name

(Required) Specifies the storage pool into which the MDisk must be placed, after the migration has completed.

-tier tier0_flash | tier1_flash | tier_enterprise | tier_nearline | tier_scm

(Optional) Specifies the tier of the MDisk being added.

tier0_flash

Specifies a **tier0_flash** hard disk drive or an external MDisk for the newly discovered or external volume.

tier1_flash

Specifies an **tier1_flash** (or flash drive) hard disk drive or an external MDisk for the newly discovered or external volume.

tier_enterprise

Specifies a `tier_enterprise` hard disk drive or an external MDisk for the newly discovered or external volume.

tier_nearline

Specifies a `tier_nearline` hard disk drive or an external MDisk for the newly discovered or external volume.

tier_scm

Specifies a `tier_scm` hard disk drive or an external MDisk for the newly discovered or external volume.

Description

This command cannot be used to if the source volume copy is in a child pool or if the MDisk group that is specified is a child pool. This command does not work if the volume is fast formatting.

Note: You cannot migrate a volume or volume image between storage pools if cloud snapshot is enabled on the volume.

The **migratetoimage** command migrates the data of a user-specified volume by consolidating its extents (which might reside on one or more MDisk) onto the extents of the target MDisk that you specify. After migration is complete, the volume is classified as an image type volume, and the corresponding mdisk is classified as an image mode MDisk.

The managed disk that is specified as the target must be in an unmanaged state at the time that the command is run. Running this command results in the inclusion of the MDisk into the user-specified storage pool.

You cannot specify **migratetoimage** if the target or source volume is offline. Correct the offline condition before you migrate the volume.

Remember: This command cannot be used on a volume that is owned by a filesystem or if the source MDisk is an SAS MDisk (which works in image mode only).

If the volume (or volume copy) is a target of a FlashCopy mapping with a source volume in an active-active relationship the new storage pool must be in the same site as the source volume. If the volume is in an active-active relationship the new storage pool must be located in the same site as the source volume. Additionally, the site information for the MDisk being added must be well-defined and match the site information for other MDisk in the storage pool.

Note: You cannot migrate data from a volume if the target volume's formatting attribute value is yes.

You cannot specify **migratetoimage** to migrate a thin or compressed volume in a data reduction storage pool to an image mode volume. You must replicate the volume to a [standard-provisioned](#), thin, or compressed volume copy in a standard storage pool before you migrate a thin or compressed volume that is in a data reduction pool from one clustered system to another clustered system.

An encryption key cannot be used when migrating an image mode MDisk. To use encryption (when the MDisk has an encryption key), the MDisk must be self-encrypting.

An invocation example

The following example specifies that the user wants to migrate the data from `vdisk0` onto `mdisk5` and that the MDisk must be put into the storage pool `mdgrp2`.

```
migratetoimage -vdisk vdisk0 -mdisk mdisk5 -mdiskgrp mdgrp2 -tier tier_nearline
```

The resulting output:

```
No feedback
```

Related reference

[ismigrate](#)

Use the **lsmigrate** command to display the progress of all current data migration operations.

migrateexts

Use the **migrateexts** command to migrate extents from one managed disk to another.

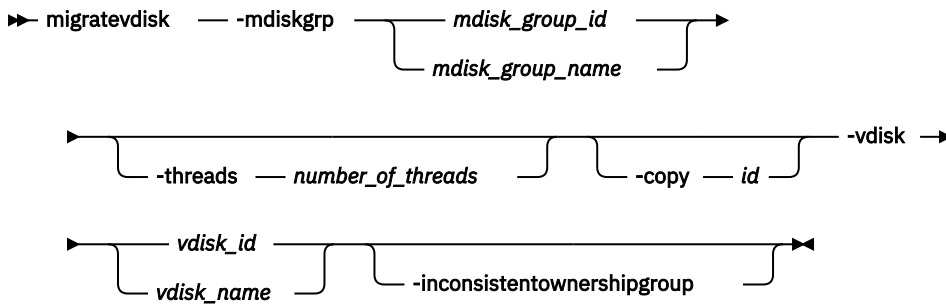

migratevdisk

Use the **migratevdisk** command to migrate an entire volume from one storage pool to another storage pool.

migratevdisk

Use the **migratevdisk** command to migrate an entire volume from one storage pool to another storage pool.

Syntax

Parameters

-mdiskgrp mdisk_group_id / mdisk_group_name

(Required) Specifies the new storage pool ID or name.

-threads number_of_threads

(Optional) Specifies the number of threads to use during the migration of these extents. You can specify 1 - 4 threads. The default number of threads is 4.

-copy id

(Required if the specified volume has more than one copy) Specifies the volume copy to migrate.

-vdisk vdisk_id / vdisk_name

(Required) Specifies the volume ID or name to migrate in to a new storage pool.

-inconsistentownershipgroup

(Optional) If specified, this flag allows the object to be in inconsistent ownership.

Description

The **migratevdisk** command migrates the specified volume into a new storage pool; all the extents that make up the volume are migrated onto free extents in the new storage pool.

You can reassign a volume from a:

- Child pool to its parent pool
- Parent pool to one of its child pools
- Between the child pools in the same parent pool
- Between two parent pools

Note: You cannot migrate a volume between storage pools if cloud snapshot is enabled on the volume.

You can issue the **lsmigrate** command to view the progress of the migration.

The process can be prioritized by specifying the number of threads to use during the migration. Using only one thread puts the least background load on the system.

The **migratevdisk** command fails if there are insufficient free extents on the targeted storage pool for the duration of the command. To avoid this problem, do not issue new commands that use extents until the volume migration is completed.

The **migratevdisk** command fails if the target volume or source volume is offline. Correct the offline condition before you attempt to migrate the volume.

Remember: You cannot specify this command:

- If the source MDisk is a SAS MDisk (which works in image mode only).
- If the volume that is being migrated is thin-provisioned or compressed and in a data reduction pool.
- If the target pool is a data reduction pool and the volume that is being migrated is either thin-provisioned or compressed.

For these volume types, you must create a volume copy in the destination pool by using volume mirroring to perform the migration. For more information, see the **addvdiskcopy** or **addvolume** command.

If the volume (or volume copy) is a target of a FlashCopy mapping with a source volume in an active-active, relationship the new storage pool must be in the same site as the source volume. If the volume is in an active-active relationship, the new storage pool must be located in the same site as the source volume.

When the volume is being migrated from a parent pool to another parent pool, the information is moved (unchanged), whether or not one or other is encrypted. The parent pool and the child pool cannot have an encryption key (or else the child pool would have failed during creation).

- A parent pool to parent pool migration is allowed in all cases.
- A parent pool to child pool migration is not allowed if child has encryption key.
- A child pool to parent pool or child pool is not allowed if either child pool has an encryption key.

An invocation example

```
migratevdisk -vdisk 4 -mdiskgrp Group0 -threads 2
```

The resulting output:

```
No feedback
```

An invocation example

This example requires the *-inconsistentownershipgroup* flag if the new mdiskgrp (mydiskgrp) is in a different ownership group from the one where the volume is located. It means that any move from an owned mdiskgrp to the parent mdiskgrp causes an inconsistency since parents cannot be owned.

```
migratevdisk -mdiskgrp mydiskgrp -inconsistentownershipgroup -vdisk myvdisk
```

The resulting output:

```
No feedback
```

Chapter 22. Service information commands

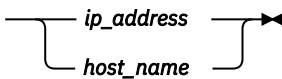

Use the service information commands to view hardware status and to report hardware errors.

Note: You can find out the *panel_name* for each of your nodes by issuing `sainfo lsservicenodes`.

sainfo host

Use the **host** command to change an Internet Protocol (IP) address to a host name or change a host name to an IP address.

Syntax

➔ `sainfo host` — `-ip_or_name`  `ip_address` / `host_name`

Parameters

-ip_or_name *ip_address* / *host_name*

(Required) Specifies the host system IP address or host system name. The value for the IP address must be a standard IPv4 or IPv6 address. The value for the host name must be an alphanumeric string.

Description

This command changes an IP address to a host name or change a host name to an IP address.

This command handles Domain Name System (DNS) lookup and assists with DNS configuration.

Use this command to convert host names to IP addresses or IP address to host names.

An invocation example

```
sainfo host -ip_or_name varyd
```

The resulting output:

```
Host varyd not found: 3(NXDOMAIN)
```

An invocation example

```
sainfo host -ip_or_name compass.ssd.hursley.ibm.com
```

The resulting output:

```
compass.ssd.hursley.ibm.com has address 9.71.44.59
```

sainfo lsbootdrive

Use the **lsbootdrive** command to return the drive information of the internal boot drives for the specified node. This command applies to SAN Volume Controller 2145-DH8 systems.

Syntax

►► **sainfo lsbootdrive** — *panel_name* ►►

Parameters

panel_name

(Optional) Identifies the node that is being used.

Description

The command displays information about internal boot drives for the specified node (if applicable).

This table provides the possible values for attributes that are displayed as data in the output views.

Table 113. lsbootdrive attribute values	
Attribute	Value
panel_id	Identifies the panel ID of the node that contains the boot drive. The value is a 7-character alphanumeric string.
node_id	Identifies the ID (in decimal format) of the node that contains the boot drive.
node_name	Identifies the name of the node that contains the boot drive.

Table 113. **lsbootdrive** attribute values (continued)

Attribute	Value
can_sync	Indicates when synchronization is needed and is not prevented by another problem. The values are yes or no. Remember: This value must be yes when status is out_of_sync. If the status is not out_of_sync the value is no.
slot_id	Identifies the ID (in decimal format) of the slot within the node.
booted	Indicates whether the node started from the specified drive. The values are yes, no.
status	Indicates the slot status. The values are: <ul style="list-style-type: none"> • missing indicates that the slot must be occupied, but the software cannot detect a drive. It also indicates the serial number of the expected drive. • empty indicates that the slot is supposed to be empty and is empty. • unsupported indicates that the slot is supposed to be empty but is not. • failed indicates that the drive in the slot is not working. • uninitialized indicates that the drive is not formatted for the system. • wrong_node indicates that the drive is working but is not in the correct node. It also indicates the serial number of the node the drive must be in and might indicate the serial number of the drive that must be in the slot. • wrong_slot indicates that the drive is working correctly - it is in the right node but the wrong slot. It also indicates which drives belong in which slots. • out_of_sync indicates that the drive is working correctly but must be resynchronized. Make sure the value of can_sync is yes before you specify the command <code>chbootdrive -sync</code>. • online indicates that the drive in the slot is working correctly. • unknown indicates that the node is not an active member of the system, and the state of the drive in that slot is unknown.
actual_drive_sn	Indicates the serial number of the drive in the slot. The value is an alphanumeric string or blank if no drive is in the slot.
configured_drive_sn	Identifies the serial number of the drive that must be in the slot. The value is an alphanumeric string or blank if no drive is in the slot.
actual_node_sn	Indicates the serial number of the node the drive (currently in the slot) belongs in. The value is an alphanumeric string or blank if no drive is in the slot.
identify	Indicates whether <code>chnodebootdrive -identify</code> is specified. The following values are possible for this attribute: <ul style="list-style-type: none"> • on indicates <code>chnodebootdrive -identify yes -slot</code> is specified • off indicates <code>chnodebootdrive -identify no -slot</code> is specified • N/A indicates that the drive slot cannot be identified.
FRU_part_number	Identifies the field-replaceable unit (FRU) part number of the drive. The value is a 7-character alphanumeric string or blank if no drive exists. The value is N/A if the drive is not supplied for your system.

Table 113. **lsbootdrive** attribute values (continued)

Attribute	Value
FRU_identity	Identifies the 11S number that combines the manufacturing part number and serial number. The value is a 22-character alphanumeric string. The value is N/A if the drive is not supplied for your system.

Note: If the status is `out_of_sync` and `can_sync` is set to `no`, look for an indication to determine what must be fixed to make resynchronization possible.

An invocation example

```
sainfo lsbootdrive
```

The following output is displayed:

panel_id	node_id	node_name	can_sync	slot_id	booted	status	actual_drive_sn	configured_drive_sn	actual_node_sn	identify	FRU_part_number	FRU_identity
bfbfbf1	1	bfn1	no	1	yes	online	1234567	1234567	bfbfbf1	off	90Y8878	
bfbfbf1	1	bfn1	no	2	no	missing		1234568		off		
bfbfbf1	1	bfn1	no	3		empty						
bfbfbf1	1	bfn1	no	4		empty						
bfbfbf1	1	bfn1	no	5		empty						
bfbfbf1	1	bfn1	no	6		empty						
bfbfbf1	1	bfn1	no	7		empty						
bfbfbf1	1	bfn1	no	8	no	unsupported	12B0345

Use the **traceroute** command to print wide area network (WAN) route packets to a specified host.

sainfo lscmdstatus

Use the **lscmdstatus** command to display the status of any currently running service-aid task.

Syntax

➤ sainfo — lscmdstatus  *panel_name*

Parameters

panel_name

The name of the panel. This command fails if the *panel_name* ID is not in the list that is returned by **lsservicenodes**.

Note: If *panel_name* is not supplied, this value applies to the node on which the command is running.

Description

This command displays the status of any currently running service-aid task. If no task is running, then the completion status of the last task is displayed. Any user can specify this CLI command.

If no service-aid tasks run since the node was last restarted, the command returns immediately with no output. Otherwise, it display something similar to example below.

This table provides the attribute values that can be displayed as output view data.

Table 114. lscmdstatus output	
Attribute	Description
T3_status	Indicates the T3 recovery status.
T3_status_data	Indicates the T3 recovery status activity.
cpfiles_status	Indicates the cpfiles command status.
cpfiles_status_data	Indicates the cpfiles command activity.
snap_status	Indicates the snap command status.
installsoftware_status	Indicates the installsoftware command status.
supportupload_status	Indicates the upload activity status. The values are: <ul style="list-style-type: none">• active indicates that the upload is ongoing.• complete indicates that the upload completed successfully.• failed indicates that the upload failed.• abort indicates that the upload is aborted.• wait indicates that the upload is underway but not completed.
supportupload_status_data	Indicates upload activity information (for example uploading).
supportupload_progress_percent	Indicates the upload progress percentage. The value is a number in the range 0 - 100.
supportupload_throughout_KBps	Indicates the upload speed in kilobytes per second (KBps). The value is a number (integer).

Table 114. **lscmdstatus** output (continued)

Attribute	Description
supportupload_filename	Indicates the file name. The standard length is 256 characters.
downloadsoftware_status	Indicates the download activity status. The values are: <ul style="list-style-type: none"> • active indicates that the download is ongoing. • complete indicates that the download completed successfully. • failed indicates that the download failed. • abort indicates that the download is aborted. • .
downloadsoftware_status_data	Indicates the download activity information (for example Downloading the bundle).
downloadsoftware_progress_percent	Indicates the download progress percentage. The value is a number in the range 0 - 100.
downloadsoftware_throughput_KBps	Indicates the download speed in kilobytes per second (KBps). The value is a number (integer).
downloadsoftware_size	Indicates the total size of the selected bundle to download. The value must be a number (decimal) and must be in the format TiB, GiB, MiB, or KiB.

An invocation example

```
sainfo lscmdstatus
```

The resulting output:

```
last_command satask cpfiles -prefix /dumps/test_cpf* -source 111825
last_command_status CMMVC8044I Command completed successfully.

sainfo traceroute

Use the **traceroute** command to print wide area network (WAN) route packets to a specified host.

sainfo lshardware

Use the **lshardware** command to view the configured and actual hardware configuration of a node in the system.

Syntax

➤ sainfo — lshardware — *-delim* — *delimiter* — *panel_name* ➤

Parameters

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

panel_name

(Optional) The node panel name.

Note: If **panel_name** is not supplied, this parameter applies to the node on which the command is running.

Description

When the node is in a service state, use this command to view the current hardware configuration. This table provides the possible values that are applicable to the attributes that are displayed as data in the output views.

Table 115. lshardware attribute values	
Attribute	Value
panel_name	Indicates the node panel name.
node_id	Indicates the node unique ID. The value is a number or blank if not in a system.

Table 115. **lshardware** attribute values (continued)

Attribute	Value
node_name	Indicates the node name. The value is an alphanumeric string or blank if not in a system.
node_status	Indicates the node status.
hardware	Indicates the hardware model, such as DH8.
actual_different	Indicates whether the node hardware is different than the configured hardware.
actual_valid	Indicates whether the node hardware is valid.
memory_configured	Indicates the configured amount of memory (in GB).
memory_actual	Indicates the currently installed amount of memory (in GB).
memory_valid	Indicates whether the actual memory is a valid configuration.
cpu_count	Indicates the maximum number of CPUs for the node.
cpu_socket	Indicates the ID of socket to which the CPU fields refer.
cpu_configured	Indicates the configured CPU for this socket.
cpu_actual	Indicates the currently installed CPU in this socket.
cpu_valid	Indicates whether the currently installed CPU is a valid configuration.
adapter_count	Indicates the maximum number of adapters for the node (differs by node type).
adapter_location	Indicates the location of this adapter.
adapter_configured	Indicates the configured adapter for this location.
adapter_actual	Indicates the currently installed adapter for this location.
adapter_valid	Indicates whether the adapter in this location is valid.
ports_different	Indicates whether adapter ports can support more functions.

Use the **sainfo lsnodeip** command to list the node IP addresses of Ethernet ports on the node.

[sainfo lsnodeipconnectivity](#)

Use the **sainfo lsnodeipconnectivity** command to list the port level iSER (iSCSI Extensions for RDMA) clustering session connectivity information.

sainfo lsservicenodes

Use the **lsservicenodes** command to display a list of all the nodes that can be serviced by using the service assistant CLI.

sainfo lsservicerecommendation

Use the **lsservicerecommendation** command to determine what actions must be completed when you service a node.

sainfo lsservicestatus

Use the **lsservicestatus** command to display the status of a node.

sainfo traceroute

Use the **traceroute** command to print wide area network (WAN) route packets to a specified host.

sainfo lsnodediscoverysubnet

Use the **lsnodediscoverysubnet** command to list the IPv4 subnets that are used for local node discovery. This command is available only on cloud systems.

Syntax

➔ **sainfo lsnodediscoverysubnet** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This command returns a list of the 32-bit subnet nodes that used for local node discovery. Note: IPv6 is not supported. This table provides the possible output values.

Table 116. lsnodediscoverysubnet attribute values	
Attribute	Value
id	Displays the position of the subnet set in the subnet table.
subnet	Displays the subnet (32 bits) on which the target node is located.

An invocation example

```
lsnodediscoverysubnet
```

The resulting output:

id	subnet
1	172.25.0.0/28
2	172.26.0.0/28
3	10.25.0.0/28

sainfo lsnodeip

Use the **sainfo lsnodeip** command to list the node IP addresses of Ethernet ports on the node.

Syntax

➤ **sainfo lsnodeip** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data is available to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

panel_name

(Optional) Specifies the system or node on which the command is invoked. The value must be an alphanumeric.

Description

This command lists the node IP addresses for Ethernet ports on a node.

This table provides the attribute values that can be displayed as output view data.

<i>Table 117. sainfo lsnodeip output</i>	
Attribute	Description
port_id	Indicates the Ethernet port ID on the node. The value must be a number (decimal or integer). For more information, see the lsservicestatus command.
rdma_type	Indicates the RDMA Capabilities of the port. The values are colon-separated (Example: RoCE : iWARP).
port_speed	Indicates the speed of the port in Gbps.
vlan	Indicates the Virtual LAN identifier of the port.
link_state	Indicates whether the port is active or inactive.
state	Indicates whether an IP Address for clustering purposes is assigned to the Ethernet Port. The possible values are configured or unconfigured (default).
node_IP_address	Indicates the Internet Protocol Version 4 (IPv4) node IP address.
subnet_mask	Indicates the IPv4 subnet mask value.
gateway	Indicates the IPv4 gateway address.

An invocation example

```
sainfo lsnodeip
```

The following output is displayed:

```

port_id  rdma_type  port_speed  vlan    link_state  state        node_IP_address
subnet_mask gateway
1        1Gb/s      1Gb/s      inactive  unconfigured
2        1Gb/s      1Gb/s      inactive  unconfigured
3        RoCE       25Gb/s     103      active      configured   192.168.54.101
255.255.255.0 192.168.54.1
4        RoCE       25Gb/s     active    configured   192.168.54.102
255.255.255.0 192.168.54.1
... for all the ethernet ports in the system
```

sainfo lsnodeipconnectivity

Use the **sainfo lsnodeipconnectivity** command to list the port level iSER (iSCSI Extensions for RDMA) clustering session connectivity information.

Syntax

► **sainfo lsnodeipconnectivity** 

Parameters

panel_name

(Optional) Specifies the system or node on which the command is invoked. The value must be an alphanumeric string.

Description

This command lists the port level connectivity information for node to node or clustering connectivity.

This table provides the attribute values that can be displayed as output view data.

Table 118. **sainfo lsnodeipconnectivity** output

Attribute	Description
status	Indicates the status of the connection attempt for the port level connectivity for node to node or clustering. A value of Discovered indicates that ports are configured, but the connection could not be established. The reason for the connection issue is described in the error_data field. A value of Connected:protocol indicates a successful connection.
local_port_id	Indicates the local port identifier for the node Ethernet port number that is displayed in the lsservicestatus output.
local_vlan	Indicates the local port Virtual LAN Identifier for the node Ethernet port number that is displayed in the lsservicestatus output.
local_rdma_type	Indicates the local port RDMA type.
local_ip_addr	Indicates the local IP address.
remote_port_id	Indicates the peer or target port identifier for the node Ethernet port number that is displayed in the lsservicestatus output.
remote_vlan	Indicates the remote port Virtual LAN Identifier for the node Ethernet port number that is displayed in the lsservicestatus output.
remote_rdma_type	Indicates the remote port RDMA type.
remote_ip_addr	Indicates the remote IP address.
remote_wwnn	Indicates the remote World Wide Node Name (WWNN).
remote_panel_name	Indicates the remote node unique panel name.
cluster_id	Indicates the Cluster ID of the peer system.
error_data	Displays information that details any problems with the connection.

The following table lists the values for the **error_data** field and possible corrective actions.

Table 119. **sainfo lsnodeipconnectivity error_data**

error_data value	Description	Possible Corrective Action
Protocol mismatch	Source port RDMA adapter and destination Port RDMA adapter are not compatible with each other.	Make sure that both of the RDMA adapters are the same type (Ex: RoCE to RoCE, iWARP to iWARP).
Unreachable	The source IP address and destination IP address are not reachable.	Make sure that both of the IPs are reachable. You can use the <code>satask ping</code> command to check the network connectivity of the local and remote ports.
Duplicate IP	A duplicate IP address is set.	Make sure that the IP addresses that are set are unique on the same network.
Degraded	Negotiated speed does not match. Degraded is set when a slower speed is selected than the adapter supported maximum speed.	Make sure that the switch adapters on both nodes support the maximum speed.
VLAN ID Mismatch	The local and remote port Virtual LAN Identifiers do not match.	For the clustering link to get created, make sure that the VLAN IDs match.

An invocation example

```
sainfo lsnodeipconnectivity
```

The following output is displayed:

status	local_port_id	local_vlan	local_rdma_type	local_ip_addr	remote_port_id	remote_vlan	remote_rdma_type	remote_ip_addr	remote_wwnn	remote_panel_name	cluster_id

sainfo lsservicenodes

Use the **lsservicenodes** command to display a list of all the nodes that can be serviced by using the service assistant CLI.

Syntax

➤ sainfo — lsservicenodes ➤

Parameters

None

Description

Nodes that are `online_spare` display as active nodes. No spare node extra fields are left blank.

This command displays a list of all the nodes that can be serviced by using the service assistant CLI. This list includes nodes that at a code level of at least 6.2.0, are visible on the fabric, and meet one of the following conditions:

- The partner node in a control enclosure to the node that is running the command.
- In the same clustered system as the node that is running the command.
- In candidate state.
- Not in a clustered system and in service state.
- Not in an enclosure with a stored clustered system ID (which is not the clustered system ID of the local node).

Nodes that are not clustered with the local node are not shown unless they are the partner node. This table shows possible outputs.

Table 120. lsservicenodes outputs	
Attribute	Value
panel_name	Indicates the front panel name, enclosure IDs, or canister IDs that identify the node.
cluster_id	Indicates the system ID. The value is blank if node is a candidate; otherwise, the value is determined from <code>vpd_cluster</code> .
cluster_name	Indicates the system name. The value is blank if node is a candidate; otherwise, the value is determined from <code>vpd_cluster</code> .
node_id	Indicates the node ID. The value is blank if node is a candidate; otherwise, the value is determined from <code>vpd_cluster</code> .
node_name	Indicates the node name. The value is blank if node is a candidate; otherwise, the value is determined from <code>vpd_cluster</code> .
relation	Indicates the relationship. The values are: <ul style="list-style-type: none">• <code>local</code> indicates that the node the CLI command was issued from.• <code>partner</code> indicates that the node is in the same enclosure as the local node.• <code>cluster</code> indicates that nodes other than the partner that is in the same system as the local node.• <code>candidate</code> indicates that the node is not part of the system.

Table 120. **lsservicenodes** outputs (continued)

Attribute	Value
node_status	<p>Indicates the node status. The values are:</p> <ul style="list-style-type: none"> • active indicates that the node is part of a system and can perform I/O. • service indicates that the node is in service mode, standby mode, or node rescue mode. • candidate indicates that the node is not part of a system. • starting indicates that the node is part of a system and is attempting to join the system, and cannot perform I/O. • spare indicates that the node is a spare node.
error_data	Indicates the outstanding error and error data that is indicated by priority.

An invocation example

```
sainfo lsservicenodes
```

The resulting output:

panel_name	cluster_id	cluster_name	node_id	node_name	relation	node_status
error_data						
01-1	0000020073C0A0D4	Cluster_9.180.28.82	1	node1	local	Active
01-2	0000020073C0A0D4	Cluster_9.180.28.82	2	node2	partner	Active

Use the **lsservicestatus** command to display the status of a node.

[sainfo traceroute](#)

Use the **traceroute** command to print wide area network (WAN) route packets to a specified host.

sainfo lsservicerecommendation

Use the **lsservicerecommendation** command to determine what actions must be completed when you service a node.

Syntax

➤ sainfo — lsservicerecommendation 

Parameters

panel_name

(Optional) If no panel ID is provided, the service recommendation for the local node is returned. If a *panel_name* from the list that is returned by **lsservicenodes** is specified, then the service recommendation for that node is returned. The command fails if the *panel_name* is not in the list that is returned by **lsservicenodes**.

Note: If *panel_name* is not supplied, this applies to the node on which the command is running.

Description

This command determines what actions must be completed when you service a node.

An invocation example

Example for *service_action*:

```
sainfo lsservicerecommendation
```

The resulting output:

```
Use fabric tools to diagnose and correct Fibre Channel fabric problem.
```

An invocation example

Example for *service_action*:

```
sainfo lsservicerecommendation
```

The resulting output:

```
No service action required, use console to manage node.
```

sainfo traceroute

Use the **traceroute** command to print wide area network (WAN) route packets to a specified host.

sainfo lsservicestatus

Use the **lsservicestatus** command to display the status of a node.

Syntax

➤ **sainfo** — **lsservicestatus**  *panel_name*

Parameters

panel_name

(Optional) If a *panel_name* is not provided, the service recommendation for the local node is returned. If a *panel_name* from the list that is returned by **lsservicenodes** is specified, then the service recommendation for that node is returned. The command fails if the *panel_name* ID is not in the list that is returned by **lsservicenodes**. This output is returned as the node status on all Universal Serial Bus (USB) flash drive commands.

Note: For 2076 nodes, the *panel name* is the value of the enclosure ID and canister ID or the enclosure serial number and canister location.

Description

Use this command to display the status of a node. This command provides all the information that can be obtained by using the front panel of a system node.

Nodes that are in the *online_spare* state are displayed as active nodes. No spare node extra fields are left blank.

You can run this command on any node (even one that is not part of a system) to obtain the vital product data (VPD) and error status.

This table shows the possible outputs.

Table 121. <i>lsservicestatus</i> output	
Attribute	Value
panel_name	Indicates the front panel name, enclosure IDs, or canister IDs that identify the node.
console_ip	Indicates an Internet Protocol (IP) Version 4 or 6 address. Note: This field might be blank if the node is not present in a system.
has_nas_key	Indicates the has_nas_key field value. The values are yes or no. Note: This field might be blank if the node is not present in a system.
fc_io_ports	Indicates the number of configured Fibre Channel (FC) input/output (I/O) ports on the node. The value is a number. This field is repeated for each management address. This field might not apply to your system.
fc_io_port_id	Indicates the ID of the FC I/O port. The value is a number. This field is repeated for each management address. This field might not apply to your system.
fc_io_port_WWPN	Indicates the Worldwide port name (WWPN) of the FC I/O port. The value is 16 hexadecimal characters (lowercase). This field is repeated for each management address. This field might not apply to your system.
fc_io_port_switch_WWPN	Indicates the WWPN of the fabric port name. The value is 16 hexadecimal characters (lowercase) or all zeros if never active. This field is repeated for each management address. This field might not apply to your system.
fc_io_port_state	Indicates whether the port is working - active or inactive. This field is repeated for each management address. This field might not apply to your system.
fc_io_port_FCF_MAC	Indicates the FCF MAC address for active Ethernet. The value is blank for inactive or broken Ethernet, or N/A for FC type. This field is repeated for each management address. This field might not apply to your system.
fc_io_port_vlanid	Indicates the virtual local area network (VLAN) ID being used. The value is three hexadecimal digits for previously active or inactive Ethernet, blank for Ethernet that is never active, or N/A for FC type. This field is repeated for each management address. This field might not apply to your system.
fc_io_port_type	Indicates the type of the platform port for the FC I/O port. This field is repeated for each management address. This field might not apply to your system.
fc_io_port_type_port_id	Indicates the platform port type index of the platform port supplies the FC I/O port. Use both fc_io_port_type_port_id and fc_io_port_type to find the platform port. This field is repeated for each management address. This field might not apply to your system.
cluster_id	Indicates the ID of a clustered system.
cluster_name	Indicates the name of a system. When you use this parameter, the detailed view of the specific system is displayed and any value that you specified by the - filtervalue parameter is ignored. If you do not specify the <i>cluster_name</i> parameter, the concise view of all systems that match the filtering requirements that are specified by the - filtervalue parameter are displayed.
cluster_status	Indicates that the error code is the same as the one displayed on the front panel.
cluster_ip_count	Indicates the maximum number of management addresses you can configure.

Table 121. **lsservicestatus** output (continued)

Attribute	Value
cluster_ip_port	Indicates the system IP port. This field is repeated for each management address.
cluster_ip	Indicates the Internet Protocol Version 4 (IPv4) management IP address. This field is repeated for each management address.
cluster_gw	Indicates the IPv4 management IP gateway. This field is repeated for each management address.
cluster_mask	Indicates the IPv4 management IP mask. This field is repeated for each management address.
cluster_ip_6	Indicates the Internet Protocol Version 6 (IPv6) management IP address. This field is repeated for each management address.
cluster_gw_6	Indicates the IPv6 management IP gateway. This field is repeated for each management address.
cluster_prefix_6	Indicates the IPv6 management IP prefix. This field is repeated for each management address.
node_id	Indicates the ID of the node that is being configured. The value is a number.
node_name	Indicates the name of the node that is being configured.
node_status	Indicates the node status. The values are: <ul style="list-style-type: none"> • active indicates that the node is part of a system and can perform I/O. • service indicates that the node is in service mode, standby mode, or node rescue mode. • candidate indicates that the node is not part of a system. • starting indicates that the node is part of a system and is attempting to join the system. • spare indicates that the node is a spare node.
config_node	Indicates whether it is a configuration node. The values are yes or no.
hardware	Indicates the hardware type.
service_IP_address	Indicates the IPv4 service address for the node.
service_gateway	Indicates the IPv4 service gateway for the node.
service_subnet_mask	Indicates the IPv4 service mask for the node.
service_IP_address_6	Indicates the IPv6 service address for the node.
service_gateway_6	Indicates the IPv6 service gateway for the node.
service_prefix_6	Indicates the IPv6 service prefix for the node.
node_IP_address	Indicates the IPv4 management node IP address, which the system uses for node discovery and IP clustering.
node_gateway	Indicates the IPv4 management node IP gateway.
node_subnet_mask	Indicates the IPv4 management node IP mask.
node_code_version	Indicates the version of system code for the node.
node_code_build	Indicates the build string for code on the node.

Table 121. **lsservicestatus** output (continued)

Attribute	Value
cluster_sw_build	Indicates the CSM build that the system is running.
node_error_count	Indicates the number of node errors.
node_error_data	Indicates the type of node errors.
FC_port_count	Indicates the number of FC ports. This field is repeated for each management address.
FC_port_id	Indicates the port ID. This field is repeated for each management address.
port_status	Indicates the port status. This value must match the port on the front panel, enclosure, or canister.
port_speed	Indicates the port speed. This value must match the port speed on the front panel, enclosure, or canister.
port_WWPN	Indicates the worldwide port number of the port.
SFP_type	Indicates the SFP type. The values are long-wave or short-wave.
ethernet_port_count	Indicates the number of detected Ethernet ports.
ethernet_port_id	Indicates the ID of an Ethernet port.
port_status	Indicates the port status. The values are: <ul style="list-style-type: none"> • online • offline • not configured online offline not configured
port_speed	Indicates the port speed. The values are: <ul style="list-style-type: none"> • 10 Mbps • 100 Mbps • 1 Gbps • 10 Gbps • 25 Gbps • full • half
MAC	Indicates a single MAC address.
vnport_count	Indicates the number of VN ports that are created on top of each physical Fibre Channel over Ethernet (FCoE) port.
vnport_id	Indicates the VN port ID.
vnport_wwpn	Indicates the WWPN assigned to the VN port.
vnport_FCF_mac	Indicates the MAC address for the FCF to which the VN port is connected.
vnport_vlanid	Indicates the VLAN ID used by the VN port. The value is blank for FC ports.
product_mtm	Indicates the machine type and model.
product_serial	Indicates the node serial number.

Table 121. **lservicestatus** output (continued)

Attribute	Value
disk_WWNN_prefix	The most recently used WWNN prefix.
node_WWNN	Indicates the last active WWNN stored in the node; blank if no system data.
enclosure_WWNN_1	Indicates the first canister WWNN from the enclosure VPD.
enclosure_WWNN_2	Indicates the second canister WWNN from the enclosure VPD.
node_part_identity	Indicates the 11S string from the hardware VPD.
node_FRU_part	Indicates the node field-replaceable unit (FRU) part number, if stored in node VPD
enclosure_part_identity	Indicates the S11 data.
PSU_count	N/A
PSU_id	N/A
PSU_status	N/A
time_to_charge	Indicates the estimated time (in minutes) needed for 50% of the battery to be charged.
Battery_charging	Indicates the percentage of charge of the batteries.
Battery_count	Indicates the number of expected batteries (two).
Battery_id	Indicates the ID of the slot the battery is in.
Battery_status	Indicates that the status is missing, failed, charging, or active.
Battery_FRU_part	Indicates the FRU part number of the battery.
Battery_part_identity	Indicates the 11S FRU identity of the battery (includes the serial number).
Battery_fault_led	Indicates the fault light-emitting diode (LED) status.
Battery_charging_status	Indicates the battery charge status.
Battery_cycle_count	Indicates the number of charge or discharge cycles that are performed by the battery.
Battery_powered_on_hours	Indicates the number of hours the battery is in a powered node.
Battery_last_recondition	Indicates the system time stamp of the last successful gas gauge calibration.
Battery_midplane_FRU_part	Indicates the FRU part number of the battery midplane
Battery_midplane_part_identity	Indicates the 11S FRU identity of the battery midplane (which includes the serial number).
Battery_midplane_FW_version	Indicates the firmware version that is running on the battery midplane.
Battery_power_cable_FRU_part	Indicates the FRU part number of the battery power cable.

Table 121. **lservicestatus** output (continued)

Attribute	Value
Battery_power_sense_cable_FRU_part	Indicates the FRU part number of the battery midplane power sense cable.
Battery_comms_cable_FRU_part	Indicates the FRU part number of the battery midplane communication cable.
Battery_EPOW_cable_FRU_part	Indicates the FRU part number of the battery midplane EPOW cable.
local_fc_port_mask	Indicates the FC I/O ports that a system can use for node-to-node communications on a local system if those FC I/O ports exist on a node. The value is 64 binary bits. This field might not apply to your system.
partner_fc_port_mask	Indicates the FC I/O ports that a system can use for system-to-system communications on a partnered system if those FC I/O ports exist on a node. The value is 64 binary bits. This field might not apply to your system.
cluster_topology	Indicates the system topology (set by using the chsystem command). This field might not apply to your system.
site_id	Indicates the site node value. This field might not apply to your system.
site_name	Indicates the site name. This field might not apply to your system.
identify_LED	Indicates that the node or node canister identify LED state (on, off, or blank).
password_reset_enabled	Indicates whether the superuser password reset is enabled (yes or no).
node_location_copy	Indicates the node location copy status. This value is equivalent to the panel name and is blank if a node is removed from a system. This field might not apply to your system.
node_product_mtm_copy	Indicates the node product machine type copy status. This value is equivalent to panel product_mtm; blank if a node is removed from a system. This field might not apply to your system.
node_product_serial_copy	Indicates the node product serial copy status. This value is equivalent to product_serial; blank if a node is removed from a system. This field might not apply to your system.
node_WWNN_1_copy	Indicates the node WWNN first copy status. This value is equivalent to enclosure_WWNN_1; blank if a node is removed from a system. This field might not apply to your system.
node_WWNN_2_copy	Indicates the node WWNN second copy status. This value is equivalent to enclosure_WWNN_2; blank if a node is removed from a system. This field might not apply to your system.
latest_cluster_id	Indicates the system ID running on the current enclosure; blank if a node is removed from a system. This field might not apply to your system.
next_cluster_id	Indicates the system ID running on the current enclosure; blank if a node is removed from a system. This field might not apply to your system.

Table 121. *lsservicestatus* output (continued)

Attribute	Value
techport	<p>Indicates the technician port (for emergency node maintenance):</p> <ul style="list-style-type: none"> • permanent indicates a dedicated technician port. • enabled indicates an enabled technician port. • disabled indicates a disabled technician port. • none indicates that there is no technician port. <p>This applies only to V5000 Gen2 systems.</p>
node_usb	<p>Indicates whether the USB ports are enabled for use (on) or disabled (off). This field might not apply to your system.</p>
rdma_type	<p>A semicolon separated list that displays the RDMA protocol capabilities of the port. This field is blank for non-RDMA capable Ethernet ports.</p>

An invocation example

```
sainfo lsservicestatus
```

[sainfo host](#)

Use the **host** command to change an Internet Protocol (IP) address to a host name or change a host name to an IP address.

[sainfo lsbootdrive](#)

Use the **lsbootdrive** command to return the drive information of the internal boot drives for the specified node. This command applies to SAN Volume Controller 2145-DH8 systems.

[sainfo lscmdstatus](#)

Use the **lscmdstatus** command to display the status of any currently running service-aid task.

[sainfo lsfiles](#)

Use the **lsfiles** command to display the files on the node that you want to retrieve with the **satask cpfiles** command.

[sainfo lshardware](#)

Use the **lshardware** command to view the configured and actual hardware configuration of a node in the system.

[sainfo lsnodediscoverysubnet](#)

Use the **lsnodediscoverysubnet** command to list the IPv4 subnets that are used for local node discovery. This command is available only on cloud systems.

[sainfo lsnodeip](#)

Use the **sainfo lsnodeip** command to list the node IP addresses of Ethernet ports on the node.

[sainfo lsnodeipconnectivity](#)

Use the **sainfo lsnodeipconnectivity** command to list the port level iSER (iSCSI Extensions for RDMA) clustering session connectivity information.

[sainfo lsservicenodes](#)

Use the **lsservicenodes** command to display a list of all the nodes that can be serviced by using the service assistant CLI.

[sainfo lsservicerecommendation](#)

Use the **lsservicerecommendation** command to determine what actions must be completed when you service a node.

[sainfo traceroute](#)

Use the **traceroute** command to print wide area network (WAN) route packets to a specified host.

sainfo traceroute

Use the **traceroute** command to print wide area network (WAN) route packets to a specified host.

Syntax

```
➤ sainfo traceroute  — -ip_or_name  ┌ ip_address  ┐
                               └ host_name  ┘
```

Parameters

-ip_or_name ip_address / host_name

(Required) Specifies the host system IP address or host system name that you want to print WAN route packets to. The value for the IP address must be a standard IPv4 or IPv6 address. The value for the host name must be an alphanumeric string.

Description

This command prints WAN print route packets to a specified host.

An invocation example

```
sainfo traceroute -ip_or_name compass.ssd.hursley.ibm.com
```

The resulting output:

```
traceroute to compass.ssd.hursley.ibm.com (9.71.44.59), 30 hops max, 60 byte packets
 1  9.71.45.4 (9.71.45.4)  0.283 ms  0.337 ms  0.397 ms
 2  compass.ssd.hursley.ibm.com (9.71.44.59)  0.124 ms  0.124 ms  0.113 ms
```

Chapter 25. Service task commands

Use the service task commands to service the node hardware (such as IBM Spectrum Virtualize).

Note: You can find out the *panel_name* for each of your nodes by issuing `satask lsservicenodes`.

`satask addnodediscoverysubnet`

Use the **addnodediscoverysubnet** command to add a node discovery subnet where candidate nodes can be discovered. This command is available only on cloud systems.

Syntax

```
➤ satask — addnodediscoverysubnet — -net — ipv4_subnet/subnet_prefix ➤
```

Parameters

-net

(Optional) Specify the subnet and network prefix notation on which the target node is located.

Description

This command adds a node discovery subnet where candidate nodes can be discovered. There are a total of 16 slots (16 records) in the subnets table. You do not need to specify which slot in the table to store the record. This command finds an available slot automatically for you.

If you add a subnet that has an overlapping IP address with other subnets that are configured on the node or add the same subnet twice, the command fails with an error message.

An invocation example

```
satask addnodediscoverysubnet -net 9.7.8.0/28
```

The resulting output:

```
No feedback
```

[satask chbootdrive](#)

Use the **chbootdrive** command to synchronize a broken drive or field-replaceable unit (FRU) replacement drive [or acknowledge an intentional swap over of boot drives into a replacement canister](#).

[satask chnodeled](#)

Use the **chnodeled** command to turn the identification light-emitting diode (LED) on or off for the specified node or control canister.

[satask chnodeip](#)

Use the **chnodeip** command to set or clear the node IP on the specified node Ethernet port.

[satask chnodeusb](#)

Use the **chnodeusb** command to enable or disable USB ports on the node. This command is for FlashSystem 9100 node types AF7 and AF8 only.

[satask chserviceip](#)

Use the **chserviceip** command to set the service address for a specific node.

[satask chwwnn](#)

Use the **chwwnn** command to modify the node worldwide node name (WWNN). (This command applies to SAN Volume Controller 2145-CG8 and older nodes.)

satask chvpd

Use the **chvpd** command to set vital product data (VPD) such as serial number and machine type.

satask cpfiles

Use the **cpfiles** command to copy files from another node.

satask downloadsoftware

Use the **downloadsoftware** command to download selected code bundles from a Fix Central server. This command can also be used to abort a download.

satask dumpinternallog (Discontinued)

The **dumpinternallog** command has been discontinued.

satask installsoftware

Use the command to install a specific system code package on a single node.

satask leavecluster

Use the **leavecluster** command to remove system state data, location information, and other history from a node.

satask metadata

Use the **metadata** command to recover the critical metadata describing arrays and volumes.

satask mkcluster

Use the **mkcluster** command to create a new system.

mkcluster (Deprecated)

The **mkcluster** system command is deprecated. Use the **satask mkcluster** command to create a new system.

satask overridequorum

Use the **overridequorum** command to start the manual override command.

satask rescuenode

Use the **rescuenode** command to start automatic recovery for a specific node.

satask resetpassword

Use the **resetpassword** command to reset the system superuser password to a user-defined value.

satask restartservice

Use the **restartservice** command to restart a named service.

satask rmnodecoverysubnet

Use the **rmnodecoverysubnet** command to remove a configured subnet and stop it from being used for node discovery. This command is available only on cloud systems.

satask setlocale

Use the **setlocale** command to change the **satask** and **sainfo** command output to the chosen language on the current node.

satask setpacedccu

Use the **setpacedccu** command to flag a node to participate in a user-paced system update.

satask settempsshkey

Use the **settempsshkey** command to install a temporary Secure Shell (SSH) key for a superuser ID to run commands in the service assistant CLI.

satask snap

Use the **satask snap** command to collect diagnostic information from the node and to write the output to a USB flash drive, or to upload specified support information.

satask startservice

Use the **startservice** command to enter a service state.

satask stopnode

Use the **stopnode** command to power off, reboot, or warmstart a node.

[satask stopservice](#)

Use the **stopservice** command to exit a service state.

[satask supportupload](#)

Use the **supportupload** command to upload files to a node or system.

[satask t3recovery](#)

Use the **t3recovery** command to prepare and start a T3 recovery.

satask chbootdrive

Use the **chbootdrive** command to synchronize a broken drive or field-replaceable unit (FRU) replacement drive [or acknowledge an intentional swap over of boot drives into a replacement canister](#).

Syntax

►► satask chbootdrive — -sync — *-replacecanister* — *panel_name* ►

Parameters

-sync

(Required) Specifies synchronization for:

- New drives
- Drives marked out of synchronization
- Drives from another node

-replacecanister

(Optional) Creates an association between the new canister and internal drives by modifying the headers in the persistent data partitions. This parameter is used when a failed control canister is replaced and the boot drives from the failed canister are installed in the replacement canister.

Note: This parameter is only supported on FlashSystem 9100, FlashSystem 9200, Storwize V7000 Gen3, FlashSystem 7200, Storwize V5100, and FlashSystem 5100.

panel_name

(Optional) Specifies the panel name of the node on which to operate.

Note: If *panel_name* is not supplied, this command applies to the node on which the command is running.

Description

The command synchronizes a broken or FRU replacement drive. Specifying the **-sync** causes a node restart on the specified node.

Remember: This command can be run only in service mode (to keep the drive boots synchronized), and can be used only on systems equivalent to SAN Volume Controller 2145-DH8 or the FlashSystem 9100, FlashSystem 9200, Storwize V7000 Gen3, FlashSystem 7200, Storwize V5100, and FlashSystem 5100 systems. Otherwise, use the **chnodebootdrive** command.

An invocation example

```
satask chbootdrive -sync
```

The following output is displayed:

```
No feedback
```

Use the **rmnodediscoverysubnet** command to remove a configured subnet and stop it from being used for node discovery. This command is available only on cloud systems.

satask setlocale

Use the **setlocale** command to change the **satask** and **sainfo** command output to the chosen language on the current node.

satask setpacedccu

Use the **setpacedccu** command to flag a node to participate in a user-paced system update.

satask settempsshkey

Use the **settempsshkey** command to install a temporary Secure Shell (SSH) key for a superuser ID to run commands in the service assistant CLI.

satask snap

Use the **satask snap** command to collect diagnostic information from the node and to write the output to a USB flash drive, or to upload specified support information.

satask startservice

Use the **startservice** command to enter a service state.

satask stopnode

Use the **stopnode** command to power off, reboot, or warmstart a node.

satask stopservice

Use the **stopservice** command to exit a service state.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask chnodeled

Use the **chnodeled** command to turn the identification light-emitting diode (LED) on or off for the specified node or control canister.

Syntax

Parameters

-on | -off

(Required) Turns the identification LED for the specified node or control canister on or off.

-battery | -bootdrive slot

(Optional) Turns the LED on the battery or bootdrive on or off.

Looking at the front of the node:

- The value for the drive on the left side is 1 for slot 1. The value for the drive on the right side is 2 for slot 2.
- The battery on the left goes in the first battery slot (1). The battery on the right goes in the second battery slot (2).

If you specify **-battery** or **-bootdrive**, you must specify *slot*. If you do not specify **-battery** or **-bootdrive**, the node automatically sets the light-emitting diode (LED) identity for the control canister.

This parameter is only available for the SAN Volume Controller product.

panel_name

(Optional) Specifies a unique panel name used to apply the command to a valid node on the fabric.

Note: If `panel_name` is not supplied, this applies to the node on which the command is running.

Description

This command turns the canister identification LED on or off.

Note: The identification LED is mapped onto the physical LEDs using different methods, depending on your hardware. Refer to the documentation for your hardware platform for more information.

An invocation example to turn on the LED to identify the battery in slot 2 on node KP2812

```
satask chnodeled -on -battery 2 KP2812
```

The resulting output:

```
No feedback
```

An invocation example to turn on the LED to identify the battery on node 2

```
satask chnodeled -on -battery 2
```

The resulting output:

```
No feedback
```

An invocation example to allow the node to identify the LED

```
satask chnodeled -on
```

The resulting output:

```
No feedback
```

An invocation example to turn on the LED for canister 1 in control enclosure 02

```
satask chnodeled -on 02-1
```

The resulting output:

```
No feedback
```

satask supportupload

Use the **supportupload** command to upload files to a node or system.

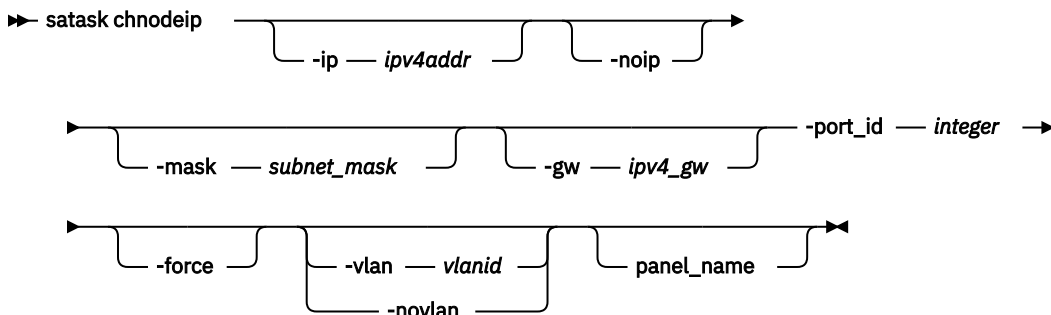

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask chnodeip

Use the **chnodeip** command to set or clear the node IP on the specified node Ethernet port.

Syntax

Parameters

-ip *ipv4addr*

(Optional) Specifies the Internet Protocol Version 4 (IPv4) address for the specified Ethernet port.

-noip

(Optional) Specifies that the IPV4 address be cleared from the specified Ethernet port. The default value is false.

-mask *subnet_mask*

(Optional) Specifies the IPv4 address mask for the specified Ethernet port.

-gw *ipv4_gw*

(Optional) Specifies the IPv4 gateway address for the specified Ethernet port.

-port_id *integer*

(Required) Specifies the port ID on which you want to configure node IP address. The value must be an integer.

-force

(Optional) Forces an IP address change for a node Ethernet port even if it causes the system to go into a degraded or offline state.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

-vlan *vlanid*

(Optional) Specifies the numeric Virtual LAN identifier the clustering port is part of. The value must be an integer.

-novlan

(Optional) Deletes or unsets the numeric Virtual LAN identifier the clustering port is part of.

panel_name

(Optional) Specifies the system or node on which the command is invoked. The value must be an alphanumeric.

Description

This command sets or clears the node IP address on the specified node Ethernet port.

For IBM Spectrum Virtualize for Public Cloud on Amazon Web Services (AWS), if the new IP address is assigned to another instance such as a partner instance, you need to change the IP address to the current instance manually on the AWS console. If the new IP address is assigned to the current instance on the AWS console already, no further action is required.

For IBM Spectrum Virtualize for Public Cloud on Amazon Web Services (AWS), the node IP is configured by the AWS cloud formation template during installation. If you want to change the configuration, follow these steps:

1. Assign an IP to the related Ethernet interface on the AWS EC2 instance.
2. Configure the related IP to the corresponding Ethernet interface. Otherwise, the IP address is invalid and the network connection between nodes might be broken.

Network interface eth1 on the AWS EC2 instance corresponds to eth0 on the system node. Network interface eth2 on the AWS EC2 instance corresponds to eth1 inside system node.

Note: If you receive error message CMMVC8012E - The operation did not complete in the time allowed, rerun the command.

Invocation examples

To set a new port IP address on a node, enter the following command:

```
satask chnodeip -ip 9.7.8.1 -gw 9.0.0.1 -mask 255.255.255.0 -port_id 1
```

The resulting output:

```
No feedback
```

To clear an existing IP address from port 1 on a node, enter the following command:

```
satask chnodeip -noip -port_id 1
```

The resulting output:

```
No feedback
```

To clear an existing IP address from port 2 on a node, enter the following command:

```
satask chnodeip -noip -port_id 2
```

The resulting output:

```
No feedback
```

To clear existing IP addresses from port 1 on a node, enter the following command:

```
satask chnodeip -noip -port_id 1
```

If you want to clear the IP address from port 2, you must rerun the command by specifying the other port ID.

The resulting output:

```
No feedback
```

To assign VLAN to port_id 4, enter the following command:

```
satask chnodeip -ip 40.41.42.50 -mask 255.255.255.0 -gw 40.41.42.1 -vlan 5 -port_id 4
```

The resulting output:

```
No feedback
```

To change VLAN to port_id 4, enter the following command:

```
satask chnodeip -ip 40.41.42.50 -mask 255.255.255.0 -gw 40.41.42.1 -vlan 100 -port_id 4
```

The resulting output:

```
No feedback
```

To remove VLAN from port_id 4, enter the following command:

```
satask chnodeip -novlan -port_id 4
```

The resulting output:

```
No feedback
```

The **dumpinternallog** command has been discontinued.

satask installsoftware

Use the command to install a specific system code package on a single node.

satask leavecluster

Use the **leavecluster** command to remove system state data, location information, and other history from a node.

satask metadata

Use the **metadata** command to recover the critical metadata describing arrays and volumes.

satask mkcluster

Use the **mkcluster** command to create a new system.

mkcluster (Deprecated)

The **mkcluster** system command is deprecated. Use the **satask mkcluster** command to create a new system.

satask overridequorum

Use the **overridequorum** command to start the manual override command.

satask rescuenode

Use the **rescuenode** command to start automatic recovery for a specific node.

satask resetpassword

Use the **resetpassword** command to reset the system superuser password to a user-defined value.

satask restartservice

Use the **restartservice** command to restart a named service.

satask rmnodecoverysubnet

Use the **rmnodecoverysubnet** command to remove a configured subnet and stop it from being used for node discovery. This command is available only on cloud systems.

satask setlocale

Use the **setlocale** command to change the **satask** and **sainfo** command output to the chosen language on the current node.

satask setpacedccu

Use the **setpacedccu** command to flag a node to participate in a user-paced system update.

satask settempsshkey

Use the **settempsshkey** command to install a temporary Secure Shell (SSH) key for a superuser ID to run commands in the service assistant CLI.

satask snap

Use the **satask snap** command to collect diagnostic information from the node and to write the output to a USB flash drive, or to upload specified support information.

satask startservice

Use the **startservice** command to enter a service state.

satask stopnode

Use the **stopnode** command to power off, reboot, or warmstart a node.

satask stopservice

Use the **stopservice** command to exit a service state.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask chnodeusb

Use the **chnodeusb** command to enable or disable USB ports on the node. This command is for FlashSystem 9100 node types AF7 and AF8 only.

Syntax

➤ satask — chnodeusb — 

Parameters

-on | -off

(Required) Setting this parameter to **on** enables USB ports on the node. Setting it to **off** disables USB ports on the node.

panel_name

(Optional) Specifies a unique panel name that is used to apply the command to a valid node on the system.

Note: If `panel_name` is not supplied, this command applies to the node on which the command is running.

Description

This command allows a superuser to change security features on a node. This command cannot be run on active nodes.

An invocation example for -on/-off

```
satask chnodeusb -on/-off
```

The resulting output:

```
No feedback.
```

An invocation example for -on with an unsupported node

```
satask chnodeusb -on
```

The resulting output:

```
CMMVC8008E The command failed because it is not supported.
```

An invocation example for -off [panel_name] using current node

```
satask chnodeusb -off 123456-1
```

The resulting output:

```
CMMVC8000E Cannot execute on an active node.
```

Use the **supportupload** command to upload files to a node or system.

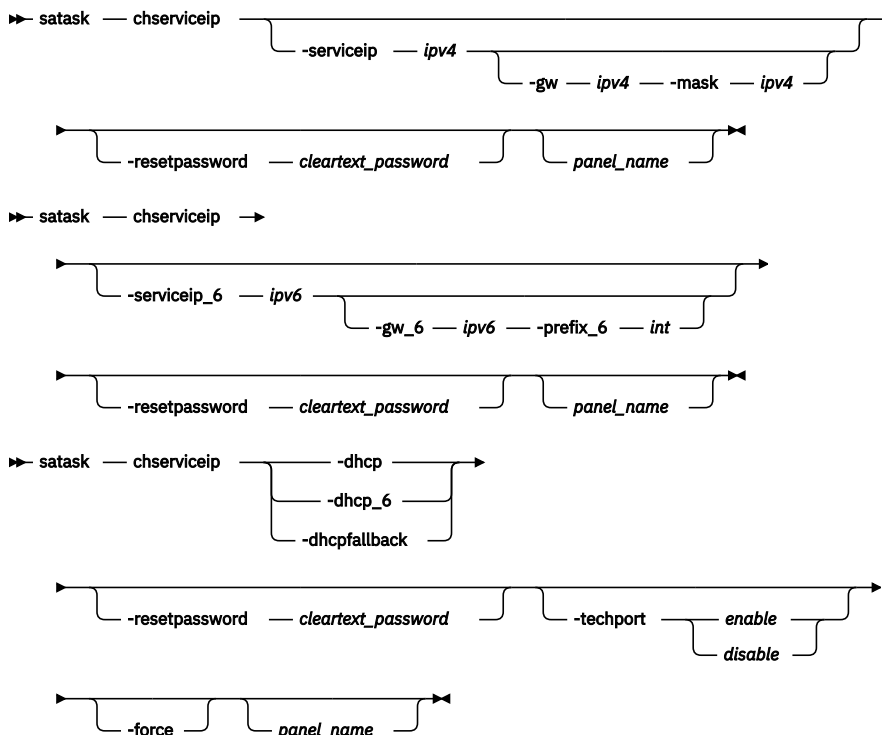

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask chserviceip

Use the **chserviceip** command to set the service address for a specific node.

Syntax

Parameters

panel_name

(Optional) Identifies the node being serviced.

Note: If `panel_name` is not supplied, this applies to the node on which the command is running.

-serviceip

(Optional) The IPv4 address for the service assistant.

Note: The IPv4 service address can be unconfigured by setting the address to `0.0.0.0`.

-gw

(Optional) The IPv4 gateway for the service assistant. If **-gw** is specified, **-mask** must be specified.

-mask

(Optional) The IPv4 subnet for the service assistant. If **-mask** is specified, **-gw** must be specified.

-serviceip_6

(Optional) The Internet Protocol Version 6 (IPv6) address for the service assistant.

Note: The IPv6 service address can be unconfigured by setting the address to `0:0:0:0:0:0:0:0`.

-gw_6

(Optional) The IPv6 gateway for the service assistant. If **-gw_6** is specified, **-prefix_6** must be specified.

-prefix_6

(Optional) The IPv6 prefix for the service assistant. If **-prefix_6** is specified, **-gw_6** must be specified.

-default

(Optional) Resets to the default IPv4 address.

-dhcp

(Optional) Attempts to obtain an IPv4 address from Dynamic Host Configuration Protocol (DHCP).

-dhcp_6

(Optional) Attempts to obtain an IPv6 address from DHCP.

-default

(Optional) Resets the IPv4 service address to the default address.

-resetpassword cleartext_password

(Optional) Sets the service assistant password to **cleartext_password**. The password must be in the range of 6 - 64 characters.

Description

This command sets the service assistant IP address for a specific node. If the node is part of a system, then the system gateway, subnet, and prefix are used unless specified otherwise. If the node is a candidate node, the subnet, prefix, and gateway must be specified. If you specify an IPV4 or IPV6 address, but do not provide a gateway, mask, or prefix, then the existing gateway, mask, and prefix values are preserved.

For IBM Spectrum Virtualize for Public Cloud on Amazon Web Services (AWS), if the new IP address is assigned to another instance such as a partner instance, you need to change the IP address to the current instance manually on the AWS console. If the new IP address is assigned to the current instance on the AWS console already, no further action is required.

For IBM Spectrum Virtualize for Public Cloud on Amazon Web Services (AWS), the service IP is configured by the AWS cloud formation template during installation. If you want to change the configuration, follow these steps:

1. Assign an IP to the related Ethernet interface on the AWS EC2 instance.
2. Configure the related IP to the corresponding Ethernet interface. Otherwise, the IP address is invalid and the network connection between nodes might be broken.

Network interface eth1 on the AWS EC2 instance corresponds to eth0 on the system node. Network interface eth2 on the AWS EC2 instance corresponds to eth1 inside system node.

When **-dhcpfallback** is specified, the current service interface is restarted and the new service IPv4 address is established using DHCP. If the DHCP request fails, the service IP address is set statically based on the node's physical location.

The location is based on the:

- Enclosure location within the chassis
- Node slot within the enclosure

Do not use the **-dhcpfallback** parameter for IPv6. These flags allocate a new address because the command causes the service interface to restart.

Therefore, you can configure both an IPv4 and an IPv6 address concurrently. Setting the IPv4 address does not change the IPv6 setting, and setting the IPv6 address does not change the IPv4 setting. It is possible to clear any values set by setting the IPv4 address to 0.0.0.0 or leaving the IPv6 value empty.

Use the **chserviceip** command to:

- Clear the IPv4 service IP address:

```
satask chserviceip -serviceip 0.0.0.0 -gw 0.0.0.0 -mask 0.0.0.0
```

- Clear the IPv6 service IP address:

```
satask chserviceip -serviceip_6 0::0 -gw_6 0::0 -prefix_6 64
```

Remember:

- If **-gw** is specified, **-mask** must also be specified.
- If **-gw_6** is specified, **-prefix_6** must also be specified.

An invocation example using specific -serviceip, -gw, and -mask parameters

```
satask chserviceip -serviceip 1.2.3.4 -gw 1.2.3.1 -mask 255.255.255.0
```

The resulting output:

```
No feedback
```

An invocation example enabling the technician port on a node

```
satask chserviceip -techport enable -force
```

The resulting output:

```
No feedback
```

satask chwwnn

Use the **chwwnn** command to modify the node worldwide node name (WWNN). (This command applies to SAN Volume Controller 2145-CG8 and older nodes.)

Syntax

► satask — chwwnn — -wwnnsuffix — *wwnn_suffix* — *panel_name* ►

Parameters

-wwnnsuffix *wwnn_suffix*

(Required) Specifies the suffix to be used for node *wwnn*.

panel_name

(Optional) Specifies the node that you are servicing.

Note: If *panel_name* is not supplied, this parameter value applies to the node on which the command is running.

Description

This command modifies the WWNN. Use the **lsservicestatus** command to view suggested WWNNs.

An invocation example

```
chwwnn -wwnnsuffix 000cc
```

The resulting output

```
No feedback
```

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask chvpd

Use the **chvpd** command to set vital product data (VPD) such as serial number and machine type.

Syntax

Parameters

-serial *serial_number*

(Optional) Specifies the serial number for system board or enclosure.

-type *machine_type_model*

(Optional) Specifies the machine model type.

-wwnn *wwnn*

(Optional) Specifies the worldwide node name (WWNN).

wwnn1 *wwnn1*

(Optional) Specifies the WWNN of canister 1.

Note: **wwnn1** will no longer work on node 2, when the **panel_name** is not present.

-wwnn2 wwnn2

(Optional) Specifies the WWNN of canister 2.

Note: **wwnn2** will no longer work with node 1, when the **panel_name** is not present.

-fcportmap physical_port_locations_list | legacy_port_mappings_list | standard_map_name

(Optional) Specifies the FC I/O port location on the node that is mapped to a slot or port.

- Specify **-fcportmap physical_port_locations_list** to associate physical ports with an FC I/O port ID and to use the port WWPNs that are defined for the FC I/O port ID. The physical port location is made up of 2 digits, which represent the slot number (first digit) and port number (second digit).

Note: This value is a comma-separated list of physical port locations.

- Specify **-fcportmap legacy_port_mappings_list** to associate physical ports with an FC I/O port ID and to use the WWPN value that is defined for the port location of the replaced node. Thus, the WWPN for the port on the new node is the same as the mapped port on the replaced node. A legacy port mapping maps a physical port location on the new system to a physical port location on the replaced system.

Note: This value is a comma-separated list of legacy port mappings.

- Specify **-fcportmap standard_map_name** to specify a standard port mapping.

Note: The FC I/O port ID of each port is defined by its position in the list.

-machinepartnumber mpn

(Optional) Specifies the machine part number.

-resetclusterid

(Optional) Resets the system ID to 0.

Note:

- **resetclusterid** will only work on the current node it is on or the one specified by **panel_name**.
- The **resetclusterid** flag will no longer warm start the partner node.
- The partner cluster ID is ignored when clustering.

-idfile file_name

(Optional) Specifies the unique node ID file that allows each supported server to become a unique system node.

panel_name

(Optional) Identifies the node that is used.

-replacemidplane

(Optional) Fills in the details for the FRU part midplane replacement. Using this parameter fills in the following fields:

- The MTM in the midplane VPD, if empty.
- The serial number in the midplane VPD, if empty.
- The personality ID in the midplane VPD, if empty.

Note: There must be a location node error active on the node for this command to be successful.

Note: This parameter is only supported on FlashSystem 9100 and Storwize V7000 Gen3.

Description

The command sets vital product data (VPD), including the serial number, WWPN, machine type, and system ID.

For port location management, the first location represents FC I/O port 1, which is the bit position furthest to the right in the port mask value. Any number of locations can be entered (including for adapters that are not yet installed).

The method for assigning WWPNs is different for each node and is selected automatically based on the WWNN of the node. You must set the mapping in the new node before you add it to the existing clustered system.

Note: When you change the mapping, the node restarts to apply the new setting.

If you specify a WWNN for a legacy node, the port location from the original node must also be specified so that the original WWPN can be assigned. If you use port masking, you must specify the ports in ascending slot or port order (from the original node).

A null mapping (specify `-fcportmap 00`) can be entered, which uses the default mapping. Do not change the port mapping for a node if that node is a member of a clustered system.

Remember: When you specify **chvpd**, one or more nodes might experience a reset or a restart. For example, these parameters might cause a restart:

- **-fcportmap** resets a node or one node canister
- **-idfile** resets a node
- **-serial** restarts both nodes or node canisters
- **-type** restarts both nodes or node canisters
- **-wwnn** resets a node or one node canister

An invocation example that changes the WWNN

```
satask chvpd -wwnn 1111111111111111
```

The resulting output:

```
No feedback
```

An invocation example that changes the WWNN 1 and WWNN 2

```
satask chvpd -wwnn1 1111111111111111 -wwnn2 2222222222222222
```

The following output is displayed:

```
No feedback
```

An invocation example that changes the serial number

```
satask chvpd -serial 8675309
```

The following output is displayed:

```
No feedback
```

An invocation example that changes the WWNN and the FC I/O port location

```
satask chvpd -wwnn 500507680f000123 -fcportmap 31,32,33,34,41,42,43,44,61,62,63,64,71,72,73,74
```

The following output is displayed:

```
No feedback
```

An invocation example that changes the WWNN and the FC I/O port location

```
satask chvpd -wwnn 5005076801000456 -fcportmap  
31-11,32-12,33-13,34-14,41-21,42-22,43-23,44-24,61-31,62-32,63-33,64-34,71-51,72-52,73-53,74-54
```

The following output is displayed:

```
No feedback
```

An invocation example that changes the WWNN and the FC I/O port location

```
satask chvpd -wwnn 5005076801000456 -fcportmap default
```

The following output is displayed:

```
No feedback

Use the **chbootdrive** command to synchronize a broken drive or field-replaceable unit (FRU) replacement drive [or acknowledge an intentional swap over of boot drives into a replacement canister](#).

[satask chnodeled](#)

Use the **chnodeled** command to turn the identification light-emitting diode (LED) on or off for the specified node or control canister.

[satask chnodeip](#)

Use the **chnodeip** command to set or clear the node IP on the specified node Ethernet port.

[satask chnodeusb](#)

Use the **chnodeusb** command to enable or disable USB ports on the node. This command is for FlashSystem 9100 node types AF7 and AF8 only.

[satask chserviceip](#)

Use the **chserviceip** command to set the service address for a specific node.

[satask chwwnn](#)

Use the **chwwnn** command to modify the node worldwide node name (WWNN). (This command applies to SAN Volume Controller 2145-CG8 and older nodes.)

[satask cpfiles](#)

Use the **cpfiles** command to copy files from another node.

[satask downloadsoftware](#)

Use the **downloadsoftware** command to download selected code bundles from a Fix Central server. This command can also be used to abort a download.

[satask dumpinternallog \(Discontinued\)](#)

The **dumpinternallog** command has been discontinued.

[satask installsoftware](#)

Use the command to install a specific system code package on a single node.

[satask leavecluster](#)

Use the **leavecluster** command to remove system state data, location information, and other history from a node.

[satask metadata](#)

Use the **metadata** command to recover the critical metadata describing arrays and volumes.

[satask mkcluster](#)

Use the **mkcluster** command to create a new system.

[mkcluster \(Deprecated\)](#)

The **mkcluster** system command is deprecated. Use the **satask mkcluster** command to create a new system.

satask overridequorum

Use the **overridequorum** command to start the manual override command.

satask rescuenode

Use the **rescuenode** command to start automatic recovery for a specific node.

satask resetpassword

Use the **resetpassword** command to reset the system superuser password to a user-defined value.

satask restartservice

Use the **restartservice** command to restart a named service.

satask rmnodecoverysubnet

Use the **rmnodecoverysubnet** command to remove a configured subnet and stop it from being used for node discovery. This command is available only on cloud systems.

satask setlocale

Use the **setlocale** command to change the **satask** and **sainfo** command output to the chosen language on the current node.

satask setpacedccu

Use the **setpacedccu** command to flag a node to participate in a user-paced system update.

satask settempsshkey

Use the **settempsshkey** command to install a temporary Secure Shell (SSH) key for a superuser ID to run commands in the service assistant CLI.

satask snap

Use the **satask snap** command to collect diagnostic information from the node and to write the output to a USB flash drive, or to upload specified support information.

satask startservice

Use the **startservice** command to enter a service state.

satask stopnode

Use the **stopnode** command to power off, reboot, or warmstart a node.

satask stopservice

Use the **stopservice** command to exit a service state.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask cpfiles

Use the **cpfiles** command to copy files from another node.

Syntax

➤ **satask** — **cpfiles** — **-prefix** — *directory* — **-source** — *source_panel_name* — *file_filter* — *target_panel_name* — **?** ➤

Parameters

satask

System Administrator task; service commands that are only used in specific circumstances.

-prefix directory | file_filter

(Required) Specifies the directory, files, or directory and files to be retrieved. The path must exist in a permitted listable directory. You can use the following -prefix filters:

- /dumps (retrieves all files in all subdirectories)
- /dumps/audit
- /dumps/cimom
- /dumps/cloud
- /dumps/configs
- /dumps/drive
- /dumps/easytier
- /dumps/elogs
- (Storwize V7000)/dumps/enclosure
- /dumps/feature
- /dumps/iostats
- /dumps/iotrace
- /dumps/mdisk
- /dumps/syslogs
- /home/admin/upgrade

Note:

- You can also specify a file filter. For example, if you specify /dumps/elogs/*.txt, all files in the /dumps/elogs directory that end in .txt are copied.
- If you use a wildcard, the following rules apply:
 1. The wildcard character is an asterisk (*).
 2. The command can contain a maximum of one wildcard.
 3. When you use a wildcard, you must surround the filter entry with double quotation marks ("x").
For example: `satask cpfiles -prefix "/dumps/elogs/*.txt"`

-source source_panel_name

(Required) Identifies the source node that the files are copied from.

target_panel_name

(Optional) Identifies the node that files are copied to. If no panel name is provided, the files are copied to the local node.

Note: If target_panel_name is not supplied, this applies to the node on which the command is running.

Description

This command copies files from another node. You can monitor the progress of the copy using the **sainfo lscmdstatus** command.

An invocation example to copy configuration information from canister 1 to enclosure 2

```
satask cpfiles -prefix /dumps/configs -source 02-1
```

The resulting output:

```
No feedback
```

An invocation example to copy Easy Tier information from canister 2 to enclosure 1

```
cpfiles -prefix /dumps/easytier/ -source 01-1 01-2
```

The resulting output:

```
No feedback
```

Use the **chwwnn** command to modify the node worldwide node name (WWNN). (This command applies to SAN Volume Controller 2145-CG8 and older nodes.)

[satask chvpd](#)

Use the **chvpd** command to set vital product data (VPD) such as serial number and machine type.

[satask downloadsoftware](#)

Use the **downloadsoftware** command to download selected code bundles from a Fix Central server. This command can also be used to abort a download.

[satask dumpinternallog \(Discontinued\)](#)

The **dumpinternallog** command has been discontinued.

[satask installsoftware](#)

Use the command to install a specific system code package on a single node.

[satask leavecluster](#)

Use the **leavecluster** command to remove system state data, location information, and other history from a node.

[satask metadata](#)

Use the **metadata** command to recover the critical metadata describing arrays and volumes.

[satask mkcluster](#)

Use the **mkcluster** command to create a new system.

[mkcluster \(Deprecated\)](#)

The **mkcluster** system command is deprecated. Use the **satask mkcluster** command to create a new system.

[satask overridequorum](#)

Use the **overridequorum** command to start the manual override command.

[satask rescuenode](#)

Use the **rescuenode** command to start automatic recovery for a specific node.

satask resetpassword

Use the **resetpassword** command to reset the system superuser password to a user-defined value.

satask restartservice

Use the **restartservice** command to restart a named service.

satask rmnodecoverysubnet

Use the **rmnodecoverysubnet** command to remove a configured subnet and stop it from being used for node discovery. This command is available only on cloud systems.

satask setlocale

Use the **setlocale** command to change the **satask** and **sainfo** command output to the chosen language on the current node.

satask setpacedccu

Use the **setpacedccu** command to flag a node to participate in a user-paced system update.

satask settempsshkey

Use the **settempsshkey** command to install a temporary Secure Shell (SSH) key for a superuser ID to run commands in the service assistant CLI.

satask snap

Use the **satask snap** command to collect diagnostic information from the node and to write the output to a USB flash drive, or to upload specified support information.

satask startservice

Use the **startservice** command to enter a service state.

satask stopnode

Use the **stopnode** command to power off, reboot, or warmstart a node.

satask stopservice

Use the **stopservice** command to exit a service state.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask downloadsoftware

Use the **downloadsoftware** command to download selected code bundles from a Fix Central server. This command can also be used to abort a download.

Parameters

-user *user_name*

(Optional) Specifies a temporary user that is created by the Fix Central server to download an existing code bundle. The value must be an alphanumeric string that is 6 - 64 printable characters in length.

-password *password*

(Optional) Specifies a temporary password that is created by the Fix Central server for the download that is being performed by the temporary user. The value must be an alphanumeric string that is 6 - 64 printable characters in length. **You must enclose the password in single quotation marks.**

-abort

(Optional) Specifies that the download is canceled.

panel_name

(Optional) Specifies the node that is being serviced. The value must be an alphanumeric string.

Note: If not specified, this variable applies to the node on which the command is running.

Description

This command downloads selected code bundles from the Fix Central server. This command can also be used to abort an ongoing download.

Remember: Before you specify this command, you must:

1. Have internet access for all nodes
2. Configure service IP addresses on all nodes in your system.
3. Request your network administration to let the firewall allow connections to the following Internet Protocol (IP) addresses on port 22:
 - 170.225.15.105
 - 170.225.15.104
 - 170.225.15.107
 - 129.35.224.105
 - 129.35.224.104
 - 129.35.224.107
4. Configure a DNS server on your system by specifying **mkdnserver** to define a Domain Name System (DNS) server and **lsdnserver** to display its values.

Before you specify this command, you must log on to the Fix Central server and configure the bundle that you wish to download for your product. Fix Central servers prepare your download bundle and create a temporary user name and password for you. These login credentials are valid for up to 72 hours (during this time you must finish downloading the bundle on to your node or system).

Various software packages might be available depending on your product. This includes new builds for upgrading or downgrading your system, upgrade checking software, remote support proxy server, ifixes, and other software packages. As a part of the download bundle, the Fix Central server generates md5sum output for each file that this command validates the download against. If the md5sum output is not generated in any file, all files downloaded at that point are deleted and the download is aborted.

Specify **lscmdstatus** to display detailed results. For example, specify `sainfo lscmdstatus`:

```
last_command satask downloadsoftware -user mYHJUivw -password '#####'
last_command_status CMMVC8044E Command completed successfully.
T3_status
T3_status_data
cpfiles_status
cpfiles_status_data
snap_status
snap_filename
installcanistersoftware_status
supportupload_status
supportupload_status_data
supportupload_progress_percent 0
supportupload_throughput_KBps 0
supportupload_filename
downloadsoftware_status Active
downloadsoftware_status_data Downloading the bundle
downloadsoftware_progress_percent 38
downloadsoftware_throughput_KBps 321
downloadsoftware_size 467.6 MiB
```

An invocation example

```
satask downloadsoftware -user r0LrhYPf -password 'E4yrr6WZM'
```

The resulting output:

```
No feedback (use lscmdstatus to display software download information)
```

An invocation example

```
satask downloadsoftware -abort
```

The resulting output:

```
No feedback (use lscmdstatus to display software download information)
```

satask supportupload

Use the **supportupload** command to upload files to a node or system.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask installsoftware

Use the command to install a specific system code package on a single node.

Syntax

➔ satask — installsoftware — -file — *filename* — *panel_name* — *-ignore* — *-pacedccu* —

Parameters

-file *filename*

(Required) The file name of code installation package.

Note: The argument to **-file** must be present on the local node; the argument is automatically copied to the target *panel_name*.

-ignore

(Optional) Overrides prerequisite checking and forces installation of the code.

-pacedccu

(Optional) Causes the node to initiate a paced Concurrent Code Update (in which you define when the node begins its update) instead of a normal Concurrent Code Update (in which each node in the clustered system automatically updates in sequence).

panel_name

(Optional) Identifies the node being serviced.

Note: If *panel_name* is not supplied, this applies to the node on which the command is running.

Description

This command installs a specific code package on a single node.

Important: Use this command only under the direction of your support team.

An invocation example

```
satask installsoftware -file install_pkg.gpg nodeB_panel_name
```

The resulting output:

```
No feedback
```

[satask t3recovery](#)

Use the **t3recovery** command to prepare and start a T3 recovery.

satask leavecluster

Use the **leavecluster** command to remove system state data, location information, and other history from a node.

Syntax

```
➤ satask — leavecluster — -force —————▶
                                   |
                                   | panel_name
                                   |
                                   └──────────▶
```

Parameters

-force

(Required) The **-force** parameter is required because this service action can cause temporary or permanent loss of access to data.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

panel_name

(Optional) Identifies the node that is being serviced.

Note: If panel_name is not supplied, this command applies to the node on which the command is running.

Description

Use this command to remove system state data, location information, and other history from a node.

An invocation example

```
satask leavecluster -force 78G00F3-2 /* this forces the node with panel_name=78G00F3-2 out of the clustered system */
```

The resulting output:

```
No feedback
```

An invocation example

```
satask leavecluster -force /* forces the node on which the command is entered out of the clustered system */
```

The resulting output:

```
No feedback
```

An invocation example

```
satask leavecluster
```

The resulting output:

```
CMMVC8034E A compulsory parameter is missing. /* This error message shows when the -force parameter is not specified. */
```

```
CMMVC8001E Cannot execute on a candidate node. /* This error message shows if the current node is not managed. */
```

Use the **rmnodecoverysubnet** command to remove a configured subnet and stop it from being used for node discovery. This command is available only on cloud systems.

[satask setlocale](#)

Use the **setlocale** command to change the **satask** and **sainfo** command output to the chosen language on the current node.

[satask setpacedccu](#)

Use the **setpacedccu** command to flag a node to participate in a user-paced system update.

[satask settempsshkey](#)

Use the **settempsshkey** command to install a temporary Secure Shell (SSH) key for a superuser ID to run commands in the service assistant CLI.

[satask snap](#)

Use the **satask snap** command to collect diagnostic information from the node and to write the output to a USB flash drive, or to upload specified support information.

[satask startservice](#)

Use the **startservice** command to enter a service state.

[satask stopnode](#)

Use the **stopnode** command to power off, reboot, or warmstart a node.

[satask stopservice](#)

Use the **stopservice** command to exit a service state.

[satask supportupload](#)

Use the **supportupload** command to upload files to a node or system.

[satask t3recovery](#)

Use the **t3recovery** command to prepare and start a T3 recovery.

satask metadata

Use the **metadata** command to recover the critical metadata describing arrays and volumes.

Syntax

```
➤ satask — metadata — -rebuildcluster —  -file — filename_arg — -disk ➤  

       -scan  

       UID / IPv4_address / IPv6_address — -start — start_arg —  -end — end_arg ➤  

       -dump ➤
```

Parameters

satask

(Required) Specifies a system administrator task, such as issuing service commands that are only used in specific circumstances.

-rebuildcluster

(Required) Creates a cluster from the metadata found in `/dumps/t3_recovery.bin` created by the `-dump` process.

-scan

(Optional) Scans the specified MDisk or drive for system metadata.

-file filename_arg

(Required) Specifies the file in which you want the results of a scan operation. The file is placed into the node in the directory `/dumps`, and can be retrieved using Secure Copy (**scp**). The file can be subsequently cleaned using the **cleardumps** command.

-disk UID / IPv4_address / IPv6_address

(Required) Specifies the UID, IPv4 address, or IPv6 address of the MDisk or drive that you want to scan or remove a dump from. If an IPv4 or IPv6 address is specified, the **-start** and **-end** parameters are ignored.

-start start_arg

(Required) Specifies the following conditions:

- When used with **-scan**: The first LBA in which to look for metadata on the disk.
- When used with **-dump**: The first LBA at which the metadata resides (as reported in the scan file).

If the `start_arg` variable is not specified, `0` is used as the default.

-end end_arg

(Optional) Specifies the last LBA in which to look for metadata on the disk.

-dump

(Required) Dumps metadata from the specified MDisk or drive to file `/dumps/t3_recovery.bin`

Description

Use this command to recover the critical metadata describing arrays and volumes.

Use the **lscmdstatus** command to see the status of the command.

An invocation example

```
satask metadata -scan -file scan.0.xml -disk 044234043539t530530453453495345430345 -start 0
```

The resulting output:

```
No feedback
```

An invocation example using an IPv4 address.

```
satask metadata -scan -file auto0.xml -disk 192.168.0.1
```

The resulting output:

```
No feedback
```

An invocation example using an IPv6 address.

```
satask metadata -scan -file auto0.xml -disk fe80::a08c:a87:b0ac:a0c2
```

The resulting output:

```
No feedback
```

[satask stopservice](#)

Use the **stopservice** command to exit a service state.

[satask supportupload](#)

Use the **supportupload** command to upload files to a node or system.

[satask t3recovery](#)

Use the **t3recovery** command to prepare and start a T3 recovery.

satask mkcluster

Use the **mkcluster** command to create a new system.

Syntax

►► **satask mkcluster** — **-clusterip** — **-ipv4_ip** — **-gw** — **-ipv4_gw** — **-mask** — **ipv4_mask** —►

└─ **-name** — *cluster_name* ─┐ ┌─ *panel_name* ─┐
└──────────────────────────┘ └──────────────────┘

Parameters

-clusterip *ipv4_ip*

(Optional) The Internet Protocol Version 4 (IPv4) address for system Ethernet port 1.

-gw *ipv4_gw*

(Optional) The IPv4 gateway for system Ethernet port 1.

-mask *ipv4_mask*

(Optional) The IPv4 subnet for system Ethernet port 1.

-clusterip_6 *ipv6_ip*

(Optional) The Internet Protocol Version 6 (IPv6) address for system Ethernet port 1.

-gw_6 *ipv6_gw*

(Optional) The IPv6 gateway for system Ethernet port 1.

-prefix_6 *ipv6_subnet*

(Optional) The IPv6 prefix for system Ethernet port 1.

-name *cluster_name*

(Optional) The name of the new system.

panel_name

(Optional) Identifies the node being serviced.

Note: If *panel_name* is not supplied, this command applies to the node on which the command is running.

Remember: You must specify one of the following:

- IPv4 system IP, gateway, and subnet
- IPv6 system IP, gateway, and prefix

Description

This command creates a new system.

An invocation example that uses specific **-clusterip**, **-gw**, and **-mask** parameters

```
satask mkcluster -clusterip 192.168.1.2 -gw 192.168.1.1 -mask 255.255.255.0
```

The resulting output:

```
No feedback
```

[satask supportupload](#)

Use the **supportupload** command to upload files to a node or system.

[satask t3recovery](#)

Use the **t3recovery** command to prepare and start a T3 recovery.

satask overridequorum

Use the **overridequorum** command to start the manual override command.

Syntax

►► satask overridequorum — -force ►►

Parameters

-force

(Required) Overrides any quorum decision that is made by the system.

Important: Using this option might result in a loss of access. If used incorrectly this command results in different nodes in the system using different copies of mirrored volumes simultaneously. Use this command only for disaster recovery scenarios where all nodes at one site are lost.

Description

This command starts the manual override command. This command is valid on nodes that are in a starting state with either of the following node errors:

- 551
- 921

Remember: This command is only applicable when a system is configured as a HyperSwap or stretched system by specifying:

```
chsystem -topology
```

An invocation example

```
satask overridequorum -force
```

The resulting possible outputs:

```
No feedback
```

```
CMMVC8077E Cluster configured in standard topology. Option is only supported on stretched or hyperswap topology. /* Recover cluster by other means or consider re-designing to use stretched or hyperswap topology. */
```

```
CMMVC8078E Insufficient cluster members to invoke manual recovery. /* Attempt to recover more nodes in site, or seek assistance from IBM support. */
```

```
No more cluster IDs /* Use another node or contact IBM support. */
```

[satask supportupload](#)

Use the **supportupload** command to upload files to a node or system.

[satask t3recovery](#)

Use the **t3recovery** command to prepare and start a T3 recovery.

satask rescuenode

Use the **rescuenode** command to start automatic recovery for a specific node.

Syntax

➔ satask — rescuenode — -force — -secureerase — panel_name ➔

Parameters

panel_name

(Optional) Identifies the node that is being serviced.

Note: If `panel_name` is not supplied, it applies to the node on which the command is running.

-secureerase

(Optional) This parameter securely erases all boot devices and returns the system to the manufactured state.

Note: This parameter is not supported on cloud systems.

-force

(Required) The **-force** parameter is required because this service action can cause temporary or permanent loss of access to data. Use this command only when the node reports corrupted system code.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

Description

This command starts automatic recovery for a specific node. Use this command only when the node reports corrupted code.

This command is not supported for IBM Spectrum Virtualize for Public Cloud on Amazon Web Services (AWS)

Note: If this node communicates to the other nodes in the system by using iSER ports, then use the Service Assistant Tool or the **satask chnodeip** command to set the IP address of the 25-Gbps Ethernet ports that are used for iSER clustering.

An invocation example

```
satask rescuenode -force 112233
```

The resulting output:

```
No feedback
```

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask resetpassword

Use the **resetpassword** command to reset the system superuser password to a user-defined value.

Syntax

➤ **satask** — **resetpassword** — **-password** — **'cleartext_password'** ➤

Parameters

satask

System Administrator task; service commands that are only used in specific circumstances.

-password cleartext_password

(Required) Sets the system superuser password to **'cleartext_password'**. The password must be in the range of 6 - 64 characters. You must enclose the password in single quotation marks.

Description

This command resets the system superuser password to a user-defined value.

An invocation example

```
satask resetpassword -password 'new_password'
```

The resulting output

```
No feedback
```

Use the **overridequorum** command to start the manual override command.

[satask rescuenode](#)

Use the **rescuenode** command to start automatic recovery for a specific node.

[satask restartservice](#)

Use the **restartservice** command to restart a named service.

[satask rmnodecoverysubnet](#)

Use the **rmnodecoverysubnet** command to remove a configured subnet and stop it from being used for node discovery. This command is available only on cloud systems.

[satask setlocale](#)

Use the **setlocale** command to change the **satask** and **sainfo** command output to the chosen language on the current node.

[satask setpacedccu](#)

Use the **setpacedccu** command to flag a node to participate in a user-paced system update.

[satask settempsshkey](#)

Use the **settempsshkey** command to install a temporary Secure Shell (SSH) key for a superuser ID to run commands in the service assistant CLI.

satask snap

Use the **satask snap** command to collect diagnostic information from the node and to write the output to a USB flash drive, or to upload specified support information.

satask startservice

Use the **startservice** command to enter a service state.

satask stopnode

Use the **stopnode** command to power off, reboot, or warmstart a node.

satask stopservice

Use the **stopservice** command to exit a service state.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask restartservice

Use the **restartservice** command to restart a named service.

Syntax

```
➤ satask — restartservice — -service — service_name — panel_name
```

Parameters

satask

Specifies a system administrator's task (such as service commands that are only used in specific circumstances).

-service service_name

(Required) Specifies the name of the service that you want to restart. The following services are supported:

sshd

Specifies a Secure Shell (SSH) Daemon.

slpd

Specifies a Service Location Protocol Daemon.

slv_dpadminpd

Specifies Easy Tier service.

tomcat

Specifies a web server.

cimomserver

Specifies CIMOM.

panel_name

(Optional) Identifies the node that is being serviced.

Note: If panel_name is not supplied, this command applies to the node on which the command is running.

Description

Important: When directed to do so by your product support team, use this command to restart a named service.

An invocation example

```
satask restartservice -service cimomserver
```

The following output is displayed:

```
No feedback
```

[satask startservice](#)

Use the **startservice** command to enter a service state.

[satask stopnode](#)

Use the **stopnode** command to power off, reboot, or warmstart a node.

[satask stopservice](#)

Use the **stopservice** command to exit a service state.

[satask supportupload](#)

Use the **supportupload** command to upload files to a node or system.

[satask t3recovery](#)

Use the **t3recovery** command to prepare and start a T3 recovery.

satask rmnodediscoverysubnet

Use the **rmnodediscoverysubnet** command to remove a configured subnet and stop it from being used for node discovery. This command is available only on cloud systems.

Syntax

```
➤ satask — rmnodediscoverysubnet — -id — subnet_id ➤
```

Parameters

-id subnet_id

(Required) Specify the subnet ID that you want to remove.

Description

This command removes a node discovery subnet from the subnets table.

An invocation example

```
satask rmnodediscoverysubnet -id 1
```

The resulting output:

```
No feedback
```

[satask stopservice](#)

Use the **stopservice** command to exit a service state.

[satask supportupload](#)

Use the **supportupload** command to upload files to a node or system.

[satask t3recovery](#)

Use the **t3recovery** command to prepare and start a T3 recovery.

satask setlocale

Use the **setlocale** command to change the **satask** and **sainfo** command output to the chosen language on the current node.

Syntax

```
➤ satask — setlocale — -locale — locale_id ➤
```

Parameters

-locale locale_id

Specifies the locale ID.

Description

This command changes the language in which error messages are displayed as output from the command-line interface. Subsequently, all error messages from the command-line tools are generated in the chosen language. This command is run when you request a change of language (locale).

Issue the **satask setlocale** command to change the locale setting for the system; all interface output is changed to the chosen language. For example, to change the language to Japanese, type the following:

```
satask setlocale -locale 3
```

where 3 is the value for Japanese. The following values are supported:

- 0 US English (default)
- 1 Simplified Chinese

- 2 Traditional Chinese
- 3 Japanese
- 4 French
- 5 German
- 6 Italian
- 7 Spanish
- 8 Korean
- 9 Portuguese (Brazilian)
- 10 Russian

An invocation example (where 3 is Japanese)

```
satask setlocale -locale 3
```

The resulting output:

```
No feedback
```

An invocation example (where 8 is Korean)

```
satask setlocale -locale 8
```

The resulting output:

```
No feedback
```

Use the **supportupload** command to upload files to a node or system.

[satask t3recovery](#)

Use the **t3recovery** command to prepare and start a T3 recovery.

satask setpacedccu

Use the **setpacedccu** command to flag a node to participate in a user-paced system update.

Syntax

➤ satask — setpacedccu 

Parameters

panel_name

(Optional) Identifies the node being serviced.

Note: If `panel_name` is not supplied, this applies to the node on which the command is running.

Description

Use this command to flag a node to participate in a user-paced system update.

This command can only be used when the node is:

- In a service state
- Error-free
- Not part of a clustered system when the node is out of a service state

An invocation example

```
satask setpacedccu
```

The resulting output:

```
No feedback
```

Use the **stopnode** command to power off, reboot, or warmstart a node.

satask stopservice

Use the **stopservice** command to exit a service state.

[satask supportupload](#)

Use the **supportupload** command to upload files to a node or system.

[satask t3recovery](#)

Use the **t3recovery** command to prepare and start a T3 recovery.

satask settempsshkey

Use the **settempsshkey** command to install a temporary Secure Shell (SSH) key for a superuser ID to run commands in the service assistant CLI.

Syntax

```
➤ satask — settempsshkey — -keyfile — filename —————▶
                                     |
                                     | panel_name
                                     |
                                     ▶
```

Parameters

-keyfile filename

(Required) Specifies the name of the file that contains the Secure Shell (SSH) public key. The file identified by *filename* must be on the local node (or on the USB flash drive, if you execute the command from there).

panel_name

(Optional) Identifies the node being serviced.

Note: If `panel_name` is not supplied, this applies to the node on which the command is running.

Description

This command installs a temporary SSH key for a superuser ID to run commands in the service assistant CLI (for example, to copy files to or from the node).

You can only use this command when completing a service action. Installing a temporary key will replace any available existing keys. The key will be deleted when the node joins a cluster or is rebooted or power cycled.

An invocation example

```
satask settempsshkey -keyfile jvardy12
```

The resulting output:

```
No feedback
```

Use the **stopservice** command to exit a service state.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask snap

Use the **satask snap** command to collect diagnostic information from the node and to write the output to a USB flash drive, or to upload specified support information.

Syntax

Parameters

-dump

(Optional) Indicates the most recent dump file in the output.

-upload

(Optional) Specifies that the snap file be uploaded after it is generated.

-pmr pmr_number

(Optional) Specifies the PMR number to use to upload the snap file. The format for a PMR must be a 13-character alphanumeric string. If the specified PMR is invalid or unknown, it is uploaded to a generic location on the server with the prefix:

```
unknown_pmr_pmr_number_
```

If this option is not supplied, the snap file is uploaded using the machine type and serial number attributes.

-noimm

(Optional) Indicates the /dumps/imm.ffdc file must not be included in the output.

panel_name

(Optional) Indicates the node on which to execute the **snap** command.

Description

This command moves a snap file to a USB flash drive and uploads support information.

If collected, the IMM FFDC file is present in the **snap** archive in /dumps/imm.ffdc.<node.dumptime>.<date>.<time>.tgz. The system waits for up to 5 minutes for the IMM to generate its FFDC. The status of the IMM FFDC is located in the **snap** archive in /dumps/imm.ffdc.log. These two files are not left on the node.

Specify the **lsdumps** command to view the file that you create.

An invocation example

```
satask snap
```

The resulting output:

```
No feedback
```

Important: The name of the output file (placed on the specified node) is `snap.single.nodeid.date.time.tgz`.

An invocation example

```
satask snap -noimm
```

The resulting output:

```
No feedback
```

An invocation example

```
satask snap -dump 111584
```

The resulting output:

```
No feedback
```

Use the **rmnodediscoverysubnet** command to remove a configured subnet and stop it from being used for node discovery. This command is available only on cloud systems.

satask setlocale

Use the **setlocale** command to change the **satask** and **sainfo** command output to the chosen language on the current node.

satask setpacedccu

Use the **setpacedccu** command to flag a node to participate in a user-paced system update.

satask settempsshkey

Use the **settempsshkey** command to install a temporary Secure Shell (SSH) key for a superuser ID to run commands in the service assistant CLI.

satask startservice

Use the **startservice** command to enter a service state.

satask stopnode

Use the **stopnode** command to power off, reboot, or warmstart a node.

satask stopservice

Use the **stopservice** command to exit a service state.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask startservice

Use the **startservice** command to enter a service state.

Syntax

➔ **satask startservice** 

Parameters

satask

(Required) Specifies a system administrator task, such as issuing service commands that are only used in specific circumstances.

-force

(Optional) Overrides checking of system membership.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

panel_name

(Optional) Identifies the node being serviced.

Note: If panel_name is not supplied, this applies to the node on which the command is running.

Description

This command causes a node to go into service state. For example, a user might put a system node into service state to remove it from candidate state or to prevent it from automatically being added to a system again.

The **-force** flag is required if the action could interrupt I/O (last node in cluster or IO group). This command holds the node in service state until it is cleared using the **satask stopservice** command, or until the I/O process is restarted.

An invocation example

```
satask startservice
```

The resulting output:

```
No feedback
```

[satask addnodediscoverysubnet](#)

Use the **addnodediscoverysubnet** command to add a node discovery subnet where candidate nodes can be discovered. This command is available only on cloud systems.

[satask chbootdrive](#)

Use the **chbootdrive** command to synchronize a broken drive or field-replaceable unit (FRU) replacement drive [or acknowledge an intentional swap over of boot drives into a replacement canister](#).

[satask chnodeled](#)

Use the **chnodeled** command to turn the identification light-emitting diode (LED) on or off for the specified node or control canister.

[satask chnodeip](#)

Use the **chnodeip** command to set or clear the node IP on the specified node Ethernet port.

[satask chnodeusb](#)

Use the **chnodeusb** command to enable or disable USB ports on the node. This command is for FlashSystem 9100 node types AF7 and AF8 only.

[satask chserviceip](#)

Use the **chserviceip** command to set the service address for a specific node.

[satask chwwnn](#)

Use the **chwwnn** command to modify the node worldwide node name (WWNN). (This command applies to SAN Volume Controller 2145-CG8 and older nodes.)

[satask chvpd](#)

Use the **chvpd** command to set vital product data (VPD) such as serial number and machine type.

[satask cpfiles](#)

Use the **cpfiles** command to copy files from another node.

[satask downloadsoftware](#)

Use the **downloadsoftware** command to download selected code bundles from a Fix Central server. This command can also be used to abort a download.

[satask dumpinternallog](#) (Discontinued)

The **dumpinternallog** command has been discontinued.

[satask installsoftware](#)

Use the command to install a specific system code package on a single node.

[satask leavecluster](#)

Use the **leavecluster** command to remove system state data, location information, and other history from a node.

[satask metadata](#)

Use the **metadata** command to recover the critical metadata describing arrays and volumes.

[satask mkcluster](#)

Use the **mkcluster** command to create a new system.

[mkcluster](#) (Deprecated)

The **mkcluster** system command is deprecated. Use the **satask mkcluster** command to create a new system.

[satask overridequorum](#)

Use the **overridequorum** command to start the manual override command.

[satask rescuenode](#)

Use the **rescuenode** command to start automatic recovery for a specific node.

[satask resetpassword](#)

Use the **resetpassword** command to reset the system superuser password to a user-defined value.

[satask restartservice](#)

Use the **restartservice** command to restart a named service.

[satask rmnodediscoverysubnet](#)

Use the **rmnodediscoverysubnet** command to remove a configured subnet and stop it from being used for node discovery. This command is available only on cloud systems.

[satask setlocale](#)

Use the **setlocale** command to change the **satask** and **sainfo** command output to the chosen language on the current node.

[satask setpacedccu](#)

Use the **setpacedccu** command to flag a node to participate in a user-paced system update.

[satask settempsshkey](#)

Use the **settempsshkey** command to install a temporary Secure Shell (SSH) key for a superuser ID to run commands in the service assistant CLI.

[satask snap](#)

Use the **satask snap** command to collect diagnostic information from the node and to write the output to a USB flash drive, or to upload specified support information.

satask stopnode

Use the **stopnode** command to power off, reboot, or warmstart a node.

satask stopservice

Use the **stopservice** command to exit a service state.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask stopnode

Use the **stopnode** command to power off, reboot, or warmstart a node.

Syntax

Parameters

-poweroff

(Required if **-reboot** and **-warmstart** are not specified) Powers off the node.

-reboot

(Required if **-poweroff** and **-warmstart** are not specified) Reboots the node.

-warmstart

(Required if **-poweroff** and **-reboot** are not specified) Restarts the I/O process and issues a diagnostic dump (also known as a full dump).

Important: You can also specify `stopsystem -node -reset` to restart the I/O process (but in a more controlled manner).

panel_name

(Optional) Identifies the node being serviced.

Note: If `panel_name` is not supplied, this applies to the node on which the command is running.

Description

Use the **stopnode** command to power off, reboot, or warmstart a node.

An example for powering off canister 1 in enclosure 2

```
satask stopnode -poweroff 02-1
```

The resulting output:

```
No feedback
```

An example for rebooting a node

```
satask stopnode -reboot
```

The resulting output:

```
No feedback
```

Use the **stopservice** command to exit a service state.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask stopservice

Use the **stopservice** command to exit a service state.

Syntax

➤ satask — stopservice  *panel_name*

Parameters

panel_name

Identifies the node that is being serviced.

Note: If *panel_name* is not supplied, this command applies to the node on which the command is running.

Description

This command exits the service state that was entered with the **startservice** command, then exits the service state on the local node.

An invocation example

```
satask stopservice
```

The resulting output

satask startservice

Use the **startservice** command to enter a service state.

satask stopnode

Use the **stopnode** command to power off, reboot, or warmstart a node.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

Syntax

➔ **satask supportupload** 

Parameters

-pmr pmr_number

(Optional) Specifies the PMR (software service request) number that is related to a service report or request. If you do not specify this parameter, the system uses the machine type (MTM) and serial number during the upload. The PMR value that is specified must be a 13-character alphanumeric string in the format ppppp,bbb,ccc, where:

- p indicates PMR.
- b indicates branch.
- c indicates country.

-filename *filename*

(Optional) Specifies the file name to be uploaded. If you do not specify this parameter, the system uses the most recent snap file that is available in the /dumps directory to upload. The value that is specified must be a 256-character alphanumeric string.

-help

(Optional) Specifies that usage information is displayed.

-abort

(Optional) Specifies upload cancellation.

panel_name

(Optional) Specifies the node that is being serviced. The value must be an alphanumeric string.

Note: If not specified, this variable applies to the node on which the command is running.

Description

This command starts or stops node or system file uploads.

Note: If you do not specify a PMR number, files are uploaded to the server (MTSM specific location) under machine type and serial number attributes. Any user can specify this CLI command.

If you specify an incorrect, invalid, or unknown PMR, the files are uploaded to the system with the prefix `unknown_pmr_pmrnumber_filename`.

Remember: Before you specify this command:

1. Make sure that you have internet access for all nodes.
2. Configure service IP addresses on all nodes in your system.
3. Request your network administration to let the firewall allow connections to the following Internet Protocol (IP) addresses on port 443:
 - 129.42.56.189
 - 129.42.54.189
 - 129.42.60.189
4. Configure a DNS server by specifying **mkdnserver** to define a Domain Name System (DNS) server and **lsdnserver** to display its values.

If you specify this command on a remote node, the upload completes by using the service IP address and port of that remote node.

Note: Only one file upload at one time is supported per node.

Do not specify the **supportupload** and **snap** commands simultaneously to upload files, or a message that indicates an upload is in progress is displayed. One upload can be completed at one time per node by using `supportupload/snap/svc_snap`.

Remember: Specify **lscmdstatus** to display detailed results. For example, specify **sainfo lscmdstatus**:

```
last_command satask supportupload -pmr 79556,019,866
last_command_status CMMVC8044E Command completed successfully.
T3_status
T3_status_data
cpfiles_status
cpfiles_status_data
snap_status
snap_filename
installcanistersoftware_status
supportupload_status Active
supportupload_status_data Uploading
supportupload_progress_percent 56
supportupload_throughput_KBps 99939
supportupload_filename /dumps/snap.single.7830619-1.161219.161359.tgz
downloadsoftware_status
downloadsoftware_status_data
downloadsoftware_progress_percent 0
```

```
downloadsoftware_throughput_KBps 0
downloadsoftware_size
```

An invocation example

```
satask supportupload -abort
```

The resulting output:

```
No feedback (use lscmdstatus to display support upload information)
```

An invocation example

```
satask supportupload -pmr 79556,019,866 -filename /dumps/snap.single.7830619-1.161219.161359.tgz
```

The resulting output:

```
No feedback (use lscmdstatus to display support upload information)
```

satask stopservice

Use the **stopservice** command to exit a service state.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

satask t3recovery

Use the **t3recovery** command to prepare and start a T3 recovery.

Syntax

```
➤ satask — t3recovery — -prepare ————— ➤
                        |
                        | -execute
                        |
                        | panel_name
```

Parameters

panel_name

Identifies the node that is being serviced.

Note: If `panel_name` is not supplied, this recovery applies to the node on which the command is running.

-prepare

Search for T3 recovery data. This parameter locates the necessary backup file by date and the quorum disk.

-execute

Start T3 recovery with recovered data.

Description

This command prepares and starts a T3 recovery.

Important: Progress of a T3 recovery can be displayed with the **sainfo lscmdstatus** command.

An invocation example

```
satask t3recovery -prepare
```

The resulting output

```
No feedback
```

An invocation example

```
satask t3recovery -execute
```

The resulting output

```
No feedback
```

Use the **stopnode** command to power off, reboot, or warmstart a node.

satask stopservice

Use the **stopservice** command to exit a service state.

satask supportupload

Use the **supportupload** command to upload files to a node or system.

Chapter 26. Service node information commands

Service node information (sninfo) commands output information about the nonce and the status of the IBM Cloud bare metal server host machine. The service node task (sntask) commands and sninfo commands reside on the bare metal server and are not part of the command line interface of the IBM Spectrum Virtualize for Public Cloud system.

The **sntask** and **sninfo** commands are installed as part of the package that is installed during the automatic or manual installation. The installation also creates the user (sv_cloud) for running the commands. The task commands gather information that is required to load the software and configure and manage the IBM Spectrum Virtualize for Public Cloud node. The **sninfo** commands output information about the nonce and the status of the installed IBM Spectrum Virtualize for Public Cloud node.

To use the **sntask** and **sninfo** commands, **ssh** to the bare metal server as the sv_cloud user. Log in with an SSH key, if possible, or with the sv_cloud password if you did not yet create and install an SSH key pair. Set the initial password for the sv_cloud user from the root user if the password is not yet set.

```
# passwd sv_cloud
```

To create the SSH key pair, refer to the RHEL man pages for a description of how to use the **ssh-keygen -t rsa** terminal command. To create the key pair from a Microsoft Windows system, use the `puttygen.exe` utility, as described in the PuTTY documentation.

To bypass the default session time limit for the SSH session, use **ssh** with the **TCPKeepAlive** option:

```
$ ssh server_name -l sv_cloud -o TCPKeepAlive=yes
```

You are prompted for the password if you are not using an SSH key. To change the sv_cloud password when a password exists, use the sv_cloud user to run the following terminal command:

```
$ passwd sv_cloud
```

You can now run **sntask** and **sninfo** commands.

sninfo lsnodestatus

Use the **sninfo lsnodestatus** command to display current information about the node. This command is for IBM Spectrum Virtualize for Public Cloud only..

Syntax

➤ sninfo lsnodestatus ➤

Parameters

None

Description

This command lists details about the node status for IBM Spectrum Virtualize for Public Cloud implementations.

This table provides the attribute values that can be displayed as output view data.

Table 122. *sninfo lsnodestatus* output

Attribute	Description
panel_name	Indicates the node panel name.
host_serial_number	Indicates the serial number that is indicated on the system web page.
host_instance_id	Indicates the Amazon Web Services (AWS) instance ID.
host_name	Indicates the node server's host name.
current_host_type	Indicates the current AWS EC2 instance type.
installed_host_type	Indicates the first installed AWS EC2 instance type on the node.
serviceip	Indicates the current node service IP address.
node_status	<p>Indicates the running node status. The status values for IBM Cloud implementations are:</p> <ul style="list-style-type: none"> failed - Indicates that the node failed. inactive - Indicates that the node is inactive. active - Indicates that the node is active. <p>The status values for AWS environments are:</p> <ul style="list-style-type: none"> running - Indicates that the container is running. stopped - Indicates that the container is exited. not-initialized - Indicates that the container is not initialized and the user needs to run <code>sntask initnode</code>. service - Indicates that the container is stopped and the host is in service mode.
url	This URL provides the details of the bare metal server in IBM Cloud or the docker host instance in AWS. For AWS, this value consists of the host_instance_id and the VM region that is obtained from the AWS API.
version	Indicates the version of the current node. This value is blank for IBM Cloud implementations.
info	Indicates the host side error or warning information for the node.

Note: When the **node_status** is not running, all other fields are blank except for **node_status**. The fields **host_instance_id**, **host_name**, and **url** are always empty on non-AWS environments.

An invocation example

```
sninfo lsnodestatus
```

The following output is displayed:

```
panel_name: B017V7X
host_serial_number: SL017V7X
host_name: bm02
current_host_type: c5.4xlarge
installed_host_type: c5.9xlarge
serviceip: 10.112.17.35
node_status: active

url: https://cloud.ibm.com/classic/devices/details/510763
```

An invocation example

```
sninfo lsnodestatus
```

The following output is displayed:

```
panel_name: B0WEST1
host_instance_id: i-0f57974b8a3cc1b05
host_name: ip-172-31-31-198.us-west-2.compute.internal
current_host_type: c5.4xlarge
installed_host_type: c5.9xlarge
serviceip: 10.112.17.35
node_status: running
url: https://us-west-2.console.aws.amazon.com/ec2/v2/home?region=us-west-2#Instances:instanceId=i-0f57974b8a3cc1b05
version: 8.1.3.1-143.5.00000000000000
```

An invocation example

```
sninfo lsnodestatus
```

The following output is displayed:

```
panel_name:
host_instance_id: i-0e3b36fa8b3994bff
host_name: ip-172-31-31-167.us-west-2.compute.internal
current_host_type: c5.4xlarge
installed_host_type: c5.9xlarge
serviceip:
node_status: stopped
url: https://us-west-2.console.aws.amazon.com/ec2/v2/home?region=us-west-2#Instances:instanceId=i-0e3b36fa8b3994bff
version:
info: CMMSV1081E The AWS EC2 instance type can not be changed from the first installed type c5.9xlarge to target type c5.4xlarge.
```

sninfo lsnonce

Use the **sninfo lsnonce** command to list the unique nonce code for the IBM Cloud bare metal server. You use the nonce as input to activate the node and generate the Spectrum Virtualize Node Activation Key file (USVNID). (See the installation topic for a description of the steps involved to activate the node.) This command is not available for Amazon Web Services (AWS). This command is for IBM Spectrum Virtualize for Public Cloud only.

Syntax

```
➤ sninfo lsnonce ➤
```

Parameters

None

Description

This command returns the unique nonce for the IBM Cloud bare metal server. Use the nonce when activating the node and generating the USVNID key file.

An invocation example of sninfo lsnonce

```
sninfo lsnonce
```

The resulting output:

```
# sninfo lsnonce  
6ADCB0
```

Chapter 27. Service node task commands

Service node task (**sntask**) commands are used during the initial installation of IBM Spectrum Virtualize for Public Cloud software onto an IBM Cloud bare metal server or Amazon Web Services (AWS) container and afterward to manage the IBM Spectrum Virtualize for Public Cloud node on the bare metal server or AWS container. For example, you might start the node with **sntask startnode** and stop the node with **sntask stopnode**. On IBM Cloud, the **sntask** commands and service node information (**sninfo**) commands reside and run as terminal commands on the Red Hat Enterprise Linux (RHEL) 7 operating system of the bare metal server. On AWS, the **sntask** commands and service node information (**sninfo**) commands reside and run as terminal commands on the CentOS operating system of the EC2 instances.

The **sntask** and **sninfo** commands are installed as part of the package that is installed during the automatic or manual installation. The installation also creates the user (sv_cloud) for running the commands. The task commands gather information that is required to load the software and configure and manage the IBM Spectrum Virtualize for Public Cloud node. The **sninfo** commands output information about the nonce and the status of the installed IBM Spectrum Virtualize for Public Cloud node.

To use the **sntask** and **sninfo** commands, **ssh** to the bare metal server as the sv_cloud user. Log in with an SSH key, if possible, or with the sv_cloud password if you did not yet create and install an SSH key pair. Set the initial password for the sv_cloud user from the root user if the password is not yet set.

```
# passwd sv_cloud
```

To create the SSH key pair, refer to the RHEL man pages for a description of how to use the **ssh-keygen -t rsa** terminal command. To create the key pair from a Microsoft Windows system, use the **puttygen.exe** utility, as described in the PuTTY documentation.

To bypass the default session time limit for the SSH session, use **ssh** with the **TCPKeepAlive** option:

```
$ ssh server_name -l sv_cloud -o TCPKeepAlive=yes
```

You are prompted for the password if you are not using an SSH key. To change the sv_cloud password when a password exists, use the sv_cloud user to run the following terminal command:

```
$ passwd sv_cloud
```

You can now run **sntask** and **sninfo** commands.

sntask applysecuritypatch

Use the **sntask applysecuritypatch** command to apply available security patches on the Amazon Web Services (AWS) host system. This command is for Amazon Web Services (AWS) only.

Syntax

➤ applysecuritypatch  *patch_name*

Parameters

patch_name

(Optional) Specifies the name of the patch. You can specify one or several patches, which are separated by a blank space. If you do not specify a patch name, the command tries to apply all available patches.

Description

This command applies available security patches on the host system.

Note: The host must be placed in service mode by using the **startservice** command before you can apply security patches.

An invocation example

```
sntask applysecuritypatch firefox
```

The following output is displayed:

```
Info: firefox is not installed on your system, it does not need to apply patch for it.  
Security patches have been applied!
```

sntask chnode

Use the **sntask chnode** command to change IBM Spectrum Virtualize for Public Cloud node information that is related to the bare metal server in the IBM Cloud. This command is not available for AWS. This command is for IBM Spectrum Virtualize for Public Cloud only.

Syntax

```
➤ sntask chnode  — -id — node_id ————— ➤  
                  | — -name — node_name — |  
  
➤ sntask chnode  — -name — node_name ————— ➤  
                  | — -id — node_id — |
```

Parameters

-id *node_id*

(Optional) Specifies the node ID to change. The value must be a number.

-name *node_name*

(Optional) Specifies the node name to change. The value must be an alphanumeric string.

Description

This command changes IBM Cloud system node information. You can use this command to set specific values for the bare metal server after you complete the initialization of the IBM Spectrum Virtualize for Public Cloud node. All parameters that are associated with this command are optional. However, you must specify one or more parameters.

An invocation example

```
chnode -name baremetal1
```

The following output is displayed:

```
No feedback
```

sntask cleansnap

Use the **sntask cleansnap** command to delete log files from the system. Both the **satask snap** command and the **sntask snap** command create the log files. This command is for IBM Spectrum Virtualize for Public Cloud only.

Syntax

➤ sntask cleansnap ➤

Parameters

No parameters

Description

This command deletes most of the log files in the `/var/log/SpectrumVirtualize/` directory on the host.

Running the **satask snap** command automatically calls the **sntask snap** command to create the log files and a .tar file of the logs on the host computer. You can also run the **sntask snap** command directly to create the log files on the host computer.

The **sntask cleansnap** command erases the .tar file and all log files on the host computer except for an operating system log for debugging purposes.

Running the **satask snap** command creates log files, memory dumps, and the log files from the host computer in a .tar file in the `/dumps/` directory within the system. To clean up the `/dumps/` directory if space is unavailable or for any other reason, use the **cleardumps** command.

An invocation example of sntask cleansnap

```
sntask cleansnap
```

The following output is displayed:

```
snap tarballs under /var/log/SpectrumVirtualize have been cleaned up.
```

sntask initnode

Use the **initnode** command to initialize the IBM Spectrum Virtualize for Public Cloud software in the IBM Cloud or Amazon Web Services (AWS) environment. This command is for IBM Spectrum Virtualize for Public Cloud only.

Syntax

```
➤ initnode — -sip — service_ip — -gw — gateway_ip — -mask — mask — -netdev →  
  
➤ — network_device_names — -serial — unique_serial_number →  
  
➤ — -nodeip1 — node_ip_1 — — -nodegw1 — node_gateway_1 —  
  
➤ — -nodemask1 — node_mask_1 — — -nodeport1 — port ID of node_ip_1 —  
  
➤ — -nodeip2 — node_ip_2 — — -nodegw2 — node_gateway_2 —  
  
➤ — -nodemask2 — node_mask_2 — — -nodeport2 — port ID of node_ip_2 —  
  
➤ — -id — server_ID — — -name — server_name — — -force —  
  
➤ — -reboot — ➤
```

Parameters

-sip

(Required) Specifies the service IP address of the node. The format of this IP address is IPv4.

-gw

(Required) Specifies the gateway IP address of the node. The format of this IP address is IPv4.

-mask

(Required) Specifies the subnet mask of the service IP address. The format of this IP address is IPv4.

-netdev

(Required) Specifies the network interface names on the host. Two network interface names that are separated by a colon are required (example: eth0:eth1). This parameter is only for AWS.

-serial

(Required) Specifies a unique serial number for the node.

-nodeip1

(Optional) Specifies the node IP address for port 1.

-nodegw1

(Optional) Specifies the gateway address for port 1.

-nodemask1

(Optional) Specifies the subnet mask for port 1.

-nodeport1

(Optional) Specifies the port ID for port 1.

-nodeip2

(Optional) Specifies the node IP address for port 2.

-nodegw2

(Optional) Specifies the gateway address for port 2.

-nodemask2

(Optional) Specifies the subnet mask for port 2.

-nodeport2

(Optional) Specifies the port ID for port 2.

-id *ID*

(Optional) Specifies the bare metal server ID from IBM Cloud. This parameter is not available for AWS.

-name *server_name*

(Optional) Specifies the bare metal server name from IBM Cloud. This parameter is not available for AWS.

-force or -f

(Optional) Specifies to install the IBM Spectrum Virtualize for Public Cloud node without the partition template from the target hard disk. On some supported data centers in IBM Cloud, an empty partition template cannot be selected, creating a partition by default. The partition can cause space limitations for the initialization in the /dev/sdb directory where the software is stored. If you are completing either an automatic or manual installation of the software, you must specify the **-force or -f** parameter to ensure that the partition template is empty. If the /dev/sdb directory contains data, back up the data to another location. This parameter is not available for AWS.

-reboot

(Optional) Specifies to restart the server if necessary after initialization. This parameter is not available for AWS.

Description

This command initializes the IBM Spectrum Virtualize for Public Cloud software in the IBM Cloud.

An invocation example

```
sntask initnode -sip service_ip -gw gateway_ip -mask mask -serial serial_number -force
```

The following output is displayed:

```
Spectrum-virtualize node will be installed on /dev/sdb
Downloading, it may take a few minutes.
Installing, it may take a few minutes
Spectrum-virtualize node is successfully installed
```

An invocation example for AWS

```
sntask initnode -sip 172.31.47.37 -gw 172.31.32.1 -mask 255.255.240.0 -netdev eth0:eth1
1 -nodeip1 172.31.47.128 -nodegw1 172.31.32.1 -nodemask1 255.255.240.0 -nodeport1
2 -nodeip2 172.31.34.222 -nodegw2 172.31.32.1 -nodemask2 255.255.240.0 -nodeport2
```

The following output is displayed:

```
CMMSV1034I Downloading the image https://s3-us-west-2.amazonaws.com/svcloud-dev/image/
190508_1400_container.tgz, which can take a few minutes.
CMMSV1036I Download image succeeded.
CMMSV1023I The node has successfully initialized. Reboot the node.
```

sntask rmnode

Use the **sntask rmnode** command to erase the virtual machine image when you uninstall the IBM Spectrum Virtualize for Public Cloud software from the IBM Cloud host or Amazon Web Services (AWS).

Syntax

➤ **rmnode**  **-force or -f** ➤

Parameters

-force or -f

(Optional) Specifies to force the erasure of the virtual machine image when you uninstall the system from the IBM Cloud bare metal server.

Important: Using the **-force** parameter might result in a loss of access. Use it only under the direction of support personnel.

Description

This command erases the virtual machine image when you uninstall the system from the IBM Cloud host or Amazon Web Services (AWS) host. This step is the first step of uninstalling the product. You must use the **yum remove spectrum-virtualize** command for IBM Cloud or the **yum remove sv-cloud** command for AWS to remove other files.

An invocation example

```
sntask rmnode
```

The following output is displayed:

```
Remove the node on /dev/sdb: [y/n] y
Spectrum-virtualize node is removed.
```

sntask snap

Use the **sntask snap** command to collect the host machine debugging logs. The **satask snap** command automatically calls the **sntask snap** command to also include the host machine logs with its system logs. This command is for IBM Spectrum Virtualize for Public Cloud only.

Syntax

➤ **sntask snap** ➤

Parameters

No parameters

Description

This command collects the host machine debugging logs. The log files are placed in `/var/log/SpectrumVirtualize/`. A `tgz` file is copied to the node under the `/dumps/` directory.

Although the **sntask snap** command is automatically called when you run the **satask snap** command, sometimes you might need to create the host machine logs for host debugging.

For IBM Spectrum Virtualize for Public Cloud on Amazon Web Services (AWS), root access is revoked. You must use the `sv_sftp` account to retrieve the logs from the host.

An invocation example

```
sntask snap
```

The following output is displayed:

```
Log saved to /var/log/SpectrumVirtualize/debug.host03.20170818.005917.tgz
```

sntask startnode

Use the **sntask startnode** command to power on an IBM Spectrum Virtualize for Public Cloud node that is on IBM Cloud or Amazon Web Services (AWS).

Syntax

```
➤ sntask startnode ➤
```

Parameters

No parameters

Description

This command powers on a node that is on an IBM Cloud system host or AWS docker host.

An invocation example

```
sntask startnode
```

The following output is displayed:

```
The node started successfully.
```

sntask startservice

Use the **sntask startservice** command to enter a service mode state for IBM Spectrum Virtualize for Public Cloud on AWS. This command is for IBM Spectrum Virtualize for Public Cloud on AWS only.

Syntax

```
➤ sntask startservice ➤
```

Parameters

No parameters.

Description

This command causes a node to go into a service mode state. For example, an administrator can put a system node into a service state to apply security patches.

An invocation example

```
sntask startservice
```

The resulting output:

```
No feedback
```

sntask stopnode

Use the **sntask stopnode** command to power off an IBM Spectrum Virtualize for Public Cloud node that is on IBM Cloud or Amazon Web Services (AWS). This command is for IBM Spectrum Virtualize for Public Cloud only.

Syntax

➤ sntask stopnode 

Parameters

-poweroff

(Optional) If specified and the AWS host is not in service mode, this flag powers off the host after the container is stopped. This parameter is only available for AWS.

-reboot

(Optional) If specified, the AWS host restarts if it is in service mode. This parameter is only available for AWS.

Description

This command powers off a node that is on an IBM Cloud system host or AWS host.

An invocation example

```
sntask stopnode
```

The following output is displayed:

```
No feedback
```

sntask stopservice

Use the **sntask stopservice** command to exit a service mode state for IBM Spectrum Virtualize for Public Cloud on AWS. This command is for IBM Spectrum Virtualize for Public Cloud on AWS only.

Syntax

➤ sntask stopservice ➤

Parameters

No parameters.

Description

This command causes a node to exit service mode state.

An invocation example

```
sntask stopservice
```

The resulting output:

```
No feedback
```

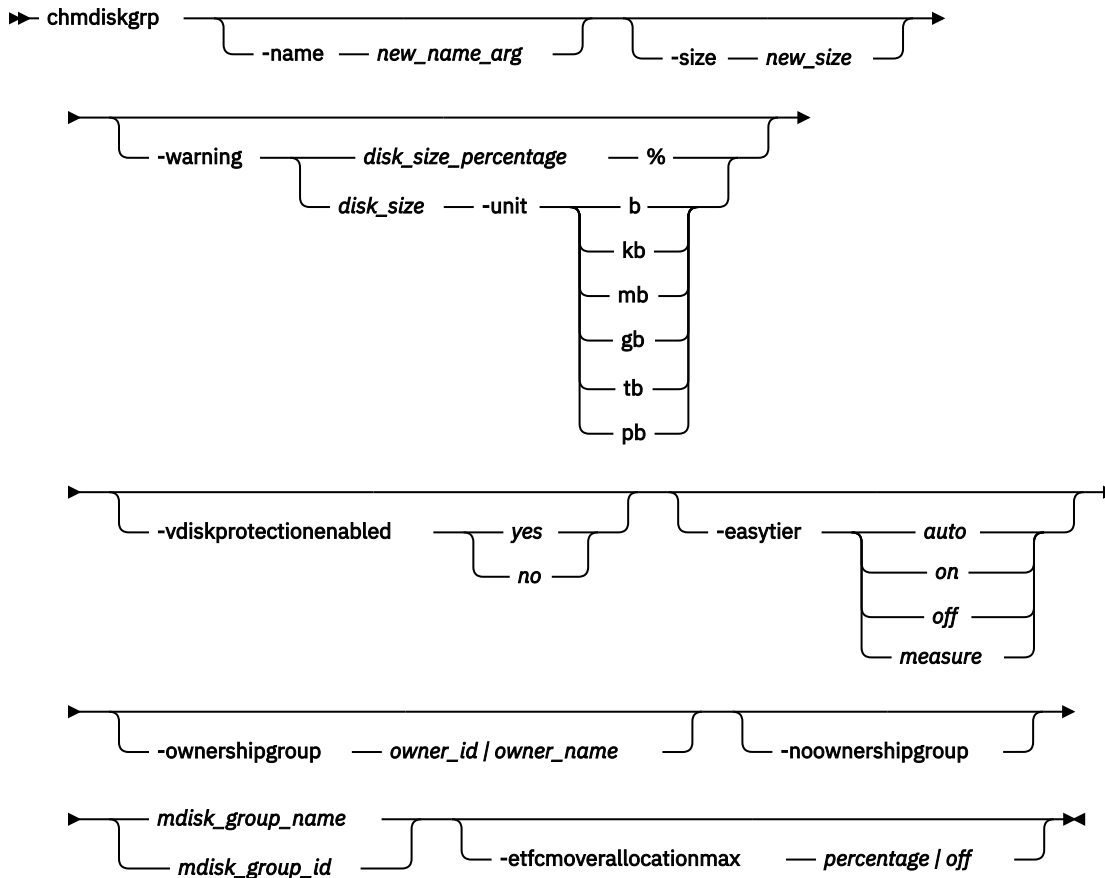

Chapter 28. Storage pool commands

Use the storage pool commands to work with storage pool options on the system.

chmdiskgrp

Use the **chmdiskgrp** command to modify the name that is assigned to a storage pool or to set the warning threshold for the storage pool. You can also change the ownership group.

Syntax

Parameters

-name new_name_arg

(Optional) Specifies the new name of the storage pool.

-warning disk_size / disk_size_percentage %

(Optional) Sets a threshold at which a warning is generated. The warning is generated the first time that the threshold is exceeded by the used-disk capacity in the storage pool. You can specify a *disk_size* integer, which defaults to megabytes (MB) unless the **-unit** parameter is specified; or you can specify a *disk_size_percentage* %, which is a percentage of the storage pool size. To disable warnings, specify **0** or **0%**.

-size new_size

(Optional) Specifies the new size of a child pool.

Note: This parameter cannot be used with parent pools. Use **addmdisk** or **rmmdisk** to change storage pool capacity.

-unit b | kb | mb | gb | tb | pb

(Optional) Specifies the data units for the **-warning** parameter.

-vdiskprotectionenabled yes / no

(Optional) Specifies whether volume protection is enabled for this storage pool.

-easytier auto / on / off / measure

(Optional) Specifies whether the Easy Tier function is on or off for this storage pool, or if it is automatically determined. **-easytier** is active in storage pools with multiple tiers and is balance with single tiers.

Note: **-easytier** must be followed by one of the following:

- If **-easytier** is set to *auto*, SAN Volume Controller automatically enables Easy Tier functions when the storage pool contains MDisk from more than one tier, and enables automatic rebalancing when the storage pool contains MDisk from only one tier.
- If **-easytier** is set to *on*, then Easy Tier functions are active.
- If **-easytier** is set to *off*, then Easy Tier functions are inactive.
- If **-easytier** is set to *measure* Easy Tier statistics are collected but Easy Tier management is disabled. (No extents are moved by Easy Tier.)

auto equates to:

- *on* if Easy Tier is licensed or no license is required.
- *off* if Easy Tier is not licensed and a license is required.

Specifying **-easytier on** enables Easy Tier:

- Management of both single-tier and multi-tier pools
- Auto rebalance

Extents are moved to balance the I/O load on the MDisk in the pool.

-ownershipgroup owner_id / owner_name

(Optional) The name or ID of the ownership group to which the object is being added. This parameter can be specified on child pools only.

-noownershipgroup

(Optional) If specified, the object is removed from the ownership group to which it belongs. This parameter can be specified on child pools only.

mdisk_group_id / mdisk_group_name

(Required) Specifies the ID or name of the storage pool to modify.

-etfcmoverallocationmax percentage / off

(Optional) Sets the maximum over allocation which Easy Tier can migrate onto FlashCore Module arrays, when the array is used as the top tier in a multitier pool. The value acts as a multiplier of the physically available space. The allowed values are a percentage in the range of 100% (default) to 400% or **off**. Setting the value to **off** disables this feature.

Description

Table 123. Parameter differences for child pools and parent pools		
Parameter	Child pool usage	Storage pool usage
-name	Optional	Optional
-easytier	Cannot be used with child pools	Optional
-size	Optional	Cannot be used with parent pools
-unit	Optional	Optional
-warning	Optional	Optional

This command modifies the name, or label, assigned to a given storage pool. You can use the new name to refer to the storage pool.

The command can also be used to set the warning threshold for the storage pool. The warning threshold is the threshold which a warning is generated when it is exceeded by the used-disk capacity in the storage pool.

You can also use this command to change other settings for parent pools and child pools.

An invocation example

```
chmdiskgrp -name testmdiskgrp -easytier on Group0
```

The resulting output:

```
No feedback
```

An invocation example

```
chmdiskgrp -size 100 -unit tb mypool
```

The resulting output:

```
No feedback
```

An invocation example changing the ownership of an mdiskgrp

```
chmdiskgrp chmdiskgrp -ownershipgroup 2 mymdiskgrp
```

The resulting output:

```
No feedback
```

An invocation example moving the mdiskgrp to no ownership

```
chmdiskgrp chmdiskgrp -noownershipgroup mymdiskgrp
```

The resulting output:

```
No feedback
```

An invocation example

This example adds volume protection to StoragePool2.

```
chmdiskgrp -vdiskprotectionenabled yes StoragePool2
```

The resulting output:

```
No feedback
```

Related reference

[lsfreeextents](#)

Use the **lsfreeextents** command to list the number of free extents that are available on a specified MDisk.

[lsmdiskgrp](#)

Use the **lsmdiskgrp** command to display a concise list or a detailed view of storage pools that are visible to the system.

[mkmdiskgrp](#)

Use the **mkmdiskgrp** command to create a new storage pool.

[rmmdisk](#)

Use the **rmmdisk** command to delete a managed disk (MDisk) from a storage pool.

[rmmdiskgrp](#)

Use the **rmmdiskgrp** command to delete a storage pool without being able to recover it.

lsfreeextents

Use the **lsfreeextents** command to list the number of free extents that are available on a specified MDisk.

Syntax

➔ **lsfreeextents** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

mdisk_id / mdisk_name

(Required) Specifies the ID or the name of the MDisk for which you want to know the number of free extents.

Description

This command displays a count of the number of free extents on the specified MDisk.

An invocation example

```
lsfreeextents 2
```

The resulting output:

```
id 2
number_of_extents 4372
```

Related reference

[chmdiskgrp](#)

Use the **chmdiskgrp** command to modify the name that is assigned to a storage pool or to set the warning threshold for the storage pool. You can also change the ownership group.

lsmdiskgrp

Use the **lsmdiskgrp** command to display a concise list or a detailed view of storage pools that are visible to the system.

mkmdiskgrp

Use the **mkmdiskgrp** command to create a new storage pool.

rmmdisk

Use the **rmmdisk** command to delete a managed disk (MDisk) from a storage pool.

rmmdiskgrp

Use the **rmmdiskgrp** command to delete a storage pool without being able to recover it.

lsmdiskgrp

Use the **lsmdiskgrp** command to display a concise list or a detailed view of storage pools that are visible to the system.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are returned. If a capacity is specified, the units must also be included.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards when you use the command-line interface (CLI):

- The wildcard character is an asterisk (*).
- The command can contain a maximum of one wildcard, which must be the first or last character in the string.
- When you use a wildcard, you must enclose the filter entry within double quotation marks (" "), as shown in the following command:

```
lsmdiskgrp -filtervalue "name=md*"
```

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data is available to be displayed, headings are not displayed.

-bytes

(Optional) Specifies that you want the report to display all capacities as bytes.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The -

delim parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

object_id / object_name

(Optional) Specifies the name or ID of an object. When you use this parameter, the detailed view of the specific object is returned and any value that is specified by the **-filtervalue** parameter is ignored. If you do not specify the *object_id / object_name* parameter, the concise view of all objects that match the filtering requirements that are specified by the **-filtervalue** parameter are displayed.

-filtervalue?

(Optional) Displays a list of valid filter attributes. The valid filters for the **lsmdiskgrp** command are the following values:

- name
- id
- mdisk_count
- vdisk_count
- status
- storage_pool_id
- easy_tier
- easy_tier_status
- site_id
- site_name
- parent_mdisk_grp_id
- parent_mdisk_grp_name
- child_mdisk_grp_count
- type
- encrypt
- owner_type
- data_reduction

Description

This command returns a concise list or a detailed view of storage pools visible to the system.

Command output includes values for the following attributes:

status

The state of the MDisk with the highest-priority status in the group, excluding image mode MDisk.

VDisk_count

The number of volume copies that are in the storage pool.

capacity

The total amount of MDisk storage that is assigned to the storage pool.

extent_size

The sizes of the extents for this group are the following values: 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, or 8192 (MB).

free_capacity

The amount of MDisk storage that is immediately available. Additionally, *reclaimable_capacity* can eventually become available.

real_capacity

The total MDisk storage capacity assigned to volume copies.

Note: It includes `reclaimable_capacity`.

virtual_capacity

The total host mappable capacity of all volume copies in the storage pool.

used_capacity

The amount of data that is stored on MDisk. [standard-provisioned](#) volumes contribute their entire capacity.

Note: It includes `reclaimable_capacity`.

overallocation

Expressed as a percentage, the ratio of the `virtual_capacity` value to the capacity. A storage pool overallocation of over 100 is only possible if you configure thin-provisioned volume copies.

warning

This field is a percentage. A warning is generated when the amount of space in the storage pool that is assigned exceeds this level.

easy_tier

This value is set by the user and determines whether Easy Tier is permitted to manage the pool.

Note: The values are:

1. `on` indicates that Easy Tier actively manages the extents (including single-tier storage pools), and the Easy Tier status must be `active` - unless a license is required.
2. `off` indicates that Easy Tier does not actively manage the extents, and the Easy Tier status must be `inactive`.
3. `auto` indicates that the value of Easy Tier status is determined by the number of tiers in a storage pool.

Note: The following values apply to `auto`:

- `on` if Easy Tier is licensed or no license is required.
 - `off` if Easy Tier requires a license and none exists.
4. `measure` indicates that Easy Tier s collects statistics on that storage pool but does not move any extents in the storage pool.

easy_tier_status

This field indicates whether the Easy Tier functions are active on a storage pool.

- `active` indicates that a pool is being managed by Easy Tier to provide tier management performance-based pool balancing (for example, extents can be moved).
- `inactive` indicates that Easy Tier is inactive.
- `measured` indicates that Easy Tier statistics are being collected but no Easy Tier management is detected.
- `balanced` indicates that a pool is being managed by Easy Tier to provide performance-based pool balancing (for example, extents can be moved).

The following table describes the storage pool Easy Tier settings.

Table 124. Easy Tier settings for storage pools and volumes			
Storage pool Easy Tier setting	Number of tiers in the storage pool	Volume copy Easy Tier setting	Volume copy Easy Tier status
Off	One	Off	inactive (see note “1” on page 1446)
Off	One	On	inactive (see note “1” on page 1446)
Off	Two	Off	inactive (see note “1” on page 1446)

Table 124. Easy Tier settings for storage pools and volumes (continued)

Storage pool Easy Tier setting	Number of tiers in the storage pool	Volume copy Easy Tier setting	Volume copy Easy Tier status
Off	Two	On	inactive (see note “1” on page 1446)
Measure	One	Off	measured (see note “2” on page 1446)
Measure	One	On	measured (see note “2” on page 1446)
Measure	Two	Off	measured (see note “2” on page 1446)
Measure	Two	On	measured (see note “2” on page 1446)
Auto	One	Off	measured (see note “2” on page 1446)
Auto	One	On	balanced (see note “3” on page 1446)
Auto	Two	Off	measured (see note “2” on page 1446)
Auto	Two	On	active (see note “4” on page 1446)
On	One	Off	balanced (see note “3” on page 1446)
On	One	On	balanced (see note “3” on page 1446)
On	Two	Off	measured (see note “2” on page 1446)
On	Two	On	active (see note “4” on page 1446)

Notes:

1. When the volume copy status is inactive, no Easy Tier functions are enabled for that volume copy.
2. When the volume copy status is measured, the Easy Tier function collects usage statistics for the volume but automatic data placement is not active.
3. When the volume copy status is balanced, the Easy Tier function enables performance-based pool balancing for that volume copy.
4. When the volume copy status is active, the Easy Tier function operates in automatic data placement mode for that volume.

If the volume copy is in image or sequential mode or is being migrated, the volume copy Easy Tier status is measured instead of active.

The default Easy Tier setting for a storage pool is auto, and the default Easy Tier setting for a volume copy is on. Thus, Easy Tier functions except pool performance balancing are disabled for storage pools with a single tier, and that automatic data placement mode is enabled for all striped volume copies in a storage pool with two or more tiers.

tier

Indicates which tier information is being reported. The values are:

- tier0_flash
- tier1_flash
- tier_enterprise
- tier_nearline
- tier_scm

tier_mdisk_count

Indicates the number of MDisk in the tier.

tier_capacity

The amount of MDisk storage in this tier that is assigned to the storage pool.

tier_free_capacity

The amount of MDisk storage in this tier that has not been assigned.

compression_active

Indicates whether any compressed volume copies are in the storage pool. This field is blank for storage pools that are data reduction pools.

compression_virtual_capacity

Indicates the total provisioned (virtual) capacity for all compressed volume copies in regular storage pools. This field reports 0.00MB for data reduction pools.

compression_compressed_capacity

Indicates the total used capacity for all compressed volume copies in regular storage pools. This field reports 0.00MB for data reduction pools.

compression_uncompressed_capacity

Indicates the total uncompressed used capacity for all compressed volume copies in regular storage pools. This field reports 0.00MB for data reduction pools.

site_id

Indicates the site value for the storage pool group. This numeric value is 1, 2, 3, or blank.

site_name

Indicates the site name for the storage pool. This value is an alphanumeric value or is blank.

parent_mdisk_grp_id

Indicates the storage pool group ID. This value is a numeric string (in the range 0 - 127 characters) or blank.

parent_mdisk_grp_name

Indicates the storage pool group name. This value is an alphanumeric string (in the range 1 - 63 characters) or blank.

child_mdisk_grp_count

Indicates the number of child pools in the parent pools. This value is a numeric string (in the range 0 - 127 characters) or blank.

child_mdisk_grp_capacity

Indicates the total amount of space that is reserved for child pools.

type

Indicates the MDisk group type. The values are parent and child_thick.

encrypt

Indicates whether the data that is stored on the MDisk group is encrypted or not encrypted. The values are:

- yes if the pool has an encryption key.
- yes if the pool does not have an encryption key (and the pool contains MDisk and all are encrypted).
- no if the pool does not have an encryption key (and the pool contains MDisk and at least one is not encrypted).
- Blank if the pool does not have an encryption key (and the pool has no MDisk).

The following define the status fields, from lowest to highest priority:

Online

Indicates that the storage pool is online and available.

Offline

Indicates that all paths to the storage pool are lost.

owner_type

Indicates the type of owning object, such as a file system or application. This attribute is an alphanumeric string up to 20 characters in length.

data_reduction

Indicates that the storage pool is a data reduction pool. The values are yes or no.

physical_capacity

Indicates the total physical capacity of MDisk that belong to this storage pool. For any disks that do not display their physical capacity, displays the logical capacity value. The value must be a number (indicated in units) that is rounded to two decimal places.

physical_free_capacity

Indicates the total free physical capacity of MDisk that belong to this storage pool. For any disks that do not display their physical capacity, displays the logical capacity value. The value must be a number (indicated in units) that is rounded to two decimal places.

shared_resources

Indicates that one or more MDisk in this storage pool shares a resource provisioning group with an MDisk in another storage pool. It indicates cross contamination over-provisioning of physical resources between the storage pools. The value must be yes or no.

reclaimable_capacity

The approximate amount of storage in a data reduction pool that the system can eventually make available.

used_capacity_before_reduction

The data that is stored on non-[standard-provisioned](#) volume copies in a data reduction pool. It indicates the capacity before compression and deduplication.

used_capacity_after_reduction

The data that is stored on MDisk for non-[standard-provisioned](#) volume copies in a data reduction pool. It indicates the capacity after compression and deduplication.

deduplication_capacity_saving

The capacity that is saved by deduplication before compression in a data reduction pool.

overhead_capacity

The MDisk capacity that is reserved for internal usage.

compression_opportunity

The total capacity of all compressed volume copies in a data reduction pool.

Note: It excludes `deduplication_capacity_saving`.

deduplication_opportunity

The total **used_capacity_before_reduction** of all volume copies in a data reduction pool that are data deduplication enabled.

owner_id

Displays the ID of the ownership group.

owner_name

Displays the name of the ownership group.

vdisk_protection_enabled

Indicates if this pool has volume protection enabled. This field is combined with the system setting **vdisk_protection_enabled** to determine the pool **vdisk_protection_status**. The value is either yes or no.

vdisk_protection_status

Indicates whether volume protection is active for this pool. Volumes with one or more copies in a pool where **vdisk_protection_status** is active are protected. Volumes with all copies in pools with an inactive volume protection status are not protected volumes. This field depends on the system setting for **vdisk_protection_enabled** and the pool setting for **vdisk_protection_enabled**. It is active only when the storage pool has **vdisk_protection_enabled** set to yes and the system setting has **vdisk_protection_enabled** set to yes. Otherwise, it is inactive.

easy_tier_fcm_over_allocation_max

Displays the maximum over allocation which Easy Tier can migrate onto FlashCore Module arrays, when the array is used as the top tier in a multitier pool. The value acts as a multiplier of the physically available space. This value is a percentage or blank for unsupported products.

A concise invocation example

```
lsmdiskgrp -delim :
```

The following concise output is displayed:

Use the **chmdiskgrp** command to modify the name that is assigned to a storage pool or to set the warning threshold for the storage pool. You can also change the ownership group.

[lsfreeextents](#)

Use the **lsfreeextents** command to list the number of free extents that are available on a specified MDisk.

[mkmdiskgrp](#)

Use the **mkmdiskgrp** command to create a new storage pool.

[rmmdisk](#)

Use the **rmmdisk** command to delete a managed disk (MDisk) from a storage pool.

[rmmdiskgrp](#)

Use the **rmmdiskgrp** command to delete a storage pool without being able to recover it.

mkmdiskgrp

Use the **mkmdiskgrp** command to create a new storage pool.

Syntax

Parameters

-name *pool_name*

(Optional) Specifies a name to assign to the new pool.

-mdisk *mdisk_id_list* | *mdisk_name_list*

(Optional) Specifies a colon-separated list of managed disk IDs or names to add to the storage pool. You can create an empty storage pool by not specifying the **-mdisk** parameter.

-tier *tier0_flash* | *tier1_flash* | *tier_enterprise* | *tier_nearline* | *tier_scm*

(Optional) Specifies the tier of the MDisk or MDiskS being added.

tier0_flash

Specifies a **tier0_flash** hard disk drive or an external MDisk for the newly discovered or external volume.

tier1_flash

Specifies an **tier1_flash** (or flash drive) hard disk drive or an external MDisk for the newly discovered or external volume.

tier_enterprise

Specifies a **tier_enterprise** hard disk drive or an external MDisk for the newly discovered or external volume.

tier_nearline

Specifies a **tier_nearline** hard disk drive or an external MDisk for the newly discovered or external volume.

tier_scm

Specifies a **tier_scm** hard disk drive or an external MDisk for the newly discovered or external volume.

If you do not specify a tier, the current tier value of the MDisk is retained. The default value for an external MDisk is *enterprise*.

Note: Since Release 8.1.0, the tier of MDiskS mapped from certain types of IBM System Storage Enterprise Flash is fixed to **tier0_flash**, and cannot be changed.

-ext *extent_size*

(Required) Specifies the size of the extents for this group in MB. The **ext** parameter must have one of the following values: 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, or 8192 (MB). [Data reduction pools do not support a value of less than 1024. If you enter a value that is less than 1024, the command rounds it up to 1024.](#)

-size *mdiskgrp_size*

(Optional) Specifies the child pool capacity. The value must be a numeric value (and an integer multiple of the extent size).

-parentmdiskgrp *mdiskgrp_id* | *mdiskgrp_name*

(Optional) Specifies the parent pool from which the volume extents of the child pool are allocated when you create a child pool. The value must be an *mdiskgrp_id* or *mdiskgrp_name*.

-warning *disk_size* | *disk_size_percentage*

(Optional) Generates a warning when the used disk capacity in the storage pool first exceeds the specified threshold. You can specify a *disk_size* integer, which defaults to megabytes (MB) unless the **-unit** parameter is specified; or you can specify a *disk_size%*, which is a percentage of the storage pool size. To disable warnings, specify 0 or 0%. The default value is 0.

-unit *b* | *kb* | *mb* | *gb* | *tb* | *pb*

(Optional) Specifies the data units for the **-warning** parameter.

-easytier *on* | *off* | *auto* | *measure*

(Optional) Specifies if the Easy Tier function is active for this storage pool, or if it is automatically determined. *auto* is the default value. **-easytier** is active in storage pools with multiple tiers and is balance with single tiers.

Note:

- If **-easytier** is set to *auto*, the system automatically enables Easy Tier functions when the storage pool contains MDisk from more than one tier, and enables automatic rebalancing when the storage pool contains an MDisk from only one tier.
- If **-easytier** is set to *on*, then Easy Tier functions are active.
- If **-easytier** is set to *off*, then Easy Tier functions are inactive.
- If **-easytier** is set to *measure* Easy Tier statistics are collected but Easy Tier management is disabled. (No extents are moved by Easy Tier).

auto equates to:

- *on* if Easy Tier is licensed or no license is required.
- *off* if Easy Tier is not licensed and a license is required.

Specifying **-easytier on** enables Easy Tier:

- Management of both single-tier and multitier pools
- Auto rebalance

Extents are moved to balance the I/O load on the MDisk in the pool.

-owner owner_type

(Optional) Specifies the owner type. The value must be *vvol_child_pool*.

-encrypt yes / no

(Optional) Specifies the encryption status for this storage pool. The values are *yes* or *no*.

Remember:

- If you do not specify **-encrypt** and encryption is enabled, the system defaults to **-encrypt yes** (the default encryption setting).
- When you create a child pool in an encrypted parent pool, the value must not be *no*. (All other permutations are permitted).

-datareduction yes / no

(Optional) Specifies whether the storage pool is a data reduction storage pool. The values are *yes* or *no*. A value of *no* specifies that the storage pool is a standard storage pool.

-ownershipgroup owner_id / owner_name

(Optional) The name or ID of the ownership group to which the object is being added.

-etfcmoverallocationmax percentage / off

(Optional) Sets the maximum over allocation which Easy Tier can migrate onto FlashCore Module arrays, when the array is used as the top tier in a multitier pool. The value acts as a multiplier of the physically available space. The allowed values are a percentage in the range of 100% (default) to 400% or **off**. Setting the value to **off** disables this feature.

-vdiskprotectionenabled yes / no

(Optional) Specifies whether volume protection is enabled for this storage pool. The default value is **yes**, except for child pools where the default value is inherited from the parent pool.

Description

Table 125. Parameter differences for child pools and storage pools		
Parameter	Child pool usage	Storage pool usage
-name	Optional	Optional for both parent pools and child pools.
-mdisk	Cannot be used with child pools.	Optional
-tier	Cannot be used with child pools.	Optional
-easytier	Cannot be used with child pools.	Optional

Table 125. Parameter differences for child pools and storage pools (continued)

Parameter	Child pool usage	Storage pool usage
-size	Mandatory	Cannot be used with parent pools.
-parentmdiskgrp	Mandatory	Cannot be used with parent pools.
-ext	Cannot be used for child pools.	Mandatory
-unit	Optional	Optional for both parent pools and child pools.
-warning	Optional	Optional for both parent pools and child pools.
-encrypt	Optional	Optional for both parent pools and child pools.
-datareduction	Cannot be used with - parentmdiskgrp Note: A child pool cannot be created from a data reduction pool.	Data reduction pools must be a parent pool.

The **mkmdiskgrp** command creates a new storage pool and assigns the storage pool name if specified. The ID of the new storage pool is returned if the command is successful. Storage pools are collections of managed disks. Each storage pool is divided into chunks, called extents, which are used to create volumes.

Optionally, you can specify a list of managed disks that are added to this storage pool. These managed disks cannot belong to another storage pool, and they must have a mode of unmanaged. Use the **lsmdiskcandidate** command to get a list of suitable candidates. If **-tier** is specified, it applies to all of the MDisk.

Each managed disk that is a member of this group is split into extents. The storage that is available on these disks is added to a pool of extents that is available in this group. When a volume is created from this group, free extents from the pool are used, in accordance with the policy used when the volume was first created.

Subsequently, all managed disks added to this group are split into extents of the same size as the size that is assigned to the group.

When you choose an extent size, be aware of the amount of storage you want to virtualize in this group. The system maintains a mapping of extents between volumes and managed disks. The system can only manage a finite number of extents (4 194 304). One system can virtualize the following number of extents:

- 64 TB - if all storage pools have extent sizes of 16 MB.
- 2 PB - if all storage pools have extent sizes of 512 MB.
- 32 PB - if all storage pools have extent sizes of 8192 MB.

Important: The extent size for the storage pool can also limit volume size. Consider the maximum volume size that you want to use when you create storage pools. Refer to the information on creating storage pools for a comparison of the maximum volume capacity for each extent size. The maximum is different for thin-provisioned volumes.

Note: When an image mode volume is created, the storage pool increases in capacity by the size of the image mode volume (not the MDisk capacity) because the image mode volume might be smaller than the MDisk itself. If an extent is migrated from the image mode volume or MDisk to elsewhere in the group, the volume becomes a striped volume (no longer image mode). At this point, the available capacity might

increase because the extra capacity available on the MDisk (for example, the capacity that was not part of the image mode volume) becomes available.

When you specify `-name pool_name` if you do not also specify **-parentmdiskgrp**, you create a parent pool where `pool_name` is the name of the new storage pool. When you specify `-name pool_name`, if you also specify **-parentmdiskgrp** and a size for it, you create a child pool where `pool_name` is the name of the new storage pool.

Note:

A data reduction pool is created by using the **-datareduction** parameter set to yes. The pool can be used to create [standard-provisioned](#), thin or compressed volumes, or volume copies.

There is a maximum number of four data reduction pools in a system. When this limit is reached, creating any further pools with **-datareduction** set to yes is not possible.

The **-datareduction** parameter cannot be used to create a child pool. Creating a child pool whose parent is already a data reduction pool is not allowed.

In most cases volume protection is applied on a volume level, but a volume might have more than one copy, with copies in different storage pools, which in turn can have different protection settings. A volume is protected when it has one or more copies in a storage pool that has `vdisk_protection_status` active.

For **rmvdiskcopy**, volume protection is applied on a volume copy level, but only when you delete the last volume copy. When you delete one of two volume copies, volume protection is not applied. It means that a volume copy might be deleted from a protected storage pool and leaves a remaining copy in an unprotected storage pool that might then later be deleted without volume protection checks.

An invocation example

This example adds a list of MDisk to the storage pool.

```
mkmdiskgrp -mdisk mdisk0:mdisk1:mdisk2:mdisk3 -ext 32
```

The resulting output:

```
MDisk Group, id [0], successfully created
```

An invocation example

This example specifies tier and Easy Tier information when you add a list of MDisk to the storage pool.

```
mkmdiskgrp -mdisk mdisk13:mdisk16 -ext 512 -tier tier_nearline -easytier measure
```

The resulting output:

```
MDisk Group, id [13], successfully created
```

An invocation example

This example creates a child pool from a parent pool.

```
mkmdiskgrp -size 100 -unit tb -parentmdiskgrp phypool
```

The resulting output:

```
MDisk Group, id [3], successfully created
```

An invocation example

This example creates a child pool from a parent pool and specifies an owner type.

```
mkmdiskgrp -parentmdiskgrp p0 -size 100 -unit gb -owner vvol_child_pool
```

The resulting output:

```
MDisk Group, id [3], successfully created
```

An invocation example

This example creates an encrypted child pool from a parent pool.

```
mkmdiskgrp -parentmdiskgrp 2 -name _my_encrypted_child_pool -encrypt yes -size 10 -unit gb
```

The resulting output:

```
MDisk Group, id [5], successfully created
```

An invocation example

This example creates an empty data reduction pool.

```
mkmdiskgrp -ext 512 -datareduction yes
```

The resulting output:

```
MDisk Group, id [16], successfully created
```

An invocation example

This example creates a data reduction pool with MDisk.

```
mkmdiskgrp -ext 512 -mdisk 3:5:6 -datareduction yes
```

The resulting output:

```
MDisk Group, id [17], successfully created
```

An invocation example

This example creates a protected storage pool with MDisk.

```
mkmdiskgrp -ext 512 -mdisk 8:9:10 -vdiskprotectionenabled yes
```

The resulting output:

```
MDisk Group, id [18], successfully created
```

rmmdisk

Use the **rmmdisk** command to delete a managed disk (MDisk) from a storage pool.

rmmdiskgrp

Use the **rmmdiskgrp** command to delete a storage pool without being able to recover it.

rmmdisk

Use the **rmmdisk** command to delete a managed disk (MDisk) from a storage pool.

Syntax

Parameters

-mdisk mdisk_id_list / mdisk_name_list

(Required) Specifies one or more managed disk IDs or names to delete from the group.

-force

(Optional) Migrates data on the specified disks to other disks in the group. The command completes asynchronously if **-force** is specified.

mdisk_group_id / mdisk_group_name

(Required) Specifies the ID or name of the storage pool to delete the disks from. The warning threshold for a storage pool is automatically scaled when MDisks are deleted.

Description

This command attempts to remove the managed disk or disks from the group.

Remember: This command cannot be used for child pools.

Deleting a managed disk from a group can be done only if the managed disk does not contain any extents in use by a volume. If there are extents in use and you do not supply the force flag, the command fails.

Attention: If this disk being removed has already been powered down, removed, or is experiencing a power outage, the migration is pending and does not complete until the MDisk comes back online. The MDisk is not removed from the list of MDisks that are contained in the group.

If the disk has been deliberately removed, the only method of removing the MDisk is to remove the entire group itself.

Ensure that you do not destroy any controller LUNs until you delete them from the storage pool that they belong to.

The **rmmdisk** command fails if there are insufficient free extents on other disks in the storage pool for the duration of the command.

If you do specify the force flag, an attempt is made to migrate the extents that are in use onto other free extents within the storage pool. If there are not enough free extents in the storage pool, the command will fail even if the force flag is specified.

When an array MDisk is in a storage pool, five extents in the storage pool are reserved for internal use. If you attempt to remove an MDisk when an array MDisk is in the storage pool, the command fails (even if the **-force** flag is specified), if five free extents do not remain in the storage pool.

To delete the disks from the group, you have the following options:

- You can delete the volume that is using the extents that are specified on the managed disk.
- You can add more managed disks to the group, rerun the command and specify the **-force** parameter.

When data is being migrated from the managed disk, it might take some time for the command to complete. The command itself returns with a success code, notifying you that migration is in progress (if migration is required). An event is logged when the migration is complete and the disk is deleted from the group at this time. You can also check the progress of any active migrations by running the **lsmigrate** command.

If you specify **-force**, the **rmmdisk** command fails if there are offline MDisks. If there are no online quorum disks the migration fails.

Remember: When using the **-mdisk** parameter, MDisks are removed if there is one (or more) SAS MDisk specified in the list.

An invocation example

```
rmmdisk -mdisk mdisk12 -force Group3
```

The resulting output:

```
No feedback
```

[rmmdiskgrp](#)

Use the **rmmdiskgrp** command to delete a storage pool without being able to recover it.

rmmdiskgrp

Use the **rmmdiskgrp** command to delete a storage pool without being able to recover it.

Syntax

```
➔ rmmdiskgrp                      mdisk_group_id                     
                    -force                    mdisk_group_name
```

Parameters

-force

(Optional) Specifies that all volumes and host mappings be deleted. When you use this parameter, all managed disks in the storage pool are removed and the storage pool itself is deleted.

Remember:

- You must specify **-force** to delete a child pool if it contains volume.
- You cannot specify **-force** to delete a parent pool if it has child pools.

Note: The command fails if **-force** is used to delete an MDisk group if:

- Any of the VDisks in the MDisk group are mirrored across multiple MDisk groups (other than the one that is being deleted).
- AND any of the VDisk mirrors are out of sync.
- AND an attempt is made to delete the in-sync copy. Deleting the only in-sync copy requires **-force**. Otherwise, it isn't needed if the VDisk has another in-sync copy.
- AND the out-of-sync copy is a thin-provisioned or compressed copy in a data reduction pool.

Note: When you use the **-force** parameter to delete a storage pool that has volume protection inactive but includes mirrored volumes with out-of-sync copies in a storage pool with volume protection active, then volume protection applies to these volumes. The out-of-sync copies are deleted from the storage pool with volume protection active as part of the forced delete. The command fails if host I/O is being sent to these mirrored volumes in the defined volume protection time period.

mdisk_group_id | mdisk_group_name

(Required) Specifies the ID or name of the storage pool that is to be deleted.

Note: You cannot delete a parent pool that has child pools. You must first delete the child pools.

Description

Important: Before you issue the command, ensure that you want to delete all mapping information. Data that is contained on the volume cannot be recovered after the storage pool is deleted.

The `immddiskgrp` command deletes the specified storage pool. The **-force** parameter is required if there are volumes that have been created from this storage pool or if there are managed disks in the storage pool. Otherwise, the command fails.

Note: This command also removes any associated storage pool throttling.

Deleting a storage pool is essentially the same as deleting a system or part of a system because the storage pool is the central point of control of virtualization. Because volumes are created by using available extents in the storage pool, mapping between volume extents and managed disk extents is controlled based on the storage pool.

The command deletes all volume copies in the specified storage pool. If the volume has no remaining synchronized copies in other storage pools, the volume is also deleted.

This command deletes the associated MDisk group (storage pool) throttle if that storage pool is removed.

Remember: This command is unsuccessful if:

- Volume protection is enabled (by using the **chsystem** command).
- The MDisk being removed is mapped to any volume that received I/O within the defined volume protection time period.

Remember: This command partially completes asynchronously. All volumes, host mappings, and Copy Services relationships are deleted before the command completes. The deletion of the storage pool then completes asynchronously.

In detail, if you specify the **-force** parameter and the volumes are still using extents in this storage pool, the following actions are initiated or occur:

- The mappings between that disk and any host objects and the associated Copy Services relationships are deleted.
- If the volume is a part of a FlashCopy mapping, the mapping is deleted.

Note: If the mapping is not in the `idle_or_copied` or `stopped` states, the mapping is force-stopped and then deleted. Force-stopping the mapping might cause other FlashCopy mappings in the system to also be stopped. For more information, see the description for the **-force** parameter in the **stopfcmap** command.

- Any volume that is in the process of being migrated into or out of the storage pool is deleted. It frees up any extents that the volume was using in another storage pool.
- Volumes are deleted without first flushing the cache. Therefore, the storage controller LUNs that underlie any image mode MDisk might not contain the same data as the image mode volume before the deletion.
- If managed disks exist in the storage pool, all disks are deleted from the storage pool. They are returned to the unmanaged state.
- The storage pool is deleted.

Attention: If you use the **-force** parameter to delete all the storage pools in your system, you are returned to the processing state where you were after you added nodes to the system. All data that is contained on the volumes is lost and cannot be recovered.

An invocation example

```
rmmdiskgrp -force Group3
```

The resulting output:

```
No feedback
```

Chapter 29. User management and access control commands

Use the user management and access control commands to configure remote authentication service, access control, and manage users and groups on the system.

chauthservice

Use the **chauthservice** command to configure the remote authentication service of the system.

Syntax

Parameters

-enable yes | no

(Optional) Enables or disables the system's use of the remote authentication server. When the **enable** parameter is set to no, remote authentications are failed by the system, but local authentications continue to operate normally.

-type ldap

(Optional) Specifies the authentication service type (which must be LDAP). An LDAP server must be configured.

Remember: The remote authentication service must be enabled (**-enable yes**) for this setting to come into effect.

-url url

(Optional - IBM Security Services only) Specifies the website address (URL) of Security Services, which is referred to as TIP in the CLI. The host part of the URL must be a valid numeric IPv4 or IPv6 network address. You can use the following characters in the URL:

- a - z
- A - Z
- 0 - 9
- -
- ~
- :
- [
-]

- %
- /

The maximum length of the URL is 100 characters.

This option is no longer used.

-username *user_name*

(Optional) Specifies the HTTP basic authentication user name. The user name cannot start or end with a blank. The user name can consist of a string of 1 - 64 ASCII characters except for the following characters:

- %
- :
- "
- ,
- *
- '

-password '*password*'

(Optional) Specifies the HTTP basic authentication user password. The password cannot start or end with a blank. It must consist of a string of 6 - 64 printable ASCII characters. [You must enclose the password in single quotation marks.](#) The *password* variable is optional. If you do not provide a password, the system prompts you and does not display the password that you type. [Do not enclose the password in single quotation marks if you use the prompt.](#)

-sslcert *file_name*

(Optional) Specifies the name of the file that contains the SSL certificate, in privacy enhanced mail (PEM) format, for the remote authentication server. The certificate file must be in valid PEM format and have a maximum length of 12 KB.

-refresh

(Optional) Causes the system to invalidate any remote user authorizations that are cached on the system. Use this option when you modify user groups on the authentication service and want the change to immediately take effect on the system.

Note: If you clear the cache, anyone who uses the system might have to log in again (for example, if credentials are provided to one of the defined LDAP servers).

Description

The system authenticates remote users by using Lightweight Directory Access Protocol (LDAP).

Before you enable remote authentication, ensure that the properties of the service are properly configured on the system. It is not necessary to disable the remote authentication service to change its properties. LDAP authentication can be configured by using the **chldap** command, and LDAP servers can be added to the system by using the **mkldapserver** command.

Remember: For the authentication type to be set to LDAP with authorization enabled (true), an LDAP server must be configured.

When the authentication service is enabled, the system does not test whether the remote authentication system is operating correctly.

- To establish whether the system is operating correctly, enter the **lscurrentuser** command for a remotely authenticated user. If the output lists the user roles that are obtained from the remote authentication server, remote authentication is operating successfully. If the output is an error message, remote authentication is not working correctly, and the error message describes the problem.
- To establish whether LDAP is operating correctly, in addition to the **lscurrentuser** command, enter the **testldapserver** command. The **testldapserver** command can be entered whether or not remote authentication is enabled, and can be used to test the connection to LDAP servers, as well as user authorization and authentication.

To disable the remote authentication service in a controlled manner when it is not available, use the **enable** parameter with the no option.

An invocation example

To disable remote authentication, enter the following command:

```
chauthservice -enable no
```

The following text is displayed when the command runs:

```
No feedback
```

An invocation example

To refresh the system remote authorization cache, enter the following command:

```
chauthservice -refresh
```

The following text is displayed when the command runs:

```
No feedback
```

Use the **rmuser** command to delete a user.

rmusergrp

Use the **rmusergrp** command to delete a user group.

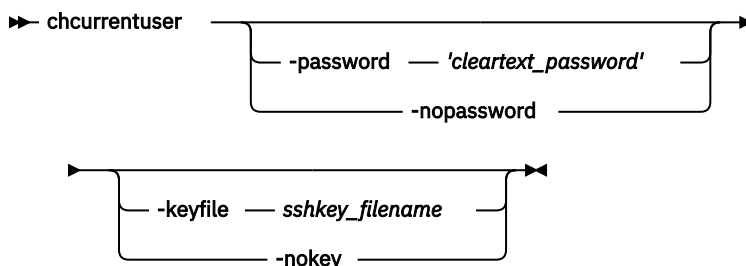

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

chcurrentuser

Use the **chcurrentuser** command to change the attributes of the current user.

Syntax

Parameters

-password 'cleartext_password'

(Optional) Specifies the new password to be associated with the current user. The password cannot start or end with a blank. It must consist of a string of 6 - 64 printable ASCII characters. **You must enclose the password in single quotation marks.** You can optionally specify the password with the **-password** parameter. If you do not specify the password, the system prompts you for it before running the command and does not display the password that you type. **Do not enclose the password in single quotation marks if you use the prompt.** Either the **-password** parameter or the **-nopassword** parameter can be set.

-nopassword

(Optional) Specifies that the user's password is to be deleted.

-keyfile *sshkey_filename*

(Optional) Specifies the name of the file that contains the Secure Shell (SSH) public key. Either the **keyfile** parameter or the **nokey** parameter can be set.

-nokey

(Optional) Specifies that the user's SSH key is to be deleted.

Description

Use the **chcurrentuser** command to modify the attributes of the current user.

An invocation example

```
chcurrentuser -password 'secret' -nokey
```

The resulting output:

```
No feedback
```

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

chldap

Use the **chldap** command to change system-wide Lightweight Directory Access Protocol (LDAP) configuration. This command can be used to configure remote authentication with LDAP. These settings apply when authenticating against any of the LDAP servers configured using the **mkldapserver** command.

Syntax

Parameters

-type *ad* | *itds* | *other* | **-reset**

(Optional) Specify the LDAP server type, or reset LDAP configuration to defaults for the current server type. Defaults for the configured server type:

- Active Directory (AD)
- IBM Security Directory Server (ISDS)
- Other

-username *username*

(Optional) Specifies a username for administrative binding. This can be:

Note:

- A distinguished name (DN)
- A user principal name (UPN) or NT login name for Active Directory

-password *password*

(Optional) Specifies the password for the administrative binding. You can optionally specify the password with this parameter. **You must enclose the password in single quotation marks.** If you do not specify the password, the system prompts you for it before running the command and does not display the password that you type. **Do not enclose the password in single quotation marks if you use the prompt.**

-encpassword *password*

(Optional) Specifies the password for the enclosure. You can optionally specify the password with this parameter. **You must enclose the password in single quotation marks.** If you do not specify the password, the system prompts you for it before running the command and does not display the password that you type. **Do not enclose the password in single quotation marks if you use the prompt.**

-security *tls / ssl / none*

(Optional) Specifies the type of security to use when communicating with LDAP servers. Specifying **tls** enables Transport Layer Security (TLS) security. Specifying **ssl** enables Secure Socket Layer (SSL) security. The default value is **none**.

-userattribute *user_attribute*

(Optional) Specifies the LDAP attribute used to determine the user name of remote users. The user attribute must exist in your LDAP schema and must be unique for each of your users.

-groupattribute *group_attribute*

(Optional) Specifies the LDAP attribute used to determine the group memberships of remote users. The attribute must contain either the DN of a group or a colon-separated list of group names.

-auditlogattribute *auditlogattribute*

(Optional) Specifies the LDAP attribute used to determine the identity of remote users. When a user performs an audited action, this information is recorded in the audit.

-authcacheminutes *auth_cache_minutes*

(Optional) Specifies the period for which to cache authentication details.

-nestedgroupsearch *client / server / off*

(Optional) Specifies whether nested groups are evaluated on the client (clustered system), server (authentication service), or are not evaluated not at all.

Description

At least one parameter must be specified.

The **chldap** command can be run whether or not LDAP authentication is enabled. Specifying **-reset** or **-type** populates the default values unless otherwise specified.

You can only specify **-password** or **-encpassword** if **-username** is specified.

The **-type** parameter values are only set to defaults for the specified type if the type is different from the existing type.

If the type is **itds**, **-nestedgroupsearch** cannot be executed (nested groups are evaluated by default). If the type is **ad**, **-nestedgroupsearch** can only be set to **client** or **off** because there is no server support. If the type is **other**, the **-nestedgroupsearch** parameter is fully configurable.

Use **-username** to specify a distinguished name (DN), user principal name (UPN), or NT login name. Distinguished names (DN) must be a sequence of attribute=value pairs separated by a comma (,), semicolon (;), or plus sign (+). A backslash (\) must be used to escape special characters, and can also be used to specify UTF-8 characters using their byte encoding. For example, c acute can be represented as \C4\87. NT logins are valid for only the Active Directory and must be in the DOMAIN\user format. These logins must not start or end with a period (.) and both the DOMAIN and the user must not use the following characters: \ / : ? " < > | UPN logins are valid for Active Directory only and must be in the format user@suffix. Both user and suffix can not use spaces or the following characters: () < > , ; : \ " [] @

Tip:

- Remember that **-userattribute**, **-groupattribute**, and **-auditlogattribute** accept values that:

1. Must begin with a letter
2. Only contain ASCII letters, digit characters, and hyphens
3. Are case-insensitive

The following LDAP (first-time) configuration suggestions assist with LDAP server setup:

Important:

- Ensure that the system is configured appropriately according to your LDAP schema. Issue **chldap -type** to populate the system's LDAP configuration with the server type defaults. Issue **chldap -reset** to return to these defaults at any time.
 - (Advanced) For all server types, users are authenticated with a username configured in the LDAP attribute `user_attribute`. This attribute must exist in the LDAP schema and must be unique for each user. It is configurable by issuing **chldap -userattribute**. Active Directory users can also authenticate using their UPN or NT login names.
 - (Advanced) Authenticated users are assigned roles according to their LDAP group memberships. Each user's group memberships must be stored in the LDAP attribute `group_attribute`. This can be either an LDAP attribute containing the DN of the user's LDAP group, or an LDAP attribute containing a colon-separated list of user group names. It is configurable by issuing **chldap -groupattribute**.
 - (Advanced) When an LDAP authenticated user runs a command that is audited, the user's login name is placed in the audit log. The name is extracted from the LDAP attribute `audit_log_attribute`, which is configurable by issuing **chldap -auditlogattribute**.
- Ensure that the system is able to search within the user and group trees on LDAP servers. By default the system authenticates anonymously. Consequently, you must either permit anonymous searches of the LDAP directory, or create an LDAP user with the appropriate permissions and issue the **chldap -username** and **chldap -password** commands to instruct the system to search as this user.
- Ensure that the system is able to connect with the appropriate level of security. Passwords are sent to the LDAP server as clear text, so Transport Layer Security (TLS) encryption is recommended. Issue **chldap -security** to change the security level.
- (Advanced): On Active Directory and some other LDAP servers, the system (by default) identifies groups to which users belong directly. To assign users permissions according to a parent group, enable the nested group search on the client by issuing **chldap -nestedgroupsearch**. This setting has an additional performance overhead and supports up to 8 levels of nesting.

An invocation example

```
chldap -type
itds -username uid=joebloggs,cn=admins,dc=company,dc=com -password 'passw0rd'
-auditlogattribute descriptiveName
```

The resulting output:

```
No feedback
```

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

chldapserver

Use the **chldapserver** command to modify a Lightweight Directory Access Protocol (LDAP) server.

Syntax

Parameters

-ip *ip_address*

(Optional) Specifies either a server IP address (Internet Protocol Version 4 or 6), or a fully-qualified domain name (FQDN) (maximum of 64 characters). (FQDN is not supported by 840 AE1.)

-name *server_name*

(Optional) Specifies the LDAP server name.

-port *port*

(Optional) Specifies the LDAP server port. The default value (if you do not specify a value) is 389. If you specify TLS security the value is 389 and if you specify SSL security the value is 636.

-sslcert *file_name* | -nsslcert

(Optional) Set (**-sslcert**) or clear (**-nsslcert**) the secure socket layer (SSL) certificate.

-basedn *base_dn* | -nobasedn

(Optional) Use the base distinguished name (DN) for search (**-nobasedn** indicates to use the default DN).

-preferred *yes / no*

(Optional) Specifies whether the server is preferred over other configured LDAP servers (or not preferred).

ldap_server_id* | *ldap_server_name

(Required) Specifies the LDAP server ID or name.

Description

Important: During normal operation, LDAP requests are sent to **-preferred** servers depending on availability. If no servers are marked as **-preferred**, LDAP requests are sent to configured servers based on availability.

If **-sslcert** is specified, the server certificate is verified while authenticating. The SSL certificate must exist on the current node. If **-nsslcert** is specified, any certificate file is deleted and the server certificate is not checked.

The **-basedn** parameter indicates the distinguished name (DN) to use as a base from which to search for users in the LDAP directory. If Transport Layer Security (TLS) is enabled and **-sslcrt** is specified, the server certificate is verified during authentication. The secure socket layer (SSL) certificate must exist on the node being used. Otherwise, a server certificate is not checked.

The system must be configured with an appropriate version IP address when **-ip** is specified. The IP address specified with the **-ip** parameter must be of a version supported by the system. The certificate file must be in valid PEM format and have a maximum length of 12 kilobytes.

Distinguished names must be a sequence of attribute=value pairs separated by a comma (,), semi-colon(;), or plus sign (+) escaping special characters with \ where appropriate, and specified UTF-8 characters using their byte encoding. For example, , for commas or \C4\87 for the UTF-8 character c acute.

This command runs whether or not LDAP authentication is enabled.

Remember: There can be a maximum of six configured LDAP servers. If you attempt to create a seventh LDAP server an error is returned.

An invocation example with basic server details

```
chldapserver -ip 192.135.60.3 -port 400 ldapserver0
```

The resulting output:

```
No feedback
```

An invocation example specifying an SSL certificate

```
chldapserver -sslcrt /tmp/activedirectorycert.pem 0
```

The resulting output:

```
No feedback
```

An invocation example to remove an SSL certificate

```
chldapserver -nsslcrt 0
```

The resulting output:

```
No feedback
```

Use the **lsldap** command to display the details for the system-wide Lightweight Directory Access Protocol (LDAP) configuration.

lsldapserver

Use the **lsldapserver** command to display the most recent details for all configured Lightweight Directory Access Protocol (LDAP) servers.

lsownershipgroup

The **lsownershipgroup** command displays the ownership groups that are available in the system.

lsuser

Use the **lsuser** command to display a list of the users that is created on the system.

lsusergrp

Use the **lsusergrp** command to display a list of the user groups that is created on the system.

mkldapserver

Use the **mkldapserver** command to display the data used to create a Lightweight Directory Access Protocol (LDAP) server.

mkownershipgroup

The **mkownershipgroup** command creates an ownership group.

mkuser

Use the **mkuser** command to create either a local or a remote user to access a system.

mkusergrp

Use the **mkusergrp** command to create a new user group.

rmlldapserver

Use the **rmlldapserver** command to delete a Lightweight Directory Access Protocol (LDAP) server.

rmownershipgroup

The **rmownershipgroup** command deletes an ownership group.

rmuser

Use the **rmuser** command to delete a user.

rmusergrp

Use the **rmusergrp** command to delete a user group.

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

chnaskey

The **chnaskey** command provides an interface to set or reset the Secure Shell (SSH) private and public key credential pair used by communications between the Storwize V7000 Unified file modules and the

control enclosure over the site 1 Gbps Ethernet LAN. This is required during the USB initialization of the Storwize V7000 Unified system.

Syntax

Parameters

-pubkeyfile filename | -privkeyfile filename | -reset

During the Universal Serial Bus (USB) initialization of the Storwize V7000 Unified system, one of the node canisters in the control enclosure creates a public/private key pair to use for Secure Shell (SSH). The node canister stores the public key and writes the private key to the USB flash drive memory.

One of the file modules then takes the private key from the USB flash drive memory to use for SSH. The file module passes it to the other file module over the direct connect Ethernet link and then deletes the private key from the USB flash drive memory so that it cannot be used on the wrong system.

Note:

- The **pubkeyfile** parameter must be an alphanumeric string up to 255 characters in length, and the file must be less than 2048 bytes.
- The **privkeyfile** must be an alphanumeric string up to 251 characters in length.

pubkeyfile provides an existing public keyfile in use. This does not generate anything, but replaces the currently used public key with another public key. The private key file on the file modules is used to generate the original public key file when it is set on the system.

privkeyfile generates the public and private key pair, and sets the public key on the system. It also provides the private key for installation on the file modules (in the /dumps directory or on the USB stick depending on what was used).

-reset

(Optional) Specifies that the public and private key pair should be cleared, and the system should be reset.

Description

It might be necessary to reset the Network Attached Storage (NAS) SSH key in the following circumstances:

- When communications between the Storwize V7000 Unified file module and the control enclosure are not authorized because of a bad key.
- When both Storwize V7000 Unified file modules have lost the original NAS SSH key.
- When the control enclosure has lost the NAS SSH key.

Resetting the NAS SSH key

Reset the NAS SSH key so that communications between the Storwize V7000 Unified file modules and the control enclosure resume.

1. Log on to the control enclosure management command-line interface (CLI) as `superuser` and run this command:

```
satask chnaskey -privkeyfile NAS.ppk
```

The private key is left in the /dumps directory.

2. Use SCP to copy the private key file to the Storwize V7000 Unified file module:

```
scp -P 1602 /dumps/NAS.ppk root@<file module management IP>:/files
```

You are prompted for the file module root password.

3. Log on to the management Command-Line Interface (CLI) as admin and run this command:

```
chstoragesystem --privkey/files
```

This command installs the new key.

rmuser

Use the **rmuser** command to delete a user.

rmusergrp

Use the **rmusergrp** command to delete a user group.

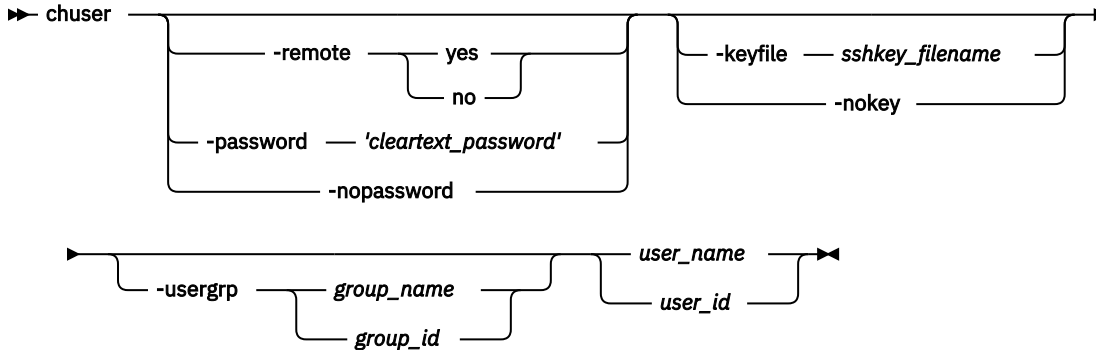

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

chuser

Use the **chuser** command to change the attributes of an existing user.

Syntax

Parameters

-remote yes | no

(Optional) Specifies whether the user authenticates to the cluster by using a remote authentication service. Either yes or no must be set. **If a password is already set, you cannot specify -remote yes.**

-password cleartext_password

(Optional) Specifies the new password to be associated with the user. **This parameter fails if remote is already set.** The password cannot start or end with a blank. It must consist of a string of 6 - 64 printable ASCII characters. **You must enclose the password in single quotation marks.** You can optionally specify the password with the **-password** parameter. If you do not specify the password, the system prompts you for it before running the command and does not display the password that you type. **Do not enclose the password in single quotation marks if you use the prompt.** Either the **-password** parameter or the **-nopassword** parameter can be set.

-nopassword

(Optional) Specifies that the user's password is to be deleted.

-keyfile sshkey_filename

(Optional) Specifies the name of the file that contains the Secure Shell (SSH) public key. Either the **keyfile** parameter or the **nokey** parameter can be set.

-nokey

(Optional) Specifies that the user's SSH key is to be deleted.

-usergrp group_name | group_id

(Optional) Specifies the new group for the user.

user_name | user_id

(Required) Specifies the user whose attributes are to be changed.

Description

Use the **chuser** command to modify the attributes of an existing user.

You must have the Security Administrator role to create, delete, or change a user. You can issue all commands except for **sainfo** and **satask** commands. These commands can only be issued by user superuser.

Only use the **usergrp** parameter for local users. If you change a user from local to remote, the user's association with any group is removed.

If you change a user from remote to local, a user group must be specified. If you change a user from local to remote, the user can have an SSH key but cannot have a password.

If you use the **keyfile** parameter, the SSH key file should be placed in the /tmp directory before you run this command. When you run the command, the SSH key is copied into cluster state and activated for the user, and the input file is deleted.

An invocation example

```
chuser -remote no -usergrp Monitor -nokey jane
```

The resulting output:

```
No feedback
```

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

chusergrp

Use the **chusergrp** command to change the attributes of an existing user group.

Syntax

Parameters

-role *role_name*

(Optional) Specifies the role to be associated with users that belong to this group. One of the following roles must be selected: Monitor, CopyOperator, Service, Administrator, or SecurityAdmin.

-remote *yes* | *no*

(Optional) Specifies whether this user group should be used to set the role of remote users. Either the *yes* or *no* option must be set.

-ownershipgroup *owner_id* | *owner_name*

(Optional) The name or ID of the ownership group to which the object is being added.

-noownershipgroup

(Optional) If specified, the object is removed from the ownership group to which it belongs.

group_id* | *group_name

(Required) The ID or name of the user group whose attributes are to be changed.

Description

Use the **chusergrp** command to modify the attributes of an existing user group.

You must have the Security Administrator role to create, delete, or change a user. You can issue all commands except for **sainfo** and **satask** commands. These commands can only be issued by user superuser.

The roles of the default groups cannot be changed.

An invocation example

```
chusergrp -role Administrator admin
```

The resulting output:

```
No feedback
```

An invocation example changing the ownership of a user group

```
chusergrp -ownershipgroup 2 myusergroup
```

The following output is displayed:

```
No feedback
```

An invocation example moving the user group to no ownership

```
chusergrp -noownershipgroup myusergroup
```

The following output is displayed:

```
No feedback
```

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

lscurrentUser

Use the **lscurrentUser** command to display the name and role of the logged-in user.

Syntax

➔ **lscurrentUser** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. If you enter `-delim :` on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This command displays the name and role of the current user.

An invocation example

```
lscurrentuser
```

The resulting output:

```
name superuser
role_name SecurityAdmin
owner_id 0
owner_name tenantA
```

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

lsldap

Use the **lsldap** command to display the details for the system-wide Lightweight Directory Access Protocol (LDAP) configuration.

Syntax

➔ **lsldap** -nohdr -delim *delimiter* ➔

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim *delimiter*

(Optional) By default, in a concise view all columns of data are space-separated, with the width of each column set to the maximum width of each item of data. In a detailed view, each item of data is an individual row, and if you display headers, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. Enter **-delim :** on the command line, and the colon character (:) separates all items of data in a concise view (for example, the spacing of columns does not occur); in a detailed view, the specified *delimiter* separates the data from its header.

Description

This table provides the attribute values that can be displayed as output view data.

Table 126. <i>lsldap attribute values</i>	
Attribute	Value
type	Indicates the LDAP server type. The values are: <ul style="list-style-type: none">• ad indicates that it is an Active Directory server.• itds indicates that it is an IBM Tivoli Directory Server.• other indicates that it is another type of server.
enabled	Indicates whether native LDAP authentication is enabled. The value is yes or no/
error_sequence_number	Indicates the sequence number of non-fixed LDAP configuration error log. The value is a number (integer).
username	Indicates the binding user name or distinguished name. The value is an alphanumeric string or blank if there is no name.
security	Indicates the type of security in use. The values are: <ul style="list-style-type: none">• tls indicates that it is Transport Layer Security.• ssl indicates that it is Secure Socket Layer.• none indicates that there is no security.
user_attribute	Indicates the LDAP attribute that represents the user login.
group_attribute	Indicates the LDAP attribute that represents the user group membership.
audit_log_attribute	Indicates the LDAP attribute that represents the user name in audit log.
auth_cache_minutes	Indicates the period (in minutes) for which to cache session details.
nested_group_search	Indicates the handling of nested groups. The values are: <ul style="list-style-type: none">• off indicates that there is no nested group handling search.• client indicates that the system must search for nested groups on the client.• server indicates that the system must search for nested groups on the server.

An invocation example

```
lsldap -delim :
```

The resulting output:

```
type:ad
enabled:yes
error_sequence_number:12
username:admin@company.com
security:tls
user_attribute:SAMAccountName
group_attribute:memberOf
audit_log_attribute:userPrincipalName
auth_cache_minutes:10
nested_group_search:off
```

Use the **chldapserver** command to modify a Lightweight Directory Access Protocol (LDAP) server.

[chnaskey](#)

The **chnaskey** command provides an interface to set or reset the Secure Shell (SSH) private and public key credential pair used by communications between the Storwize V7000 Unified file modules and the control enclosure over the site 1 Gbps Ethernet LAN. This is required during the USB initialization of the Storwize V7000 Unified system.

[chownershipgroup](#)

The **chownershipgroup** command modifies the properties of an ownership group.

[chuser](#)

Use the **chuser** command to change the attributes of an existing user.

[chusergrp](#)

Use the **chusergrp** command to change the attributes of an existing user group.

[lscurrentuser](#)

Use the **lscurrentuser** command to display the name and role of the logged-in user.

[lsldapserver](#)

Use the **lsldapserver** command to display the most recent details for all configured Lightweight Directory Access Protocol (LDAP) servers.

[lsownershipgroup](#)

The **lsownershipgroup** command displays the ownership groups that are available in the system.

[lsuser](#)

Use the **lsuser** command to display a list of the users that is created on the system.

[lsusergrp](#)

Use the **lsusergrp** command to display a list of the user groups that is created on the system.

[mkldapserver](#)

Use the **mkldapserver** command to display the data used to create a Lightweight Directory Access Protocol (LDAP) server.

[mkownershipgroup](#)

The **mkownershipgroup** command creates an ownership group.

[mkuser](#)

Use the **mkuser** command to create either a local or a remote user to access a system.

[mkusergrp](#)

Use the **mkusergrp** command to create a new user group.

[rmldapserver](#)

Use the **rmldapserver** command to delete a Lightweight Directory Access Protocol (LDAP) server.

[rmownershipgroup](#)

The **rmownershipgroup** command deletes an ownership group.

[rmuser](#)

Use the **rmuser** command to delete a user.

[rmusergrp](#)

Use the **rmusergrp** command to delete a user group.

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

lsldapserver

Use the **lsldapserver** command to display the most recent details for all configured Lightweight Directory Access Protocol (LDAP) servers.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default, in a concise view all columns of data are space-separated, with the width of each column set to the maximum width of each item of data. In a detailed view, each item of data is an individual row, and if you display headers, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. Enter **-delim :** on the command line, and the colon character (:) separates all items of data in a concise view (for example, the spacing of columns does not occur); in a detailed view, the specified *delimiter* separates the data from its header.

ldap_server_id | ldap_server_name

(Optional) Specifies the ID or name for LDAP server that is being used.

Description

Remember:

- The base distinguished name (DN) is at the end of the concise view information; other fields must be added before the base DN.
- The command fails if a server is specified that does not exist.

This table provides the attribute values that can be displayed as output view data.

Table 127. lsldapserver attribute values	
Attribute	Value
id	Specifies the ID of the LDAP server.
name	Specifies the name of the LDAP server.
error_sequence_number	Specifies the sequence number of non-fixed LDAP server error log.
IP_address	Specifies either a server IP address (Internet Protocol Version 4 or 6), or a fully-qualified domain name (maximum of 64 characters).

Table 127. *lsldapserver* attribute values (continued)

Attribute	Value
port	Specifies the LDAP server port. The default value is 389. The value for TLS security is 389 and the value for SSL security is 636.
cert_set	Specifies the certificate setting if a certificate is configured.
preferred	Specifies the server preference (preferred server).
base_dn	Specifies the base distinguished name (DN) that is used in LDAP searches.

Description

This command displays details for the configured LDAP servers.

Note: There is a maximum of six configured LDAP servers.

A concise invocation example

```
lsldapserver -delim :
```

The resulting output:

```
id:name:error_sequence_number:IP_address:port:cert_set:preferred:base_dn
0:ldapserver0::192.135.60.3:389:no:yes:ou=users,dc=company,dc=com
1:ldapserver1:12:192.135.60.4:389:no:no:ou=users,dc=company,dc=com
2:ldapserver2::192.135.60.5:389:yes:yes:ou=users,dc=company,dc=com
3:ldapserver3::192.135.60.6:389:yes:no:ou=users,dc=company,dc=com
```

A detailed invocation example

```
lsldapserver -delim : ldapserver0
```

The resulting output:

```
id:0
name:ldapserver0
error_sequence_number:
IP_address:192.135.60.3
port:389
cert_set:no
preferred:yes
base_dn:ou=users,dc=company,dc=com
```

Use the **chuser** command to change the attributes of an existing user.

chusergrp

Use the **chusergrp** command to change the attributes of an existing user group.

lscurrentuser

Use the **lscurrentuser** command to display the name and role of the logged-in user.

lsldap

Use the **lsldap** command to display the details for the system-wide Lightweight Directory Access Protocol (LDAP) configuration.

lsownershipgroup

The **lsownershipgroup** command displays the ownership groups that are available in the system.

lsuser

Use the **lsuser** command to display a list of the users that is created on the system.

lsusergrp

Use the **lsusergrp** command to display a list of the user groups that is created on the system.

mkldapserver

Use the **mkldapserver** command to display the data used to create a Lightweight Directory Access Protocol (LDAP) server.

mkownershipgroup

The **mkownershipgroup** command creates an ownership group.

mkuser

Use the **mkuser** command to create either a local or a remote user to access a system.

mkusergrp

Use the **mkusergrp** command to create a new user group.

rmldapserver

Use the **rmldapserver** command to delete a Lightweight Directory Access Protocol (LDAP) server.

rmownershipgroup

The **rmownershipgroup** command deletes an ownership group.

rmuser

Use the **rmuser** command to delete a user.

rmusergrp

Use the **rmusergrp** command to delete a user group.

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

lsownershipgroup

The **lsownershipgroup** command displays the ownership groups that are available in the system.

Syntax

➤ `svcinfolsoownershipgroup` 

Parameters

owner_id | owner_name

(Optional) Specify the ID or the name of the ownership group to display.

Description

Use the **lsownershipgroup** command to display the ownership groups that are available in the system.

An invocation example

```
lsownershipgroup
```

The resulting output:

```
owner_id  owner_name
0         ownershipgroup0
1         ownershipgroup1
```

An invocation example

```
lsownershipgroup 0
```

The resulting output:

```
id 0
name ownershipgroup0
```

rmusergrp

Use the **rmusergrp** command to delete a user group.

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

lsuser

Use the **lsuser** command to display a list of the users that is created on the system.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. If you enter `-delim :` on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the SAN Volume Controller CLI:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (" "), as follows:

```
lsuser -filtervalue "usergrp_name=md*"
```

-filtervalue?

(Optional) Displays the valid filter attributes for the **-filtervalueattribute=value** parameter:

- password
- ssh_key
- remote
- usergrp_id
- usergrp_name

usergrp_name / usergrp_id

(Optional) Specifies the ID or name of the user for which the association is being deleted. If this parameter is specified, the detailed view for the specified user is displayed in the output. If you do not specify an ID or name, the concise view is displayed.

Description

This command displays a list of users that is created on the system.

A concise invocation example

```
lsuser
```

The resulting output:

id	name	password	ssh_key	remote	usergrp_id	usergrp_name	owner_id	owner_name
0	superuser	yes	no	no	0	SecurityAdmin		
1	user1	yes	no	no	6	usergrp1	1	tenant1
2	user2	yes	no	no	7	usergrp2	2	tenant2
3	user3	yes	no	no	8	usergrp3	3	tenant3
4	user4	yes	no	no	9	usergrp4		

A detailed invocation example

```
lsuser 1
```

The resulting output:

```
id 1
name user1
password yes
ssh_key no
```

```
remote no
usergrp_id 6
usergrp_name usergrp1
owner_id 1
owner_name tenant1
```

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

lsusergrp

Use the **lsusergrp** command to display a list of the user groups that is created on the system.

Syntax

Parameters

-nohdr

By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data is displayed, headings are not displayed.

-delim delimiter

By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue attribute=value

Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the CLI:

- The wildcard character is the asterisk (*), which must be used as the first or last character in the string.
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (" ").

```
lsusergrp -filtervalue "role=md*"
```

-filtervalue?

Displays the valid filter attributes for the **-filtervalue attribute=value** parameter:

- role_id
- role_name

- remote

usergrp_name / usergrp_id

Specifies the ID or name of the user group to view. If you do not specify an ID or name, all groups are displayed.

Description

This command displays a list of user groups that is created on the system.

An invocation example

```
lsusergrp
```

The resulting output

id	name	role	remote	owner_id	owner_name
0	SecurityAdmin	SecurityAdmin	no		
1	Administrator	Administrator	no		
2	CopyOperator	CopyOperator	no		
3	Service	Service	no		
4	Monitor	Monitor	no		
5	RestrictedAdmin	RestrictedAdmin	no		
6	usergrp1	Administrator	no	1	tenant1
7	usergrp2	Administrator	no	2	tenant2
8	usergrp3	Administrator	no	3	tenant3
9	usergrp4	Administrator	no		

An invocation example

```
lsusergrp 8
```

The resulting output

```
id 8
name usergrp3
role Administrator
remote no
owner_id 3
owner_name tenant3
```

mkusergrp

Use the **mkusergrp** command to create a new user group.

rmldapserver

Use the **rmldapserver** command to delete a Lightweight Directory Access Protocol (LDAP) server.

rmownershipgroup

The **rmownershipgroup** command deletes an ownership group.

rmuser

Use the **rmuser** command to delete a user.

rmusergrp

Use the **rmusergrp** command to delete a user group.

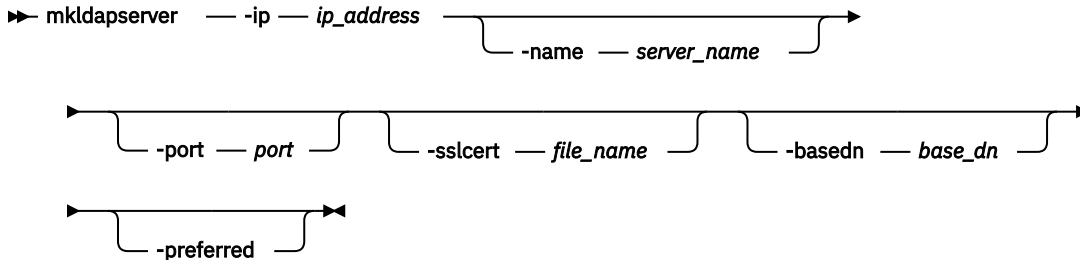

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

mkldapserver

Use the **mkldapserver** command to display the data used to create a Lightweight Directory Access Protocol (LDAP) server.

Syntax

Parameters

-ip *ip_address*

(Required) Specifies either a server IP address (Internet Protocol Version 4 or 6), or a fully qualified domain name (FQDN) (maximum of 64 characters). (FQDN is not supported by 840 AE1.) You can specify an optional fully qualified domain name after you establish a DNS server using the **mkdnserver** command.

-name *server_name*

(Optional) Specifies the LDAP server name.

-port *port*

(Optional) Specifies the LDAP server port. The default value (if you do not specify a value) is 389. If you specify TLS security the value is 389 and if you specify SSL security the value is 636.

-sslcrt *file_name*

(Optional) Set the SSL certificate.

-basedn *base_dn*

(Optional) Use the base distinguished name for search.

-preferred

(Optional) Specifies that this server is preferred over other configured LDAP servers.

Description

Important: During normal operation, LDAP requests are sent to **-preferred** servers depending on availability. If no servers are marked as **-preferred**, LDAP requests are sent to configured servers based on availability.

If **-sslcrt** is specified, the server certificate is verified while authenticating.

Note: The SSL certificate must exist on the current node.

The **-basedn** parameter indicates the distinguished name (DN) to use as a base from which to search for users in the LDAP directory. If Transport Layer Security (TLS) is enabled and **-sslcrt** is specified, the server certificate is verified during authentication. The secure socket layer (SSL) certificate must exist on the node being used, otherwise a server certificate is not checked.

The system must be configured with an appropriate version IP address when **-ip** is specified. The IP address specified with the **-ip** parameter must be of a version supported by the system. The certificate file must be in valid PEM format and have a maximum length of 12 kilobytes.

Distinguished names must be a sequence of **attribute=value** pairs separated by a comma (,), semi-colon(;), or plus sign (+) escaping special characters with a backslash (\) where appropriate, and

specified UTF-8 characters using their byte encoding. For example, \ , for commas or \C4\87 for the UTF-8 character c acute.

This command runs whether or not LDAP authentication is enabled.

Remember: There is a maximum of six configured LDAP servers. Attempting to create a seventh LDAP server returns an error.

An invocation example

```
mkldapserver -ip 192.135.60.3
```

The resulting output:

```
LDAP Server, id [0], successfully created
```

An invocation example - fully qualified domain name (900 AE2 and AE3)

```
mkldapserver -ip ldapservername.example.com
```

The resulting output:

```
LDAP Server, id [0], successfully created
```

Note: You can specify an optional fully qualified domain name after you establish a DNS server using the **mkdnsserver** command. You can then verify that the domain name(s) will resolve to IP addresses successfully by using the **sainfo host** command.

```
sainfo host -ip_or_name ldapservername.example.com
```

The resulting output:

```
ldapservername.example.com has address 192.135.60.3
```

Use the **mkldapserver** command to display the data used to create a Lightweight Directory Access Protocol (LDAP) server.

[mkuser](#)

Use the **mkuser** command to create either a local or a remote user to access a system.

[mkusergrp](#)

Use the **mkusergrp** command to create a new user group.

[rmldapserver](#)

Use the **rmldapserver** command to delete a Lightweight Directory Access Protocol (LDAP) server.

[rmownershipgroup](#)

The **rmownershipgroup** command deletes an ownership group.

[rmuser](#)

Use the **rmuser** command to delete a user.

[rmusergrp](#)

Use the **rmusergrp** command to delete a user group.

[testldapserver](#)

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

mkuser

Use the **mkuser** command to create either a local or a remote user to access a system.

Syntax

➤ **mkuser** — **-name** — *user_name* ➡

Parameters

-name user_name

(Required) Specifies the unique user name. The user name cannot start or end with a blank. The user name must consist of a string of 1 - 256 ASCII characters, with the exception of the following characters: %: " , * ' .

-remote | -usergrp

(Required) Specifies whether the user authenticates to the system using a remote authentication service or system authentication methods. Either the **remote** parameter or the **usergrp** parameter must be set. If **usergrp** is specified, it must be followed by *group_name* or *group_id* (see next parameter).

group_name | group_id

(Required if **usergrp** is specified) The ID or name of the user group with which the local user is to be associated.

-password 'cleartext_password'

(Optional) Specifies the password to be associated with the user. The password cannot start or end with a blank. It must consist of a string of 6 - 64 printable ASCII characters. You can optionally specify the password with the **password** parameter. **You must enclose the password in single quotation marks.** If you do not specify the password, the system prompts you for it before running the command and does not display the password that you type. You cannot specify a password if **remote** is set. **Do not enclose the password in single quotation marks if you use the prompt.**

-keyfile sshkey_filename

(Optional) Specifies the name of the file that contains the Secure Shell (SSH) public key.

Description

The **mkuser** command creates a new local or remote user to access a system. The command returns the ID of the created user.

You must have the Security Administrator role to create, delete, or change a user. You can issue all commands except for **sainfo** and **satask** commands. These commands can only be issued by user superuser.

If you create a local user, you must specify the existing user group that the user belongs to. All local users must have a group. The user group defines roles that provide the user with access to specific operations on the system. You must also specify either the **keyfile** or **password** parameter, or both.

If you create a remote user, you may specify the **keyfile** parameter. Remote users have their groups defined by the remote authentication service.

Up to 400 users can be defined on the system. You can also create new users and assign keys to them.

If you use the **keyfile** parameter, the SSH key file should be placed in the /tmp directory before running this command. When you run the command, the SSH key is copied into system state and activated for the user, and the input file is deleted.

An invocation example

```
mkuser -name jane -usergrp Service -password 'secret'
```

The resulting output:

```
User, id [1], successfully created
```

[chauthservice](#)

Use the **chauthservice** command to configure the remote authentication service of the system.

[chcurrentuser](#)

Use the **chcurrentuser** command to change the attributes of the current user.

[chldap](#)

Use the **chldap** command to change system-wide Lightweight Directory Access Protocol (LDAP) configuration. This command can be used to configure remote authentication with LDAP. These settings apply when authenticating against any of the LDAP servers configured using the **mkldapserver** command.

[chldapserver](#)

Use the **chldapserver** command to modify a Lightweight Directory Access Protocol (LDAP) server.

[chnaskey](#)

The **chnaskey** command provides an interface to set or reset the Secure Shell (SSH) private and public key credential pair used by communications between the Storwize V7000 Unified file modules and the control enclosure over the site 1 Gbps Ethernet LAN. This is required during the USB initialization of the Storwize V7000 Unified system.

[chownershipgroup](#)

The **chownershipgroup** command modifies the properties of an ownership group.

[chuser](#)

Use the **chuser** command to change the attributes of an existing user.

[chusergrp](#)

Use the **chusergrp** command to change the attributes of an existing user group.

[lscurrentuser](#)

Use the **lscurrentuser** command to display the name and role of the logged-in user.

[lsldap](#)

Use the **lsldap** command to display the details for the system-wide Lightweight Directory Access Protocol (LDAP) configuration.

[lsldapserver](#)

Use the **lsldapserver** command to display the most recent details for all configured Lightweight Directory Access Protocol (LDAP) servers.

lsownershipgroup

The **lsownershipgroup** command displays the ownership groups that are available in the system.

lsuser

Use the **lsuser** command to display a list of the users that is created on the system.

lsusergrp

Use the **lsusergrp** command to display a list of the user groups that is created on the system.

mkldapserver

Use the **mkldapserver** command to display the data used to create a Lightweight Directory Access Protocol (LDAP) server.

mkownershipgroup

The **mkownershipgroup** command creates an ownership group.

mkusergrp

Use the **mkusergrp** command to create a new user group.

rmlldapserver

Use the **rmlldapserver** command to delete a Lightweight Directory Access Protocol (LDAP) server.

rmownershipgroup

The **rmownershipgroup** command deletes an ownership group.

rmuser

Use the **rmuser** command to delete a user.

rmusergrp

Use the **rmusergrp** command to delete a user group.

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

mkusergrp

Use the **mkusergrp** command to create a new user group.

Syntax

```
➤ mkusergrp — -name — group_name — -role — role_id — role_name — -remote —
```

```
➤ — -ownershipgroup — owner_id / owner_name —
```

Parameters

-name *group_name*

(Required) Specifies the unique user group name. The group name cannot start or end with a blank. The group name must consist of a string of 1 - 64 ASCII characters, except for the following characters: %: " , * ' .

-role *role_id / name*

(Required) Specifies the role (by ID or name) to be associated with all users that belong to this user group. One of the following roles must be selected:

- Monitor
- CopyOperator
- Service

- Administrator
- SecurityAdmin
- VasaProvider
- RestrictedAdmin
- 3SiteAdmin

The role SecurityAdmin cannot be set for an owned user group.

-remote yes / no

(Optional) Specifies if this user group should be used to set the role of remote users. The default value is **no**.

-ownershipgroup owner_id / owner_name

(Optional) The name or ID of the ownership group to which the object is being added.

Description

The **mkusergrp** command creates a new user group to organize users of the SAN Volume Controller clustered system by role. Use the **lsusergrp** command to view a list of user groups that have been created on the clustered system.

You must have the security administrator role (SecurityAdmin role name) to create, delete, or change a user group.

Each user group has one role that determines the role of users that belong to that group. Use the **role** parameter to specify one of the following roles for the user group:

Monitor

Additionally, you can issue any information display command and the following commands:

- **finderr**
- **dumperrlog**
- **dumpinternallog**
- **chcurrentuser**
- **ping**
- **svcconfig backup**

CopyOperator

You can issue the following commands:

- **prestartfcconsistgrp**
- **startfcconsistgrp**
- **stopfcconsistgrp**
- **chfcconsistgrp**
- **prestartfcmap**
- **startfcmap**
- **stopfcmap**
- **chfcmap**
- **startrrconsistgrp**
- **stoprrconsistgrp**
- **switchrrconsistgrp**
- **chrrconsistgrp**
- **startrrrelationship**
- **stoprrrelationship**
- **switchrrrelationship**

- **chcrelationship**
- **chpartnership**

In addition, you can issue all of the commands that are allowed by the **Monitor** role.

Service

You can issue the following commands:

- **applysoftware**
- **setlocale**
- **addnode**
- **rmnode**
- **cherrstate**
- **writesernum**
- **detectmdisk**
- **includemdisk**
- **clearerrlog**
- **cleardumps**
- **settimezone**
- **stopsystem**
- **startstats**
- **stopstats**
- **settime**

In addition, you can issue all of the commands that are allowed by the **Monitor** role.

Administrator

You can issue any command other than:

- **chauthservice**
- **mkuser**
- **rmuser**
- **chuser**
- **mkusergrp**
- **rmusergrp**
- **chusergrp**
- **setpwdreset**

VASAProvider

The system uses this role to implement the VMware Virtual Volumes function. It provides a group with users that can be used by that software. You can issue any command other than:

- **chauthservice**
- **chldap**
- **chldapserver**
- **chsecurity**
- **chuser**
- **chusergrp**
- **mkldapserver**
- **mkuser**
- **mkusergrp**
- **rmldapserver**

- **rmuser**
- **rmusergrp**
- **setpwdreset**

SecurityAdmin

You can issue all commands except for **sainfo** and **satask** commands. These commands can only be issued by user superuser.

3SiteAdmin

A user in a group with this role is required for the use of the 3-site orchestrator function. For more information on the 3-site orchestrator function, refer to the documentation.

The command returns the ID of the created user group.

An invocation example

```
mkusergrp -name support -role Service
```

The resulting output:

```
User Group, id [5], successfully created
```

An invocation example

```
mkusergrp -role VasaProvider -name myVasaProvider
```

The resulting output:

```
User Group, id [5], successfully created
```

An invocation example

```
mkusergrp -role RestrictedAdmin -name myRestrictedAdmin
```

The resulting output:

```
User Group, id [5], successfully created
```

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

rmldapserver

Use the **rmldapserver** command to delete a Lightweight Directory Access Protocol (LDAP) server.

Syntax

➔ **rmldapserver** *ldap_server_id* *ldap_server_name* ➔

Parameters

ldap_server_id* | *ldap_server_name

(Required) Specifies the LDAP server ID or name to delete.

Description

Remember:

- If remote authentication with LDAP is enabled, the final LDAP server cannot be deleted. To delete the final LDAP server disable LDAP authentication by specifying **chauthservice -enable no**.
- The **rmldapserver** command can be specified whether or not LDAP authentication is enabled.

An invocation example

```
rmldapserver ldapserver0
```

The resulting output:

```
No feedback
```

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

rmuser

Use the **rmuser** command to delete a user.

Syntax

➤ **rmuser** 

Parameters

user_id or user_name

(Required) Specifies the user to be removed.

Description

Use the **rmuser** command to delete a user.

You must have the Security Administrator role to create, delete, or modify a user.

An invocation example

```
rmuser jane
```

The resulting output:

```
No feedback
```

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

rmusergrp

Use the **rmusergrp** command to delete a user group.

Syntax

➔ **rmusergrp** 

Parameters

-force

(Optional) Specifies that the user group should be deleted even if there are users in the group.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

group_id | group_name

(Required) The ID or name of the user group to be removed.

Description

Use the **rmusergrp** command to delete a user group.

You must have the Security Administrator role to create, delete, or change a user group.

User groups with users cannot normally be deleted. If you use the **force** parameter, the group is deleted and all of the users in that group are assigned to the Monitor group. Default user groups cannot be deleted, even if the **force** parameter is set.

An invocation example

```
rmusergrp support
```

The resulting output:

No feedback

rmuser

Use the **rmuser** command to delete a user.

testldapserver

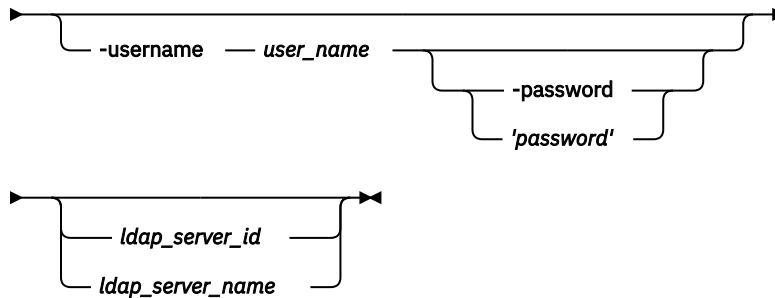

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

testldapserver

Use the **testldapserver** command to test a Lightweight Directory Access Protocol (LDAP) server.

Syntax

➤ **testldapserver** — **-delim** — *delimiter* ➔

Parameters

-delim delimiter

(Optional) By default, in a concise view all columns of data are space-separated, with the width of each column set to the maximum possible width of each item of data. In a detailed view, each item of data is an individual row, and if displaying headers, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a one-byte character. Enter **-delim :** on the command line, and the colon character (:) separates all items of data in a concise view (for example, the spacing of columns does not occur); in a detailed view, the specified *delimiter* separates the data from its header

-username user_name

(Optional) Specifies the user name to test.

-password 'password'

(Optional) Specifies the password to test. You can optionally specify the password with this parameter. **You must enclose the password in single quotation marks.** If you do not specify the password, the system prompts you for it before running the command and does not display the password that you type. **Do not enclose the password in single quotation marks if you use the prompt.**

Note: The **-password** parameter is only valid if **-username** is specified. The actual password does not need to be supplied.

ldap_server_id|ldap_server_name

(Optional) Specifies the LDAP server ID or name to test.

Description

The **testldapserver** command allows three levels of testing:

- Server connection test (issue **testldapserver** without supplying username or password). This verifies that a connection can be established with the server while authenticating using the configured administrator credentials according to the LDAP configuration.
- Server connection, LDAP configuration, and user authorization test (issue **testldapserver** with a username). This verifies that:
 - A connection can be established with the server while authenticating using the configured administrator credentials.
 - The LDAP attributes are correctly configured on the system.
 - The user has been assigned a role.
- Server connection, LDAP configuration, and user authentication test (issue **testldapserver** with a username and password). This verifies that:
 - A connection can be established with the server while authenticating using the configured administrator credentials.
 - The user authenticates with the supplied password

No specific server errors indicates success.

Important: This command works whether or not LDAP authentication is selected or enabled with the **chauthservice** command.

This table provides the attribute values that can be displayed as output view data.

Table 128. testldapserver attribute values	
Attribute	Value
id	LDAP server ID
name	LDAP server name
error	Critical server error (or success, depending on situation) encountered

An invocation example with one LDAP server and no specific user information

```
testldapserver -delim ":" ldapserver1
```

The resulting output:

```
id:name:error
1:ldapserver1:CMMVC7075I The LDAP task completed successfully
```

An invocation example with all LDAP servers using a UPN

```
testldapserver -username bloggs@company.com -delim ":"
```

The resulting output:

```
id:name:error
0:ldapserver0:CMMVC6518E The task has failed because no roles
are defined for the current user on the system.
1:ldapserver1:CMMVC7075I The LDAP task completed successfully.
2:ldapserver2:CMMVC7075I The LDAP task completed successfully.
```

chnaskey

The **chnaskey** command provides an interface to set or reset the Secure Shell (SSH) private and public key credential pair used by communications between the Storwize V7000 Unified file modules and the control enclosure over the site 1 Gbps Ethernet LAN. This is required during the USB initialization of the Storwize V7000 Unified system.

chownershipgroup

The **chownershipgroup** command modifies the properties of an ownership group.

chuser

Use the **chuser** command to change the attributes of an existing user.

chusergrp

Use the **chusergrp** command to change the attributes of an existing user group.

lscurrentuser

Use the **lscurrentuser** command to display the name and role of the logged-in user.

lsldap

Use the **lsldap** command to display the details for the system-wide Lightweight Directory Access Protocol (LDAP) configuration.

lsldapserver

Use the **lsldapserver** command to display the most recent details for all configured Lightweight Directory Access Protocol (LDAP) servers.

lsownershipgroup

The **lsownershipgroup** command displays the ownership groups that are available in the system.

lsuser

Use the **lsuser** command to display a list of the users that is created on the system.

lsusergrp

Use the **lsusergrp** command to display a list of the user groups that is created on the system.

mkldapserver

Use the **mkldapserver** command to display the data used to create a Lightweight Directory Access Protocol (LDAP) server.

mkownershipgroup

The **mkownershipgroup** command creates an ownership group.

mkuser

Use the **mkuser** command to create either a local or a remote user to access a system.

mkusergrp

Use the **mkusergrp** command to create a new user group.

rmlldapserver

Use the **rmlldapserver** command to delete a Lightweight Directory Access Protocol (LDAP) server.

rmownershipgroup

The **rmownershipgroup** command deletes an ownership group.

rmuser

Use the **rmuser** command to delete a user.

rmusergrp

Use the **rmusergrp** command to delete a user group.

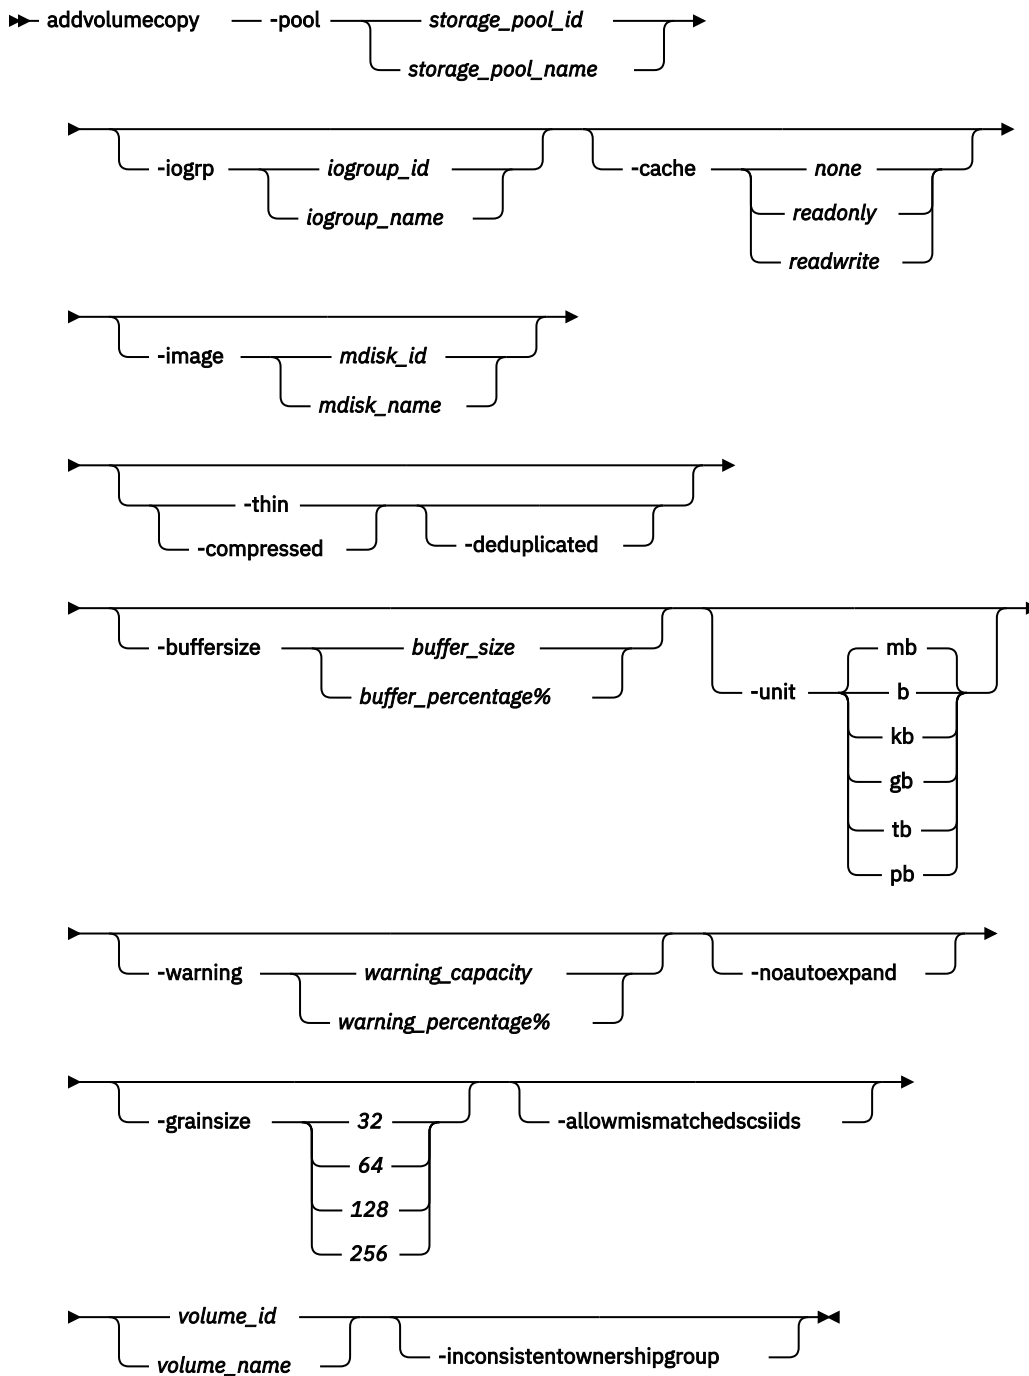

Chapter 30. Volume commands

Use the volume commands to work with volume options for the system.

addvolumecopy

Use the **addvolumecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

Syntax

Parameters

-pool *storage_pool_id* | *storage_pool_name*

(Required) Specifies the storage pool in which to create the new volume copy.

Remember: For stretched and hyperswap topology systems, the site of storage pool must not be the same as the site of the existing volume copy.

-iogrp *iogroup_id* | *iogroup_name*

(Optional) Specifies the I/O group that the new volume copy is cached in.

Note: This parameter applies only when you are creating a HyperSwap volume and requires that the system topology be hyperswap.

The I/O group must be in the same site as the storage pool that is being specified.

-cache *none / readonly / readwrite*

(Optional) Specifies the caching options for the volume copy. Valid entries are:

- **readwrite** enables the cache for the volume.
- **readonly** disables write caching but allows read caching for a volume.
- **none** disables the cache mode for the volume.

Note: This parameter applies only when you are creating a HyperSwap volume and requires that the system topology be hyperswap.

-image *mdisk_id / mdisk_name*

(Optional) Specifies that the volume copy is to be created (on any topology) in image mode and it specifies which currently unused MDisk to use.

Note: For a stretched or hyperswap topology system, the MDisk site must match the storage pool site. If the storage pool is empty, the MDisk site must be 1 or 2, and the MDisk site cannot be the same as the site of the existing volume copy.

-thin

(Optional) Specifies that the volume copy is to be created with thin provisioning. You cannot specify this parameter with **-compressed**.

Note: If you do not specify either **-thin** or **-compressed** parameters, the system creates a **standard-provisioned** volume copy.

-compressed

(Optional) Specifies that the volume copy is to be created compressed. You cannot specify this parameter with **-thin**.

-deduplicated

(Optional) Adds a deduplicated volume. If you specify **-deduplicated**, you must also specify **-thin** or **-compressed** because it applies only to thin or compressed volumes.

Note: Data deduplication works only with data reduction storage pools. You can only create deduplicated volumes and volume copies in an I/O group if no compressed volumes or volume copies exist in regular storage pools.

-bufferize *buffer_size / buffer_percentage%*

(Optional) Specifies the pool capacity the volume attempts to reserve as a buffer for thin-provisioned and compressed volumes. You must specify either **-thin** or **-compressed** with this parameter.

-warning *warning_capacity / warning_percentage%*

(Optional) Specifies a threshold at which a warning error log is generated for the volume copy. A warning is generated when the used disk capacity on the thin-provisioned or compressed copy exceeds the specified threshold. You can specify the threshold by using *warning_capacity* to specify a size, which defaults to MB unless the **-unit** parameter is specified.

Note: You can also specify a *warning_percentage%* to use a percentage of the volume size. If you do not specify a warning threshold, a default value of 80% is used. To disable warnings, specify 0.

You must specify either **-thin** or **-compressed** with this parameter.

-unit *b | kb | mb | gb | tb | pb*

(Optional) Specifies the data units for the **-bufferize** and **-warning** parameters.

-noautoexpand

(Optional) Specifies that the volume copy not automatically expand as it is written to; the available buffer capacity decreases as the used capacity increases. The copy goes offline if the buffer capacity is consumed.

The buffer capacity can be increased by specifying **expandvdisksize -rsize**. You must specify either **-thin** or **-compressed** with this parameter. If you do not specify this keyword, the copy automatically expands as it is written to.

-grainsize 32 / 64 / 128 / 256

(Optional) Sets the grain size (KB) for a thin-provisioned volume. If you are using the thin-provisioned volume in a FlashCopy map, use the same grain size as the map grain size for best performance. If you are using the thin-provisioned volume directly with a host system, use a small grain size. The grain size value must be 32, 64, 128, or 256 KB. The default is 256 KB.

-allowmismatchedscsiids

(Optional) When you create a HyperSwap volume, this parameter allows the master volume to have different SCSI LUN IDs in the assigned access I/O groups.

volume_id / volume_name

(Required) Specifies the volume to add the volume copy to.

-inconsistentownershipgroup

(Optional) If specified, this flag allows the object to be in inconsistent ownership.

Description

Use the **addvolume** command to add a copy to an existing volume. The new volume copy is synchronized with the current copy.

Note: A volume cannot have volume copies in different storage pools if cloud backup is enabled on the volume.

On some node types, you can create a compressed volume copy in a data reduction storage pool for an I/O group. A compressed volume copy in a data reduction pool can only be created in an I/O group with V5030, V7000, or SVC node types. You can create thin-provisioned volume copies on any node type. Volumes can also have **standard-provisioned** volume copies in data reduction storage pools.

You cannot specify **-buffersize** if the volume copy is created in a data reduction storage pool. Specify **-thin** or **-compressed** to enable thin provisioning or compression.

You cannot specify **-noautoexpand** when you create thin-provisioned or compressed volume copies from a data reduction storage pool.

You cannot create a volume copy that is a thin-provisioned or compressed volume in a data reduction storage pool, and the volume caching mode is none or readonly. You must specify **chvdisk** to change the volume caching mode to readwrite.

You cannot specify **-warning** for a thin-provisioned or compressed volume copy in a data reduction storage pool.

You cannot specify **-grainsize** for thin-provisioned and compressed volume copies in data reduction storage pools. This type of volume copy is created with a size of 8 KB.

Thin-provisioned or compressed volume copies in data reduction pools cannot be created if the data reduction storage pool is offline and requires recovery. If the recovery is still in progress, you must wait until the recovery is complete and the pool is in online state.

On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume to a second site.

A volume copy cannot be created in the same site as an existing copy of the volume. This command automatically adds the caching I/O group to the access I/O group set of the volume.

Note: HyperSwap volumes cannot be mapped to NVMe hosts.

When you create a HyperSwap volume, the system attempts to assign the same SCSI LUN ID for the master volume in all access I/O groups. If an identical SCSI LUN ID is not available in all access I/O groups, the command fails. Use the **-allowmismatchedscsiids** parameter to allow the system to allocate non-identical SCSI LUN IDs in the access I/O groups. The lowest value available in each access I/O group is used. It might not be the same in all access I/O groups. Make sure that the host supports this configuration.

Scenario 1

If the I/O group contains:

- At least one 8 GB node.
- At least one thin-provisioned or compressed volume in a data reduction pool.
- A FlashCopy bitmap size for that I/O group set beyond 1.5 GB.

The command fails due to insufficient resources available.

Scenario 2

When a thin-provisioned or compressed volume is created within a data reduction pool, the pool must have enough capacity to create more volumes that track SCSI unmap operations from the host. If this capacity is not available, the command fails.

Scenario 3

Volumes cannot be created in a data reduction pool if offline thin-provisioned or compressed volumes exist in a data reduction pool, either because of thin provisioning (out of space or corruption), or a component underneath thin provisioning is holding a volume in the pool offline.

Add a volume copy to an existing volume

```
addvolumecopy -pool 2 volume5
```

The detailed resulting output:

```
No feedback
```

Add a thin-provisioned volume copy to an existing volume

```
addvolumecopy -pool site2pool11 -thin 0
```

The detailed resulting output:

```
No feedback
```

Add a **standard-provisioned** image-mode volume copy

```
addvolumecopy -image mdisk12 -pool 3 volume2
```

The detailed resulting output:

```
No feedback
```

Add a thin-provisioned volume copy

```
addvolumecopy -pool paulgilbert17 -thin thinvdisk3
```

The detailed resulting output:

```
No feedback
```

An invocation example to add a deduplicated volume copy

```
addvolumecopy -pool datareductionpool10 -thin -deduplicated deduplicatedvolume6
```

The resulting output:

```
Vdisk [6] copy [1] successfully created
```

Related reference

addvdiskcopy

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolumecopy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisk

Use the **lsdependentvdisk** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolume group

Use the **mkvolume group** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

addvdiskcopy

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolumeecopy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

Note: The first syntax diagram depicts the addition of a sequential or striped mode volume. The second syntax diagram depicts the addition of an image mode volume.

Syntax

Parameters

-mdiskgrp *mdisk_group_id_list* / *mdisk_group_name_list*

(Required) Specifies the storage pools to use to create copies for the volume. You must specify a group for each copy that is being added.

Note: If the MDisk group is from a child pool, **-vtype** must be striped.

-mirrorwritepriority *latency* / *redundancy*

(Optional) Specifies how to configure the mirror write algorithm priority.

1. Choosing *latency* means a copy that is slow to respond to a write input/output (I/O) becomes unsynchronized, and the write I/O completes if the other copy successfully writes the data.

2. Choosing *redundancy* means a copy that is slow to respond to a write I/O synchronizes completion of the write I/O with the completion of the slower I/O to maintain synchronization.

-vtype seq | striped | image

(Optional) Specifies the virtualization type for the copy: sequential, striped, or image. The type can be different than the virtualization types for other copies on the volume. The default virtualization type is striped. If you specify the `-rsize auto` option or the `-import` option, you must also specify the `-vtype image` option.

Note: You cannot create an image or sequential mode copy from a child pool or data reduction pools.

-mdisk mdisk_id_list | mdisk_name_list

(Optional) Specifies one or more managed disks (MDisks). For sequential and image mode copies, you must specify a single MDisk that has sufficient free extents. For image mode copies, the MDisk must be in unmanaged mode. For sequential mode copies the MDisk must be in the managed mode.

-syncrate syncrate

(Optional) Specifies the copy synchronization rate. A value of zero prevents synchronization. For the supported `-syncrate` values and their corresponding rates, see the table in the command description section.

If not specified, the current value is unchanged.

-createsync

(Optional) Suppresses the synchronization of the new volume copy with the primary copy. Using this parameter can cause data corruption if the primary copy fails and leaves an unsynchronized secondary copy to provide data. Using this parameter can cause loss of read stability in unwritten areas if the primary copy fails, data is read from the primary copy, and then different data is read from the secondary copy.

Note: You cannot specify `-createsync` for a volume that is fast formatting.

-rsize disk_size | disk_size_percentage% | auto

(Optional) Makes the copy thin-provisioned and specifies the real size of the copy. Specify the `disk_size | disk_size_percentage` value by using an integer, or an integer immediately followed by the percent character (%). The default units for `disk_size` are megabytes (MB). To specify different units, use the `-unit` parameter. The `auto` option creates a volume copy that uses the entire size of the MDisk; if you specify the `-rsize auto` option, you must also specify the `-vtype image` option.

-deduplicated

(Optional) Adds a deduplicated volume. If you specify **-deduplicated**, you must also specify **-rsize** because it applies only to thin-provisioned or compressed volumes.

Note: Data deduplication works only with data reduction storage pools. You can only create deduplicated volumes and volume copies in an I/O group if no compressed volumes or volume copies exist in regular storage pools.

-compressed

(Optional) Adds exactly one copy to an existing volume that already has (only) one copy a volume, and enables compression. Requires the `-rsize` parameter also be specified.

Remember:

- You cannot specify this parameter with the `-grainsize` parameter.
- When you specify this parameter with the `-import` parameter, you must specify `-rsize auto`.

-warning disk_size | disk_size_percentage%

(Optional) Requires that the `-rsize` parameter also be specified. Generates a warning when the used disk capacity on the thin-provisioned copy first exceeds the specified threshold. You can specify a `disk_size` integer, which defaults to megabytes (MB) unless the `-unit` parameter is specified; or you can specify a `disk_size%`, which is a percentage of the volume size. If `-autoexpand` is enabled, the default value for `-warning` is 80% of the volume capacity. If `-autoexpand` is not enabled, the default value for warning is 80% of the real capacity. To disable warnings, specify **0**.

-autoexpand

(Optional) Requires that the `-rsize` parameter also be specified. Specifies that thin-provisioned copies automatically expand their real capacities by allocating new extents from their storage pool. If the `-autoexpand` parameter is specified, the `-rsize` parameter specifies a capacity that is reserved by the copy. It protects the copy from going offline when its storage pool runs out of space by allowing it to consume this reserved space first.

-grainsize 32 | 64 | 128 | 256

(Optional) Requires that the `-rsize` parameter also be specified. Sets the grain size (KB) for a thin-provisioned volume copy. The grain size value must be 32, 64, 128, or 256 KB. The default is 256 KB.

-unit b | kb | mb | gb | tb | pb

(Optional) Specifies the data units for the `-rsize` and `-warning` parameters.

-import

(Optional) Imports an image mode disk that contains a thin-provisioned volume into the system. Requires that the `-rsize` and `-vtype` image parameters also be specified.

-tier tier0_flash | tier1_flash | tier_enterprise | tier_nearline | tier_scm

(Optional) Specifies the MDisk tier when an image mode copy is added.

tier0_flash

Specifies a `tier0_flash` hard disk drive or an external MDisk for the newly discovered or external volume.

tier1_flash

Specifies a `tier1_flash` (or flash drive) hard disk drive or an external MDisk for the newly discovered or external volume.

tier_enterprise

Specifies a `tier_enterprise` hard disk drive or an external MDisk for the newly discovered or external volume.

tier_nearline

Specifies a `tier_nearline` hard disk drive or an external MDisk for the newly discovered or external volume.

tier_scm

Specifies a `tier_scm` hard disk drive or an external MDisk for the newly discovered or external volume.

-easytier on / off

(Optional) Determines whether the IBM Easy Tier function is allowed to move extents for this volume. If a volume copy is striped and not being migrated, see the settings in this table.

Table 129. Storage pool Easy Tier settings			
Storage pool Easy Tier setting	Number of tiers in the storage pool	Volume copy Easy Tier setting	Volume copy Easy Tier status
Off	One	Off	inactive (see note “1” on page 1534)
Off	One	On	inactive (see note “1” on page 1534)
Off	Two	Off	inactive (see note “1” on page 1534)
Off	Two	On	inactive (see note “1” on page 1534)
Measure	One	Off	measured (see note “2” on page 1534)
Measure	One	On	measured (see note “2” on page 1534)

Table 129. Storage pool Easy Tier settings (continued)			
Storage pool Easy Tier setting	Number of tiers in the storage pool	Volume copy Easy Tier setting	Volume copy Easy Tier status
Measure	Two	Off	measured (see note “2” on page 1534)
Measure	Two	On	measured (see note “2” on page 1534)
Auto	One	Off	measured (see note “2” on page 1534)
Auto	One	On	measured (see note “2” on page 1534)
Auto	Two	Off	balanced (see note “3” on page 1534)
Auto	Two	On	active (see note “4” on page 1534)
On	One	Off	measured (see note “2” on page 1534)
On	One	On	balanced (see note “3” on page 1534)
On	Two	Off	measured (see note “2” on page 1534)
On	Two	On	active (see note “4” on page 1534)
Notes: 1. When the volume copy status is inactive, no IBM Easy Tier functions are enabled for that volume copy. 2. When the volume copy status is measured, the IBM Easy Tier function collects usage statistics for the volume but automatic data placement is not active. 3. When the volume copy status is balanced, the IBM Easy Tier function enables performance-based pool balancing for that volume copy. 4. When the volume copy status is active, the IBM Easy Tier function operates in automatic data placement mode for that volume.			

If the volume copy is in image or sequential mode or is being migrated, the volume copy IBM Easy Tier status is measured instead of active.

The default Easy Tier setting for a storage pool is auto, and the default Easy Tier setting for a volume copy is on. If the setting is on, it means that Easy Tier functions except pool performance balancing are disabled for storage pools with a single tier, and that automatic data placement mode is enabled for all striped volume copies in a storage pool with two or more tiers.

-autodelete

(Optional) Specifies the primary copy is deleted after the secondary copy is synchronized.

jvdisk_name | vdisk_id

(Required) Specifies the volume to add the volume copy to, either by ID or by name.

-inconsistentownershipgroup

(Optional) If specified, this flag allows the object to be in inconsistent ownership.

Description

The **addvdiskcopy** command adds a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. Use the **mkdiskgrp** parameter to specify the storage pools that provide storage for the copy; the **lsmdiskgrp** command lists the available storage pools and the amount of available storage in each group.

The **addvdiskcopy** command can be specified with a file system volume, but must be used with the same storage pool for that volume.

Remember: Only compressed copies are allowed to be added to file system volumes.

The **addvdiskcopy** command adds a different volume copy, such as a copy created from an uncompressed to compressed conversion or a compressed to uncompressed conversion.

Note: A volume cannot have volume copies in different storage pools if cloud snapshot is enabled on the volume.

A thin-provisioned or compressed volume copy in a data reduction storage pool must not be a sequential or image mode volume. On some node types, you can create a compressed volume copy in a data reduction storage pool for an I/O group. A compressed volume copy in a data reduction pool can only be created in an I/O group with V5030, V7000, or SVC node types. You can create thin-provisioned volume copies on any node type. Use the **-autoexpand** parameter to create thin-provisioned or compressed volume copies from a data reduction storage pool. Volumes can also have **standard-provisioned** volume copies in data reduction storage pools.

You cannot create a volume copy that is a thin-provisioned or compressed volume in a data reduction storage pool, and the volume caching mode is none or readonly. You must specify **chvdisk** to change the volume caching mode to readwrite.

You cannot specify **-warning** for a thin-provisioned or compressed volume copy in a data reduction storage pool.

For thin-provisioned and compressed volume copies in data reduction storage pools, the Easy Tier mode for the volume is taken from the data reduction storage pool. The Easy Tier mode cannot be configured on these volume types.

You cannot specify **-grainsize** for thin-provisioned and compressed volume copies in data reduction storage pools. This type of volume copy is created with a size of 8 KB.

Thin-provisioned or compressed volume copies in data reduction pools cannot be created if the data reduction storage pool is offline and requires recovery. If the recovery is still in progress, you must wait until the recovery is complete and the pool is in online state.

An encryption key cannot be used when you add an image mode MDisk. To use encryption (when the MDisk has an encryption key), the MDisk must be self-encrypting.

Remember: You cannot add a volume copy if the volume to be copied is being formatted.

The virtualization types are defined as follows:

sequential (seq)

This policy requires the **-mdisk** parameter with a single managed disk as its argument. This MDisk must be in the managed mode.

It creates the volume by using extents from the given managed disk (assuming enough free extents exist on the managed disk).

striped

The striped policy is the default policy. If the **-vtype** parameter is not specified, this policy is used in its default form. That is, all managed disks in the storage pool are used to create the volume. The striping is at an extent level; one extent from each managed disk in the group is used. For example, a storage pool with 10 managed disks uses one extent from each managed disk, then it uses the 11th extent from the first managed disk, and so on.

If the **-mdisk** parameter is also specified, you can supply a list of managed disks to use as the stripe set. This list can include two or more managed disks from the same storage pool. The same circular

algorithm is used across the striped set. However, a single managed disk can be specified more than once in the list. For example, if you enter `-m 0:1:2:1`, the extents are from the following managed disks: 0, 1, 2, 1, 0, 1, 2, and so forth. All MDisk that are specified in the **-mdisk** parameter must be in managed mode.

image

This policy allows image mode volumes to be created when a managed disk already has data on it, perhaps from a previrtualized subsystem. When an image mode volume is created, it directly corresponds to the (previously unmanaged) managed disk that it was created from; therefore, volume logical block address (LBA) x equals managed disk LBA i . You can use this command to bring a nonvirtualized disk under the control of the system. After it is under the control of the system, you can migrate the volume from the single managed disk. When it is migrated, the volume is no longer an image mode volume.

You can add image mode volumes to an already populated storage pool with other types of volumes, such as a striped or sequential.

Note: An image mode copy must be at least as large as the volume that it is being added to, but any capacity beyond the size of the volume is not accessible.

The command returns the ID of the newly created volume copy.

Create the first compressed volume copy for an I/O group to activate compression. You cannot create or move a compressed volume copy to an I/O group that contains (at least) one node that does not support compressed volumes. You must use another I/O group, but note that it does not affect moving to the recovery I/O group.

Important:

- If the volume (or volume copy) is a target of a FlashCopy mapping with a source volume in an active-active relationship, the new storage pool must be in the same site as the source volume.
- If this command is used for a volume that is a master volume, an auxiliary volume, or a change volume of an active-active relationship, the new copy must be created in a storage pool of the same site as the existing volume copy.
- When you add an image mode copy, the site information for the MDisk being added must be well-defined and match the site information for any other MDisk in the storage pool.

The rate at which the volume copies resynchronize after loss of synchronization can be specified by using the **-syncrate** parameter. This table provides the relationship of the *syncrate* value to the data copied per second.

Note: These settings also affect the initial rate of formatting.

Table 130. Relationship between the syncrate value and the data copied per second	
User-specified syncrate attribute value	Data copied/sec
1 - 10	128 KB
11 - 20	256 KB
21 - 30	512 KB
31 - 40	1 MB
41 - 50	2 MB
51 - 60	4 MB
61 - 70	8 MB
71 - 80	16 MB
81 - 90	32 MB
91 - 100	64 MB

Scenario 1

If the I/O group contains:

- At least one 8 GB node.
- At least one thin-provisioned or compressed volume in a data reduction pool.
- A FlashCopy bitmap size for that I/O group set beyond 1.5 GB.

The command fails due to insufficient resources available.

Scenario 2

When a thin-provisioned or compressed volume is created within a data reduction pool, the pool must have enough capacity to create more volumes that track SCSI unmap operations from the host. If this capacity is not available, the command fails.

Scenario 3

Volumes cannot be created in a data reduction pool if offline thin-provisioned or compressed volumes exist in a data reduction pool, either because of thin provisioning (out of space or corruption), or a component underneath thin provisioning is holding a volume in the pool offline.

An invocation example

```
addvdiskcopy -mdiskgrp 0 -easytier off vdisk8
```

The resulting output:

```
Vdisk [8] copy [1] successfully created
```

An invocation example for specifying storage pools

```
addvdiskcopy -mdiskgrp 0 -vtype image -mdisk 13 -tier tier0_flash -easytier off vdisk9
```

The resulting output:

```
Vdisk [9] copy [1] successfully created
```

An invocation example for configuring a mirror write algorithm priority

```
addvdiskcopy -mdiskgrp 0 -mirrorwritepriority latency vdisk9
```

The resulting output:

```
Vdisk [9] copy [1] successfully created
```

An invocation example for adding a compressed volume copy

```
addvdiskcopy -mdiskgrp 1 -rsize 10% -compressed vdisk2
```

The resulting output:

```
Vdisk [2] copy [1] successfully created
```

An invocation example for adding a compressed volume copy

```
addvdiskcopy -mdiskgrp 0 -vtype image -mdisk 13 -tier tier_nearline vdisk9
```

The resulting output:

```
Vdisk [9] copy [1] successfully created
```

An invocation example to add a deduplicated volume copy

```
addvdiskcopy -mdiskgrp datareductionpool10 -rsize 0 -autoexpand -deduplicated  
deduplicatedvolume6
```

The resulting output:

```
Vdisk [6] copy [1] successfully created
```

addvolumecopy

Use the **addvolume****copy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskaccess

Use the **addvdisk****access** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyze****vdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyze****vdisk****bysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backup****volume** command to create a volume snapshot.

backupvolumegroup

Use the **backup****volume****group** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **ch****vdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **ch****volume****group** command to change volume group properties.

expandvdisksize

Use the **expand****vdisk****size** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expand****volume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **ls****dependent****vdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **ls****host****vdisk****map** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **ls****meta****data****vdisk** command to display the information for metadata volume.

lsrepairevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumegroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

Syntax

Parameters

-iogrp iogrp_id_list | iogrp_name_list

(Required) Specifies a list of I/O groups to add to the I/O group volume access set.

-allowmismatchedscsiids

(Optional) When you add new access I/O groups, this parameter allows the SCSI LUN IDs to be different than the currently assigned SCSI LUN IDs in existing access I/O groups.

vdisk_id / vdisk_name

(Required) Specifies the volume to which to add access through the specified I/O groups.

Description

If an I/O group is already a member of the access set, no error is generated and no action is taken for that I/O group. All host mappings for the volume are added to the I/O groups in the list. The **-force** option is not required to extend additional mappings to other I/O groups.

When an I/O group is added to the access set, it creates access to the volume from the hosts that are mapped to the volume from the nodes in the I/O group. If the volume is mapped twice, it is also mapped twice through all additional I/O groups.

You can add I/O groups to the volume access list if they are mapped to iSCSI hosts. This means that iSCSI hosts can access volumes that are accessible through multiple I/O groups (as well as a single I/O group).

Remember: The **-addvdiskaccess** command fails if:

- Any host (for which the volume has a host mapping) is not associated with an I/O group in the list.
- The host volume mapping limit is exceeded.
- The number of extra mappings added exceeds the clustered system limit for host volume mappings.
- If the protocol is set to NVMe and results in a volume that has more than one access I/O group, due to a limitation in the protocol.
- If the same SCSI LUN ID is not available in the new access I/O group.

Two mappings are created if a host is mapped to a volume with two I/O groups. Hosts are limited to 512 host-to-volume mappings, which means a host can be mapped to:

- 512 volumes in a single I/O group
- 256 volumes across two I/O groups
- 64 volumes across four I/O groups

The command fails if any host mapped to the volume is detected as a host system that does not support volumes mapped from multiple I/O groups.

The system assigns the same SCSI LUN ID allocated to the volume in other access I/O groups if it is available in the new access I/O groups. Using the **-allowmismatchedscsiids** parameter allows the system to allocate non-identical SCSI LUN IDs in the access I/O group. The lowest value available in each access I/O group is used. It might not be the same in all access I/O groups. Make sure that the host supports this configuration. This parameter is not supported for NVMe hosts. When a volume is mapped to a host that uses the NVMe protocol, the volume namespace ID (NSID) is assigned by the system. When you add access to a volume that already has different SCSI LUN IDs in its existing access I/O group, you must use **-allowmismatchedscsiids** or the command fails.

An invocation example

This example adds I/O group 2 to the volume access set for DB_Volume:

```
addvdiskaccess -iogrp 2 DB_Volume
```

The resulting output:

```
No feedback
```

An invocation example

This example adds I/O groups 2 and 3 to the volume access set for volume ID 3:

```
addvdiskaccess -iogrp 2:3 3
```

The resulting output:

```
No feedback
```

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappointies

Use the **lsvdiskfcmappointies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

Syntax

➔ **analyzevdisk** 

Parameters

-cancel

(Optional) Cancels an ongoing compression estimation.

vdisk_id / vdisk_name

(Required) Specifies the volume ID or name to queue for analysis.

Description

This command queues or cancels volume analysis. The order is based on the *vdisk_id* value.

Important: You cannot specify **analyzevdisk -cancel** for a volume that is not currently being analyzed (or is queued for analysis).

You can schedule an offline volume for analysis (no error message is displayed). The volume remains scheduled until it is back online and is analyzed according to its *vdisk id* value.

A concise invocation example to queue **vdisk 0** for analysis

```
analyzevdisk 0
```

The detailed resulting output:

```
No feedback
```

A concise invocation example to dequeue or cancel an ongoing analysis for **vdisk 0**

```
analyzevdisk -cancel 0
```

The detailed resulting output:

```
No feedback
```

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmapcopies

Use the **lsvdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the `lsvdisksyncprogress` command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumebackupgroup

Use the **mkvolumebackupgroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

Syntax

➡ analyzevdiskbysystem 

Parameters

-cancel

(Optional) Cancels a scheduled or pending compression estimate.

Description

This command schedules all existing volumes in system for [available capacity](#) analysis.

Volumes that are created after you specify the command are not evaluated. Use **analyzevdisk** to evaluate specific volumes.

A concise invocation example to queue vdisk 0 for analysis

```
analyzevdiskbysystem
```

The detailed resulting output:

```
No feedback
```

A concise invocation example to dequeue or cancel an ongoing analysis for vdisk 0

```
analyzevdiskbysystem -cancel
```

The detailed resulting output:

```
No feedback
```

[addvolumecopy](#)

Use the **addvolumecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdiskcopy](#)

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolumecopy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdiskaccess](#)

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyzevdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

[backupvolume](#)

Use the **backupvolume** command to create a volume snapshot.

[backupvolumegroup](#)

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

[chvdisk](#)

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

[chvolumegroup](#)

Use the **chvolumegroup** command to change volume group properties.

[expandvdisksize](#)

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

[rmmetadatavdisk](#)

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

[rmvdiskcopy](#)

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

[rmvdiskaccess](#)

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

[rmvdiskhostmap](#)

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

[rmvolume](#)

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeecopy](#)

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeegroup](#)

Use the **rmvolumeegroup** command to remove a volume group from a system.

[rmvolumebackupgeneration](#)

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

Syntax

➔ backupvolume 

Parameters

-full

(Optional) Specifies that the snapshot generation for the volume should be a full snapshot.

volume_name / volume_id

(Required) Specifies the volume name or ID for the volume being backed up. The value for the volume name must be an alphanumeric string and the value for the volume ID must be a number.

Description

This command creates a volume snapshot.

The command completes when the volume snapshot is taken, and the snapshot is asynchronously transferred to the cloud system.

Note: If a volume belongs to a volume group, you must specify **backupvolume group** instead of **backupvolume**.

An invocation example for creating a full snapshot generation that has existing volume snapshots on the cloud system

```
backupvolume -full vdisk7
```

The resulting output:

```
No feedback
```

An invocation example for creating a backup of a volume for the first time

```
backupvolume neymar7
```

The resulting output:

```
No feedback
```

An invocation example for creating a backup of a volume that has existing snapshots in the cloud

```
backupvolume jvardy6
```

The resulting output:

```
No feedback
```

An invocation example for creating a full snapshot for a volume that has existing snapshots in the cloud

```
backupvolume -full lmessi1
```

The resulting output:

```
No feedback
```

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

Syntax

➤ backupvolumegroup 

Parameters

-full

(Optional) Specifies a full backup for volume group members.

volumegroup_name / volumegroup_id

(Required) Specifies a volume group ID or name for the volume to back up. The value must be a number for the volume group ID and an alphanumeric string for the volume group name.

Description

This command creates a new snapshot for all of the volumes in a volume group.

The command completes as soon as a snapshot of the volume group is taken. The backup is asynchronously transferred to the cloud. If any of the volume members have a backup or restore in progress, any new volume group backup cannot be taken. The volume backup on each volume member needs to be enabled by using the **chvdisk** command to enable the volume backup for entire volume group.

An invocation example

To create a backup of a volume group for the first time:

```
backupvolumegroup volgroup1
```

The resulting output:

```
No feedback
```

An invocation example

To create a backup of a volume group that has existing backups in the cloud:

```
backupvolumegroup volgroup1
```

The resulting output:

```
No feedback
```

An invocation example

To create a full backup generation for a volume group that has existing backups in the cloud:

```
backupvolumegroup -full volgroup1
```

The resulting output:

```
No feedback
```

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmapcopies

Use the **lsvdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumeegroup

Use the **lsvolumeegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumeegroup

Use the **mkvolumeegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

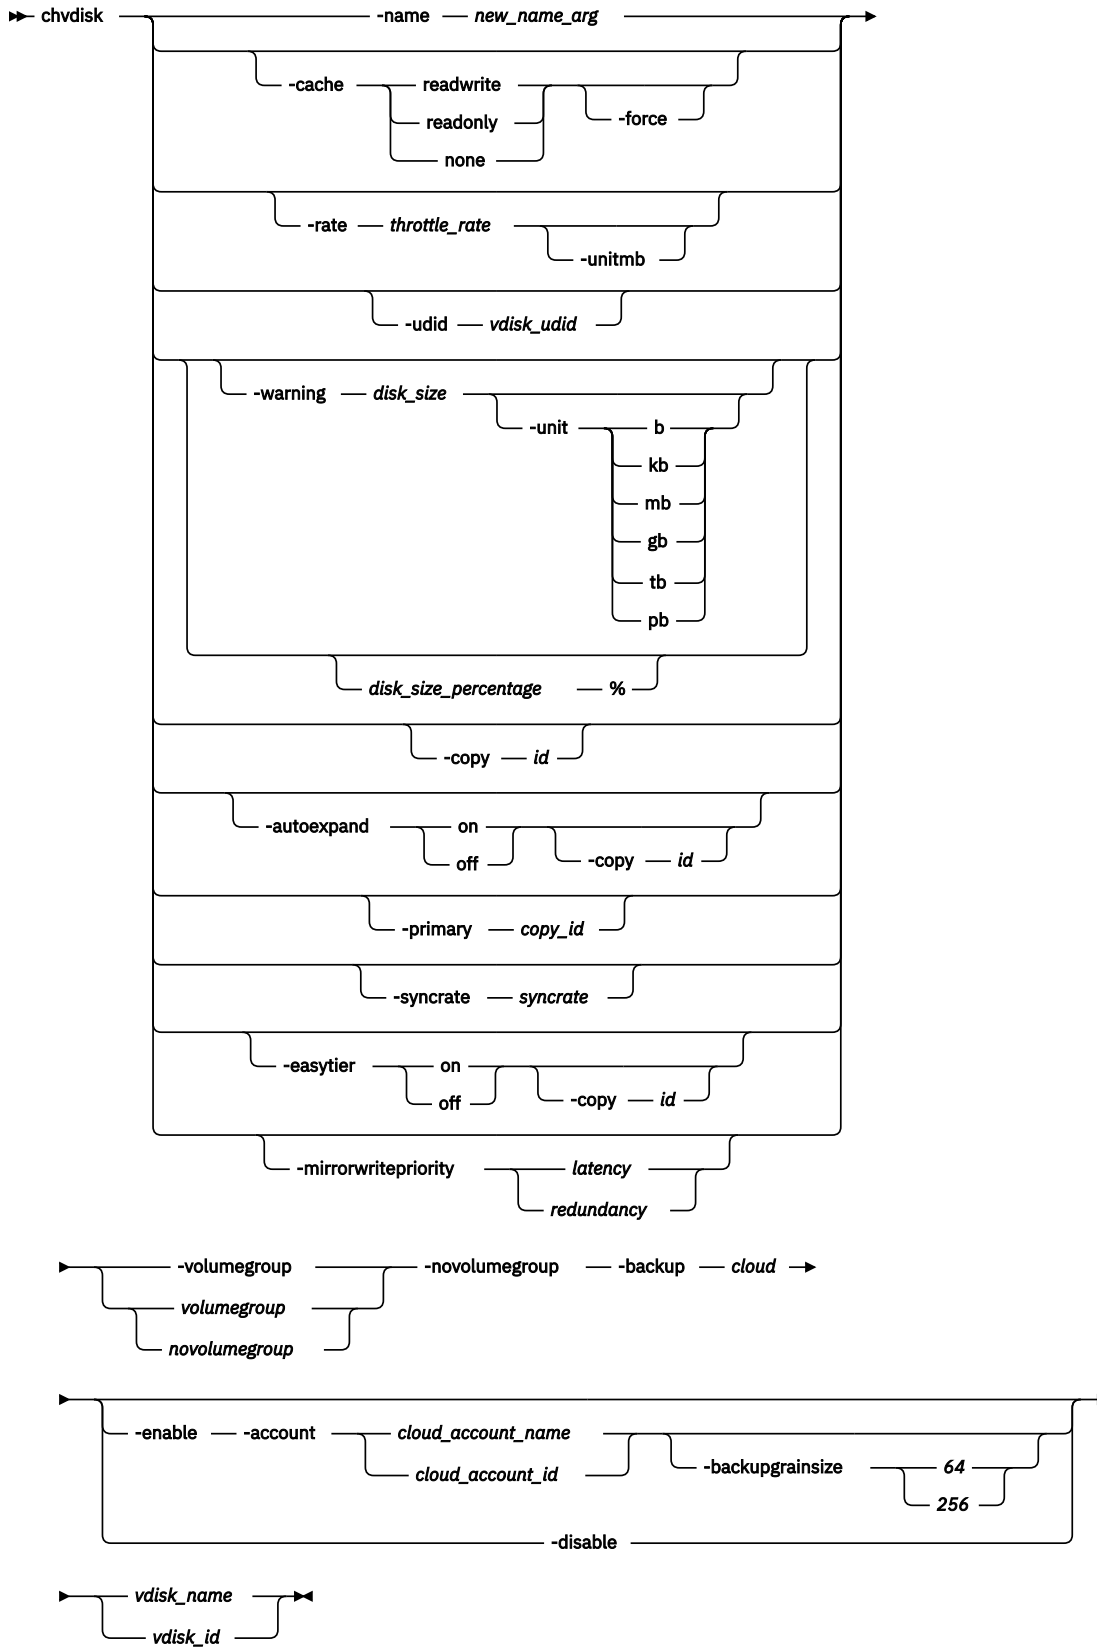

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

Syntax

Parameters

-name *new_name_arg*

(Optional) Specifies a new name to assign to the volume. You cannot use this parameter with the **-rate** or **-udid** parameters. This parameter is required if you do not use the **-rate** or **-udid** parameters.

Note: Do not use this parameter with file system volumes.

-cache *readwrite* | *readonly* | *none*

(Optional) Specifies the caching options for the volume. Valid entries are:

- Use *readwrite* to enable the cache for the volume.
- Use *readonly* to disable write caching and allow read caching for a volume.
- Use *none* to disable the cache mode for the volume.

The default is *readwrite*.

-force

(Optional) The **force** parameter can be used only for changing the caching mode. Use the **force** parameter with the **cache** parameter to specify that you want the system to change the cache mode of the volume even if the I/O group is offline. This option overrides the cache flush mechanism.

Attention: If the **force** parameter is used for changing the caching mode, the contents of the cache are discarded and the volume might be corrupted by the loss of the cached data. This corruption might occur if the system is able to destage all write data from the cache or not. Use the **force** parameter with caution.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

-rate *throttle_rate* -unitmb

(Optional) Specifies the I/O governing rate for the volume, which caps the amount of I/O that is accepted. The default *throttle_rate* units are I/Os. By default the *throttle_rate* is disabled. To change the *throttle_rate* units to megabits per second (MBps), specify the **-unitmb** parameter. The governing rate for a volume can be specified by I/Os or by MBps, but not both. However, you can set the rate to I/Os for some volumes and to MBps for others. When the input/output operations per second (IOPS) limit is configured on a volume, and it is smaller than 100 IOPS, the throttling logic rounds it to 100 IOPS. Even if throttle is set to a value smaller than 100 IOPS, the actual throttling occurs at 100 IOPS.

Note: To disable the throttling on a specific volume, set the *throttle_rate* value to zero.

You cannot use this parameter with the **-name** or **-udid** parameters.

-udid *vdisk_udid*

(Optional) Specifies the unit number (**-udid**) for the disk. The *vdisk_udid* is an identifier that is required to support OpenVMS hosts; no other systems use this parameter. Valid options are a decimal number in the range 0 - 32,767, or a hexadecimal number from 0 to 0x7FFF. A hexadecimal number must be preceded by 0x (for example, 0x1234). If you do not use the **-udid** parameter, the default **-udid** is 0.

You cannot use this parameter with the **-name** parameters.

-warning *disk_size* | *disk_size_percentage*

(Optional) Generates a warning when the used disk capacity on the thin-provisioned copy first exceeds the specified threshold. You can specify a *disk_size* integer, which defaults to MBs unless the **-unit** parameter is specified; or you can specify a *disk_size%*, which is a percentage of the volume size. To disable warnings, specify 0 or 0%.

-unit *b* | *kb* | *mb* | *gb* | *tb* | *pb*

(Optional) Specifies the data units to use for the **-warning***disk_size* parameter. The default unit value is MB.

-autoexpand on | off

(Optional) Specifies whether thin-provisioned volume copies automatically expand their real capacities by allocating new extents from their storage pool. To use this parameter, the volume must be thin-provisioned.

-copy id

(Optional) Specifies the copy to apply the changes to. You must specify this parameter with the **-autoexpand** or **-warning** parameter. The **-copy** parameter is required if the specified volume is mirrored and only one volume copy is thin-provisioned. If both copies are thin-provisioned and the **-copy** parameter is not specified, the specified **-autoexpand** or **-warning** parameter is set on both copies.

-primary copy_id

(Optional) Specifies the primary copy. Changing the primary copy takes effect only when the new primary copy is online and synchronized. If the new primary is online and synchronized when the command is issued, the change takes effect immediately. You cannot change the volume's primary copy if that primary copy has its autodelete flag is set to yes (on).

Important: You cannot use this parameter with a volume that is fast formatting.

-syncrate syncrate

(Optional) Specifies the copy synchronization rate. A value of zero (0) prevents synchronization. The default value is 50. See Table 131 on page 1569 for the supported **-syncrate** values and their corresponding rates. Use this parameter to alter the rate at which the **standard-provisioned** volume or mirrored volume format before synchronization.

-easytier on | off

(Optional) Enables or disables the IBM Easy Tier function.

Attention: Thin-provisioned and compressed volumes in a data reduction pool always have IBM Easy Tier on, regardless of the pool setting.

-mirrorwritepriority latency | redundancy

(Optional) Specifies how to configure the mirror write algorithm priority. A change to the mirror write priority is reflected in the volume's view immediately and in the volume's behavior after all prior input and output (I/O) completes.

1. Choosing *latency* means a copy that is slow to respond to a write I/O becomes unsynchronized, and the write I/O completes if the other copy successfully writes the data.
2. Choosing *redundancy* means a copy that is slow to respond to a write I/O synchronizes completion of the write I/O with the completion of the slower I/O to maintain synchronization.

-volumegroup volumegroup_name | volumegroup_id

(Optional)

Specifies a new volume group for a volume. This parameter is mutually exclusive with **-novolumegroup**.

-novolumegroup

(Optional) Specifies that a volume does not belong in any volume group. This parameter is mutually exclusive with **-volumegroup**.

-backup cloud

(Optional) Specifies the cloud snapshot type to enable or disable. The value must be **cloud**.

-enable

(Optional) Enables the backup or snapshot type that is specified with the **-backup** parameter.

-disable

(Optional) Disables the backup or snapshot type that is specified with the **-backup** parameter.

-account cloud_account_id | cloud_account_name

(Optional) Specifies the cloud account to use for the volume. You must specify **-enable** with this parameter.

-backupgrainsize 64 / 256

(Optional) Specifies the grain size (in KB) for volume mappings. The values are 64 and 256. You must specify **-enable** to use this parameter.

You can enable a volume for a cloud snapshot with one account. You cannot enable cloud backup on a volume for a second time on the same or different cloud account.

You cannot turn off the cloud snapshot function if a snapshot in progress. Any snapshot that is in progress must complete or be canceled.

vdisk_name / vdisk_id

(Required) Specifies the volume to modify, either by ID or by name.

Description

The **chvdisk** command modifies a single property of a volume. To change the volume name and modify the synchronization rate, for example, you must issue the command twice. If the volume is offline, use **recovervdisk** command to recover the volume and bring it back online.

Important: To change the caching I/O group for a volume or preferred node, use the **movevdisk** command.

A thin-provisioned or compressed copy that is in a data reduction storage pool must enable **-autoexpand**. If a volume contains a copy that is in a data reduction storage pool, the cache mode must be set to **readwrite**.

A thin-provisioned or compressed copy that is in a data reduction storage pool cannot have a warning threshold set. To change the warning threshold, you must specify the **-copy**.

You can specify a new name or label. Then, you can use the new name to refer to the volume.

You can set a limit on the number of I/O transactions that is accepted for this volume. It is set in terms of I/Os per second or MBs per second. By default, no I/O governing rate is set when a volume is created.

Attention: All capacities, including changes, must be in multiples of 512 bytes. An error occurs if you specify a capacity that is not a multiple of 512, which can happen only when byte units are used. The default capacity is in MB.

When the volume is created, no throttling is applied to it. Use the **-rate** parameter to change it. To change the volume back to an unthrottled state, specify 0 (zero) with the **-rate** parameter.

For thin-provisioned and compressed volume copies in data reduction pools, the Easy Tier status is derived from the data reduction pool as the data is managed by a central data disk. Therefore, the Easy Tier mode cannot be turned off on these volume types. The thin-provisioned and compressed volumes in a data reduction pool always have Easy Tier on, regardless of the pool setting. The Easy Tier setting is a combination of pool and volume setting, as detailed in a table in the help for **mkvdisk**. Leaving easy tier always on for the volume allows the pool setting to be the one that switches it on or off. For **standard-provisioned** volumes in a data reduction pool, Easy Tier can be turned both on and off.

The rate at which the volume copies resynchronize after loss of synchronization can be specified by using the **-syncrate** parameter. This table provides the relationship of the *syncrate* value to the data copied per second.

Note: These settings also affect the initial rate of formatting.

Table 131. Relationship between the syncrate value and the data copied per second	
User-specified <i>syncrate</i> attribute value	Data copied/sec
1 - 10	128 KB
11 - 20	256 KB
21 - 30	512 KB
31 - 40	1 MB

<i>Table 131. Relationship between the syncrate value and the data copied per second (continued)</i>	
User-specified syncrate attribute value	Data copied/sec
41 - 50	2 MB
51 - 60	4 MB
61 - 70	8 MB
71 - 80	16 MB
81 - 90	32 MB
91 - 100	64 MB

An invocation example

```
chvdisk -rate 2040 1
```

The following output is displayed:

```
No feedback
```

An invocation example

```
chvdisk -cache readonly 1
```

The following output is displayed:

```
No feedback
```

An invocation example

```
chvdisk -volume group 1 vdisk2
```

The following output is displayed:

```
No feedback
```

An invocation example

To enable a cloud snapshot for a volume, enter the following command:

```
chvdisk -backup cloud -enable -account myVardyj vdisk7
```

The following output is displayed:

```
No feedback
```

An invocation example

To disable a cloud snapshot for a volume, enter the following command:

```
chvdisk -backup cloud -disable vdisk7
```

The following output is displayed:

```
No feedback
```

Related reference

addvolumecopy

Use the **addvolume****copy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdisk****copy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume****copy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdisk****access** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdisk****bysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolume****group** command to create a new snapshot for all of the volumes in a volume group.

chvolumegroup

Use the **chvolume****group** command to change volume group properties.

expandvdisksize

Use the **expandvdisk****size** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisk** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdisk****map** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdisk****copy****progress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdisk****copy****progress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdisk****copy** command to list the thin-provisioned copies of the specified volumes.

lsdisk

Use the **lsdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmapcopies

Use the **lsvdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumegroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

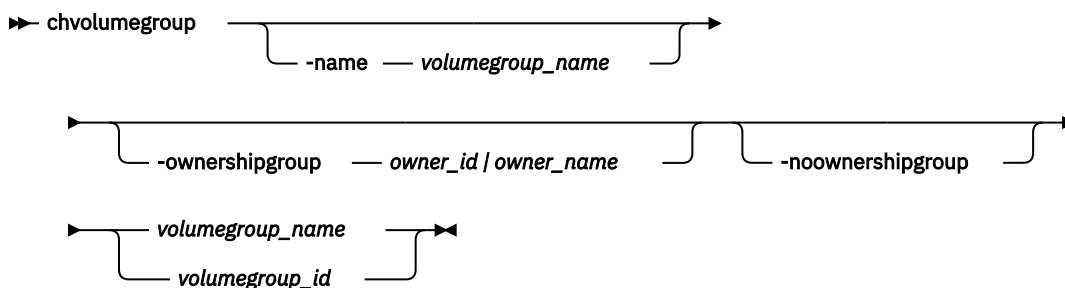

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

chvolumebackup

Use the **chvolumebackup** command to change volume group properties.

Syntax

Parameters

-name volumegroup_name

(Optional) Specifies a new volume group name. The value must be an alphanumeric string.

-ownershipgroup owner_id / owner_name

(Optional) The name or ID of the ownership group to which the object is being added.

-noownershipgroup

(Optional) If specified, the object is removed from the ownership group to which it belongs.

volumegroup_name / volumegroup_id

(Required) Specifies the volume group name or group ID for the volume you want to modify. The value must be a number for the volume group ID, and an alphanumeric string for the volume group name.

Description

This command changes volume group properties.

An invocation example

```
chvolume group -name newname1 1
```

The resulting output:

```
No feedback
```

An invocation example changing the ownership of a volume group

```
chvolume group -ownershipgroup 2 myvolume group
```

The following output is displayed:

```
No feedback
```

An invocation example moving the volume group to no ownership

```
chvolume group -noownershipgroup myvolume group
```

The following output is displayed:

```
No feedback
```

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmapcopies

Use the **lsvdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumebackupgroup

Use the **mkvolumebackupgroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

[recovervdiskbycluster](#) (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

[recovervdiskbyiogrp](#)

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

[recovervdiskbysystem](#)

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

[repairsevdiskcopy](#)

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

[repairvdiskcopy](#)

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

[restorevolume](#)

Use the **restorevolume** command to restore a volume from a snapshot generation.

[rmvdisk](#)

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

[rmmetadatavdisk](#)

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

[rmvdiskcopy](#)

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

[rmvdiskaccess](#)

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

[rmvdiskhostmap](#)

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

[rmvolume](#)

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeecopy](#)

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeegroup](#)

Use the **rmvolumeegroup** command to remove a volume group from a system.

[rmvolumebackupgeneration](#)

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

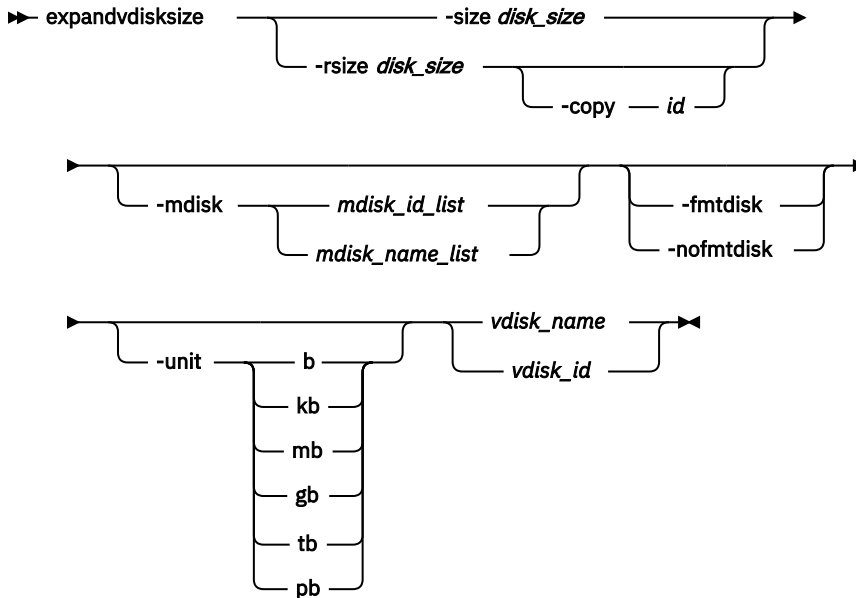

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

Syntax

Parameters

-size disk_size

(Required) Specifies the capacity by which the volume is expanded. Disk size is used with the value of the unit. All capacities, including changes must be in multiples of 512 bytes. An error occurs if you specify a capacity that is not a multiple of 512, which can only occur when byte units (**-unit b**) are used. However, an entire extent is reserved even if it is only partially used. The default *disk_size* unit is megabytes (MB). You cannot specify the **-size** parameter with the **-rsize** parameter. You must specify either **-size** or **-rsize**. If the volume is thin-provisioned, MDisk cannot be specified.

-rsize disk_size

(Optional) Specifies the capacity by which to increase the real size of a thin-provisioned volume. Specify the *disk_size* value by using an integer. Specify the unit for a *disk_size* integer by using the **-unit** parameter; the default unit is megabytes (MB). The **-rsize** value can be greater than, equal to, or less than the size of the volume. You cannot specify the **-rsize** parameter with the **-size** parameter. You must specify either **-size** or **-rsize**.

-copy id

(Optional) Specifies the copy to change the real capacity for. You must also specify the **-rsize** parameter; you can only modify the real capacity of a volume copy. The **-copy** parameter is required if the specified volume is mirrored and only one copy is thin-provisioned. If the volume is mirrored, both copies are thin-provisioned and **-copy** is not specified, both copies are modified by the same amount.

-mdisk mdisk_id_list / mdisk_name_list

(Optional) Specifies the list of one or more MDisk to be used as the stripe set. The extents that expand the volume come from the specified list of MDisk. All MDisk in the list must be part of the same storage pool. The **-mdisk** parameter cannot be used if the specified volume is mirrored.

-fmtdisk

(Optional) Specifies that the volume be formatted before use. This flag formats the new extents that have been added to the volume as a result of the **expandvdiskspace** command. The **expandvdiskspace** command completes asynchronously if you use this parameter. Fast formatting is on by default for standard-provisioned volumes.

-nofmtdisk

(Optional) Disables fast format for the newly expanded region of the [standard-provisioned](#) volume.

-unit b | kb | mb | gb | tb | pb

(Optional) Specifies the *disk_size* unit for the **-size** or **-rsize** parameter. The default value is megabytes (MB).

vdisk_name | vdisk_id

(Required) Specifies the volume to modify, either by ID or by name.

Description

Use the **expandvdiskspace** command to expand the writable capacity that is allocated to a particular volume by the specified amount.

The command can also be used to expand the provisioned capacity of a thin-provisioned volume without altering the writable capacity that is assigned to the volume. To change the capacity of a non-thin-provisioned volume, or the provisioned capacity of a thin-provisioned volume, use the **-size** parameter. To change the real capacity of a thin-provisioned volume, use the **-rsize** parameter.

Note: You can expand the capacity of any volume in a Global Mirror or Metro Mirror relationship that is in *consistent_synchronized* state. You cannot expand the capacity for these types of volumes:

- Volumes in HyperSwap relationships or in Global Mirror relationships that are operating in *cycling* mode. Use the **expandvolume** command to expand HyperSwap volumes.
- Volumes in relationships where a change volume is configured.
- Mirrored volumes that have at least one [standard-provisioned](#) copy.

Note: You cannot expand the capacity of any volume in a Global Mirror with change volumes relationship or in a HyperSwap relationship. Use the **expandvolume** command to expand HyperSwap volumes. To expand the capacity of a volume in a Global Mirror or Metro Mirror relationship:

1. Delete the relationship.
2. Increase the size of all the volumes. All volumes in a relationship must have the exact same size (provisioned capacity).
3. Re-create the relationship with the larger volumes.

When the mirror is restarted, it does a complete initial synchronization, replicating the entire primary volume to the secondary volume.

You cannot expand the capacity of any volume in a FlashCopy mapping, regardless of whether it is a source or target, or what state the mapping is in. You can expand the capacity of a volume in a FlashCopy mapping:

1. Delete all the mappings in that FlashCopy tree. (If there is a root source volume and some targets are either directly or cascaded off of other targets, the entire tree must be deleted.)
2. Increase the size of all volumes in the original FlashCopy tree. All volumes in a tree must be the same size (provisioned capacity).
3. Re-create all the FlashCopy mappings with the new larger volumes.

When a FlashCopy is restarted after being deleted (including if it is an incremental FlashCopy) the entire volume becomes part of any background copy because it is the start of a new mapping.

Note: The default capacity units are MB.

When a volume is expanded, the virtualization policy can change. Its mode becomes striped even if it was previously sequential. See the **mkvdisk** command for details of the virtualization policies.

To run the **expandvdisksize** command on a mirrored volume, all copies of the volume must be synchronized. The command formats all copies of a mirrored volume automatically.

Remember:

1. You cannot resize (expand) an image mode volume.
2. You cannot resize (expand) a volume that is part of a file system.
3. You cannot resize (expand) volume if that volume is being fast formatted. (Additionally, you cannot specify **shrinkvdisksize** to resize (shrink) for a volume that is fast formatting.)
4. You cannot resize (expand) a volume if cloud snapshot is enabled on that volume.
5. You cannot specify **expandvdisksize -resize** to expand (resize) a thin or compressed volume copy that is in a data reduction pool.
6. You cannot specify **expandvdisksize -mdisk** to resize (expand) a volume when a volume is being migrated.

You must expand both volumes in a relationship to maintain full operation of the system. To perform this task:

1. Expand the secondary volume by the required extra capacity.
2. Expand the primary volume by the required extra capacity.

An invocation example to increase the capacity of vdisk1 by 2048 bytes using extents from two MDisks (and to format the new part of the volume)

```
expandvdisksize -size 2048 -unit b -mdisk mdisk0:mdisk1 -fmtdisk vdisk1
```

The resulting output:

```
No feedback
```

An invocation example to increase the capacity of vdisk1 by 100 MB using extents from two MDisks (and to format the new part of the volume)

```
expandvdisksize -size 100 -unit mb -mdisk mdisk0:mdisk1 -fmtdisk vdisk1
```

The resulting output:

```
No feedback
```

An invocation example to increase the real capacity of thin-provisioned vdisk2 by 100 MB without changing the provisioned capacity (and to spread the extents across all MDisks in the storage pool)

```
expandvdisksize -resize 100 -unit mb vdisk2
```

The resulting output:

```
No feedback
```

An invocation example to increase the real capacity of thin-provisioned volume copy id 1 of mirrored volume vdisk3 by 100 MB

```
expandvdisksize -resize 100 -unit mb -copy 1 vdisk3
```

The resulting output:

```
No feedback
```

Related reference

addvolumecopy

Use the **addvolumecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolumecopy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmapcopies

Use the **lsvdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumegroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolume group

Use the **mkvolume group** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Description

Restricted users cannot use this command.

Note: You can expand the size of HyperSwap volumes provided:

- All copies of the volume are synchronized.
- All copies of the volume are thin or compressed.
- There are no mirrored copies.
- The volume is not in a consistency group. To expand the volume, you must remove the active-active relationship for the volume from the remote copy consistency group. The active-active relationship can be added back to the consistency group after the volume is expanded.

An invocation example to increase the capacity of volume5 by 10 GB

```
expandvolume -size 10 -unit gb volume5
```

The resulting output:

```
No feedback
```

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

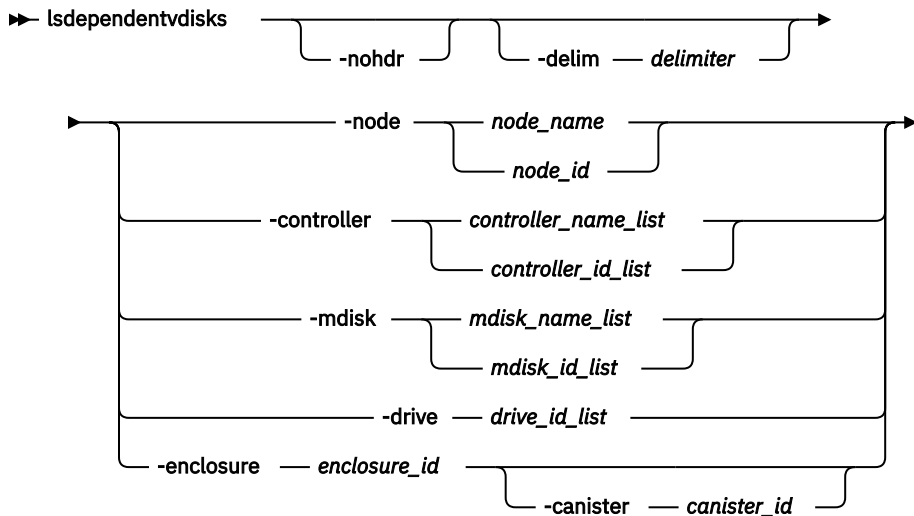

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-node node_name / node_id

(Optional) Specifies the node for which volume dependency is required.

-controller controller_name_list / controller_id_list

(Optional) Specifies the controllers for which volume dependency is required.

-mdisk mdkisk_name_list / mdkisk_id_list

(Optional) Specifies the MDisks for which volume dependency is required.

-drive

(Optional) Specifies the drives for which volume dependency is required. There is a maximum of 128 entries.

-enclosure enclosure_id

(Optional) Specifies the enclosure for which volume dependency is required. You can remove a control enclosure without affecting your other data.

-canister *canister_id*

(Optional) Specifies an enclosure canister. The possible values are 1 and 2.

Description

Use this command to view which volumes go offline if you remove a specific piece of hardware from the system. Use this command to determine which volumes are affected before undergoing maintenance.

An invocation example

```
lsdependentvdisks -delim : -drive 0:1
```

The resulting output:

```
vdisk_id:vdisk_name  
4:vdisk4  
5:vdisk5
```

Note: This means that if drives 0 and 1 are removed, then volume vdisk4 and volume vdisk5 go offline.

Related reference

addvolume

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdisk

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolume

Use the **backupvolume** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolume

Use the **chvolume** command to change volume group properties.

expandvdisk

Use the **expandvdisk** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumegroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

host_id / host_name

(Optional) Specifies the host in terms of its ID or name. The command displays a list of all the volumes that are mapped to the specified host and the Small Computer System Interface (SCSI) ID by which they are mapped. If you do not specify a host ID or name, the command displays a list of all recognized volume mappings.

Description

This command displays a list of volume IDs and names. These volumes are the volumes that are mapped to the specified host; that is, they are visible to the specified host. The SCSI LUN ID is also displayed. This SCSI LUN ID is the ID by which the volume is recognized by the host.

Each volume that is exported by the system is assigned a unique virtual path (VPATH) number. This number identifies the volume and determines which volume corresponds to the volume that the hosts recognize. This procedure must be completed by using the command-line interface.

For a specific volume based on which operating system and multipath software are used, you can use different commands to determine the VPATH serial number. For example, issuing **datapath query device** finds the VPATH serial number for volumes that are mapped to AIX `sddpcm`.

Find the host that is defined to the system that corresponds with the host that you are working with.

1. The worldwide port names (WWPNs) are an attribute of the host bus adapter (HBA). You can find the WWPNs by looking at the device definitions that are stored by your operating system. For example, on AIX® they are in the Object Data Manager (ODM), in Windows® they are in the Device Manager details for the specified HBA.
2. Verify which host is defined to the system that these ports belong to. The ports are stored as part of the detailed view, so you must list each host in turn by issuing the following command:

```
lshost host_name / host_id
```

where *host_name* / *host_id* is the name or ID of the host. Check for matching WWPNs.

Note: Consider this when you name your hosts. For example, if the actual host is called *orange*, also name the host that is defined to the system *orange*.

When you define the *hostname* and the *vpath serial number* to the system, issue the following command:

```
lshostvdiskmap hostname
```

where *hostname* is the name of the host. A list is displayed. Look for the volume UID that matches the *vpath serial number* and record the volume name or ID.

The command returns the following values:

id

Indicates the host ID in the output for **lshostvdiskmap**.

name

Indicates the host name in the output for **lshostvdiskmap**.

SCSI_id

Specifies the SCSI ID for SCSI mappings. This field is blank for NVMe mappings.

host_cluster_id

Indicates the unique ID for a host system.

host_cluster_name

Indicates the unique name for a host system.

vdisk_id

Specifies the UID of the volume or the NVMe namespace GUID.

vdisk_name

Indicates the name of the volume.

vdisk_UID

Indicates the UID of the volume.

IO_group_id

Indicates the ID of the input/output (I/O) group in which the host volume mapping exists.

IO_group_name

Specifies the name of I/O group in which the host volume mapping exists.

protocol

Indicates the protocol that is used by the hosts mapping this volume. The values are **scsi** or **nvme**.

An invocation example

```
lshostvdiskmap -delim : 2
```

The resulting output:

```
id:name:SCSI_id:host_id:host_name:vdisk_id:vdisk_name:vdisk_UID:IO_group_id:IO_group_name
2:host2:0:5:var1:10:vdisk10:600507680195800150000000000000A:0:iogrp0
2:host2:1:4:var2:11:vdisk11:600507680195800150000000000000B:1:iogrp1
2:host2:2:3:var3:12:vdisk12:600507680195800150000000000000C:0:iogrp0
2:host2:3:2:var4:13:vdisk13:600507680195800150000000000000D:1:iogrp1
2:host2:4:1:var5:14:vdisk14:600507680195800150000000000000E:1:iogrp0
```

An invocation example for a SCSI host

```
lshostvdiskmap host5
```

The resulting output:

id	name	SCSI_id	vdisk_id	vdisk_name	vdisk_UID	IO_group_id	IO_group_name
mapping_type	host_cluster_id	host_cluster_name	protocol				
5	host5	0	4	vdisk4	6005076400B10001A000000000000004	0	io_grp0
private				scsi			
5	host5	1	5	vdisk5	6005076400B10001A000000000000005	0	io_grp0
private				scsi			
5	host5	2	6	vdisk6	6005076400B10001A000000000000006	0	io_grp0
private				scsi			
5	host5	3	7	vdisk7	6005076400B10001A000000000000007	0	io_grp0
private				scsi			

An invocation example for an NVMe host

```
lshostvdiskmap 6
```

The resulting output:

id	name	SCSI_id	vdisk_id	vdisk_name	vdisk_UID	IO_group_id
IO_group_name	mapping_type	host	cluster_id	host_cluster_name	protocol	
6	nvmeServer6	8	vdisk8	A000000000000000080050760400B10001	0	
io_grp0	private			nvme		
6	nvmeServer6	9	vdisk9	A000000000000000090050760400B10001	0

addvolumecopy

Use the **addvolume**copy command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdisk**copy command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume**copy command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdisk**access command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyze**vdisk command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyze**vdiskbysystem command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backup**volume command to create a volume snapshot.

backupvolumegroup

Use the **backup**volumegroup command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolume**group command to change volume group properties.

expandvdisksize

Use the **expand**vdisksize command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expand**volume command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependent**vdisks command to view which volumes go offline if you remove a specific piece of hardware from the system.

lsmetadataavdisk

Use the **lsmetadata**avdisk command to display the information for metadata volume.

lsrepairevdiskcopyprogress

The **lsrepair**evdiskcopyprogress command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappointies

Use the **lsvdiskfcmappointies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsmetatavdisk

Use the **lsmetatavdisk** command to display the information for metadata volume.

Syntax

►► **lsmetatavdisk** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character.

If you enter `-delim :` on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This command displays the information for metadata volume.

This table provides the attribute values that can be displayed as output view data.

Table 132. <i>lsmetadataavdisk</i> output	
Attribute	Description
vdisk_id	Indicates the ID of the metadata volume.
vdisk_name	Indicates the name of the metadata volume.
status	Indicates the running status of the metadata volume.

An invocation example

To display information for a metadata volume:

```
lsmetadataavdisk
```

The resulting output:

```
vdisk_id      2
vdisk_name    vdisk2
status        online
```

On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdisk](#)

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdiskaccess](#)

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyzevdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

[analyzevdiskbysystem](#)

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

[backupvolume](#)

Use the **backupvolume** command to create a volume snapshot.

[backupvolume](#)

Use the **backupvolume** command to create a new snapshot for all of the volumes in a volume group.

[chvdisk](#)

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolume group

Use the **chvolume group** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysis

Use the **lsdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsdiskanalysisprogress

Use the **lsdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsdiskcopy

Use the **lsdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsdiskextent

Use the **lsdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsdiskfcmappcopies

Use the **lsdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsdiskfcmappings

Use the **lsdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumebackupgroup

Use the **mkvolumebackupgroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

Syntax

Parameters

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-copy id

(Optional) Lists the repair progress for the specified copy.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

vdisk_name / vdisk_id

(Optional) Specifies the volume name or ID to list repair progress for. You must specify this parameter last on the command line. If you do not enter this parameter, the command lists progress for all thin-provisioned copies in the clustered system.

Description

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned or compressed copies for the specified volume. If you do not specify a volume, the command lists the repair progress for all thin-provisioned or compressed copies in the clustered system.

Remember: Run this command after you specify the **repairsevdiskcopy** command, which you must run as required by the fix procedures or by your product support information.

The command returns values for the following volume copy attributes:

task

Specifies the active task.

- **repairing** indicates repair of a thin-provisioned volume copy
- **compressed_repairing** indicates repair of a compressed volume copy.

progress

Specifies the task completion percentage.

estimated_completion_time

Specifies the expected duration of the task in the format YYMMDDHHMMSS (or blank if the estimated completion is unknown).

An invocation example

```
lsrepairsevdiskcopyprogress -delim :
```

The resulting output:

```
id:name:copy id:task:progress:estimated_completion_time
0:vdisk0:0:repairing:50:070301120000
0:vdisk0:1:repairing:51:070301120000
1:vdisk1:0:repairing:32:070301153500
```

An invocation example

```
lsrepairsevdiskcopyprogress -delim : vdisk0
```

The resulting output:

```
id:name:copy id:task:progress:estimated_completion_time
0:vdisk0:0:repairing:50:070301120000
0:vdisk0:1:repairing:51:070301120000
```

An invocation example

```
lsrepairsevdiskcopyprogress -delim : -copy 1 vdisk0
```

The resulting output:

```
id:name:copy id:task:progress:estimated_completion_time
0:vdisk0:1:repairing:51:070301120000
```

addvolume[copy](#)

Use the **addvolume**[copy](#) command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdisk[copy](#)

Use the **addvdisk**[copy](#) command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume**[copy](#) command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdisk[access](#)

Use the **addvdisk**[access](#) command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyze[vdisk](#)

Use the **analyze**[vdisk](#) command to queue or cancel volume analysis.

analyze[vdisk](#)[bysystem](#)

Use the **analyze**[vdisk](#)[bysystem](#) command to schedule all existing volumes in system for [available capacity](#) analysis.

backup[volume](#)

Use the **backup**[volume](#) command to create a volume snapshot.

backup[volume](#)[group](#)

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairdiskcopyprogress

Use the **lsrepairdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsdiskaccess

Use the **lsdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysis

Use the **lsdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsdiskanalysisprogress

Use the **lsdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsdiskcopy

Use the **lsdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsdiskextent

Use the **lsdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsdiskfcmapcopies

Use the **lsdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumeegroup

Use the **lsvolumeegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumeegroup

Use the **mkvolumeegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-copy id

(Optional) Specifies the volume copy ID to list repair progress for. If you do not specify this parameter, progress is displayed for all copies.

vdisk_name / vdisk_id

(Optional) Specifies the volume name or ID to list repair progress for. You must specify this parameter last on the command line.

Description

The **lsrepairvdiskcopyprogress** command displays the progress of repairs and validations that are made to mirrored volumes. Use this command to track progress after you run the **repairvdiskcopy** command. You can specify a volume copy by using the **-copy** parameter. To display the volumes that have two or more copies with an active task, specify the command with no parameters; it is not possible to have only one volume copy with an active task.

The command displays progress for the following types of volume copies:

- All volume copies display the same task; validate, medium, or resync, depending on the specified parameter.

- All volume copies display the same percentage and estimated completion time.
- If specified, non-mirrored volumes are displayed as a single copy with a blank task; they are not displayed in the full concise view.
- Once a task completes, the task is blank for all copies.
- If the task is blank, the percentage and the completion time are also blank.

The command returns values for the following volume repair attributes:

vdisk_id

Indicates the volume ID.

vdisk_name

Indicates the volume name.

copy_id

Indicates the system-assigned identifier for the volume copy.

task

Indicates the active task. The values can be `repairing` or `compressed_repairing`.

progress

Indicates the task completion percentage. This value is 0 when task is in `compressed_repairing` state.

estimated_completion_time

Indicates the expected time (duration) the task completion time. The value is in the `YYMMDDHHMMSS` format, and is blank if the duration is not known.

An invocation example

```
lsrepairvdiskcopyprogress -delim :
```

The resulting output:

```
vdisk_id:vdisk_name:copy_id:task:progress:estimated_completion_time
0:vdisk0:0:medium:50:070301120000
0:vdisk0:1:medium:50:070301120000
```

An invocation example

```
lsrepairvdiskcopyprogress -delim : vdisk0
```

The resulting output:

```
vdisk_id:vdisk_name:copy_id:task:progress:estimated_completion_time
0:vdisk0:0:medium:50:070301120000
0:vdisk0:1:medium:50:070301120000
```

An invocation example

```
lsrepairvdiskcopyprogress -delim : -copy 0 vdisk0
```

The resulting output:

```
vdisk_id:vdisk_name:copy_id:task:progress:estimated_completion_time
0:vdisk0:0:medium:50:070301120000
```

An invocation example showing a compressed volume copy and a TP volume copy being repaired

```
lsrepairvdiskcopyprogress
```

The resulting output:

vdisk_id	vdisk_name	copy_id	task	progress	estimated_completion_time
0	vdisk0	0	repairing	50	070301120000
2	vdisk2	1	compressed_repairing	0	070301080102

addvolumecopy

Use the **addvolumecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolumecopy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmmapcopies

Use the **lsvdiskfcmmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data is available to be displayed, headings are not displayed.

-bytes

(Optional) Displays all capacities as bytes. Capacity values that are displayed in units other than bytes might be rounded.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-copy id

(Optional) Specifies the volume copy to list thin-provisioned copies for. You must specify a *vdisk_name* / *vdisk_id* value with this parameter.

-filtervalue?

(Optional) Displays a list of valid filter attributes. The following filters for the **lssevdiskcopy** command are valid:

- *mdisk_grp_id*
- *mdisk_grp_name*
- *overallocation*
- *autoexpand*
- *grainsize*
- *deduplicated_copy*

vdisk_name* / *vdisk_id

(Optional) Specifies the volume name or ID to list thin-provisioned copies for. You must specify this parameter last on the command line. If you do not enter this parameter, the command lists all thin-provisioned copies in the clustered system.

Description

The **lssevdiskcopy** command lists all thin-provisioned copies of the specified volume. If you do not specify a volume, the command lists all thin-provisioned volume copies in the clustered system.

The command provides a concise view of the thin-provisioned properties of the selected volume copies. Run the **lsvdiskcopy** command to see a concise view of the properties that are common to thin-provisioned and non-thin-provisioned volume copies. See the description of the **lsvdisk** command for a description of the fields that are shown in the view.

The command returns values for the following volume copy attributes:

copy_id

Indicates a system-assigned identifier for the volume copy. The value can be 0 or 1.

status

Indicates the system status. The value can be *online* or *offline*. A copy is offline if all nodes cannot access the storage pool that contains the copy.

sync

Indicates whether the volume copy is synchronized.

auto_delete

Indicates that the primary copy is deleted after the secondary copy is synchronized. The values are *yes* or *no*.

primary

Indicates whether the volume copy is the primary copy. A volume has exactly one primary copy. The value can be *yes* or *no*.

mdiskgrp_id

Indicates the ID of the storage pool that the volume copy belongs to.

mdiskgrp_name

Indicates the name of the storage pool that the volume copy belongs to.

type

Indicates the virtualization type of the volume. The value can be striped, sequential, or image.

mdisk_id

Indicates the MDisk ID that is used for sequential and image mode volumes.

mdisk_name

Indicates the MDisk name that is used for sequential and image mode volumes.

fast_write_state

Indicates the cache state of the volume copy. The value can be empty, not_empty, corrupt, or repairing. The value is always empty for non-thin-provisioned copies. A cache state of corrupt indicates that the volume is thin-provisioned and requires repair that is initiated by a **recovervdisk** command or the **repairsevdiskcopy** command.

used_capacity

Indicates the portion of `real_capacity` that is being used to store data. For non-thin-provisioned copies, this value is the same as the volume capacity. If the volume copy is thin-provisioned, the value increases from zero to the `real_capacity` value as more of the volume is written to.

Remember: This field is blank for thin-provisioned and compressed volume copies in a data reduction pool.

real_capacity

Indicates the amount of physical storage that is allocated from a storage pool to this volume copy. If the volume copy is not thin-provisioned, the value is the same as the volume capacity. If the volume copy is thin-provisioned, the value can be different.

Remember: This field is blank for thin-provisioned and compressed volume copies in a data reduction pool.

free_capacity

Indicates the difference between the `real_capacity` and `used_capacity` values.

Remember: This field is blank for thin-provisioned and compressed volume copies in a data reduction pool.

overalllocation

Expressed as a percentage, indicates the ratio of volume capacity to `real_capacity` values. This value is always 100 for non-thin-provisioned volumes.

Remember: This field is zero for thin-provisioned and compressed volume copies in a data reduction pool.

autoexpand

Indicates whether autoexpand is enabled on a thin-provisioned volume. The value can be on or off.

warning

Expressed as a percentage, for thin-provisioned volume copies only, indicates that a warning is generated when the ratio of `used_capacity` to volume capacity reaches the specified level.

Remember: This field is zero for thin-provisioned and compressed volume copies in a data reduction pool.

grainsize

For thin-provisioned volume copies, indicates the grain size that is chosen for the volume copy when it was created.

Remember: This field is blank for compressed volume copies in regular storage pools.

se_copy

Indicates whether the copy is thin-provisioned. The value can be yes or no.

easy_tier

Indicates whether Easy Tier is permitted to manage the pool.

Note:

1. If `easy_tier` is on, then `easy_tier_status` can take on any value.

2. If `easy_tier` is `off`, then `easy_tier_status` is `measured` or `inactive`.

easy_tier_status

Indicates which Easy Tier functions are active for the volume copy:

- `active` indicates that a pool is being managed by Easy Tier to provide tier management performance-based pool balancing. For example, extents of this volume copy can be moved for performance (automatic data placement).
- `inactive` indicates that no Easy Tier function is active.
- `measured` indicates that statistics are being gathered for this volume copy, but no extents are moved.
- `balanced` indicates that a pool is being managed by Easy Tier to provide performance-based pool balancing (for example, extents can be moved).

This table describes the storage pool Easy Tier settings.

<i>Table 133. Easy Tier settings for storage pools and volumes</i>			
Storage pool Easy Tier setting	Number of tiers in the storage pool	Volume copy Easy Tier setting	Volume copy Easy Tier status
Off	One	Off	inactive (see note “1” on page 1619)
Off	One	On	inactive (see note “1” on page 1619)
Off	Two	Off	inactive (see note “1” on page 1619)
Off	Two	On	inactive (see note “1” on page 1619)
Measure	One	Off	measured (see note “2” on page 1619)
Measure	One	On	measured (see note “2” on page 1619)
Measure	Two	Off	measured (see note “2” on page 1619)
Measure	Two	On	measured (see note “2” on page 1619)
Auto	One	Off	measured (see note “2” on page 1619)
Auto	One	On	balanced (see note “3” on page 1619)
Auto	Two	Off	active (see note “4” on page 1619)
Auto	Two	On	measured (see note “2” on page 1619)
On	One	Off	measured (see note “2” on page 1619)
On	One	On	balanced (see note “3” on page 1619)
On	Two	Off	measured (see note “2” on page 1619)

Table 133. Easy Tier settings for storage pools and volumes (continued)

Storage pool Easy Tier setting	Number of tiers in the storage pool	Volume copy Easy Tier setting	Volume copy Easy Tier status
On	Two	On	active (see note “4” on page 1619)

Note:

1. When the volume copy status is inactive, no Easy Tier functions are enabled for that volume copy.
2. When the volume copy status is measured, the Easy Tier function collects usage statistics for the volume but automatic data placement is not active.
3. When the volume copy status is balanced, the Easy Tier function enables performance-based pool balancing for that volume copy.
4. When the volume copy status is active, the Easy Tier function operates in automatic data placement mode for that volume.

If the volume copy is in image or sequential mode or is being migrated, the volume copy Easy Tier status is measured instead of active.

The default Easy Tier setting for a storage pool is auto, and the default Easy Tier setting for a volume copy is on. These settings mean that Easy Tier functions except pool performance balancing are disabled for storage pools with a single tier, and that automatic data placement mode is enabled for all striped volume copies in a storage pool with two or more tiers.

tier

Indicates which tier information is being reported:

- tier0_flash
- tier1_flash
- tier_enterprise
- tier_nearline
- tier_scm

tier_capacity

Indicates the total MDisk capacity that is assigned to the volume in the tier.

Note: For thin-provisioned copies, the capacity by tier is the real capacity.

compressed_copy

Indicates whether the volume copy is compressed.

uncompressed_used_capacity

For compressed volume copies, indicates the amount of data that is written to the volume copy before compression. This field is blank for volume copies in a data reduction storage pool.

used_capacity_before_reduction

Indicates the total amount of data that is written to a thin-provisioned or compressed volume copy in a data reduction storage pool before data reduction occurs. This field is blank for fully allocated volume copies and volume copies not in a data reduction pool.

parent_mdisk_grp_id

Indicates the physical storage pool ID that the volume extents are allocated from. This value is a numeric string (in the range 0 - 127 characters) or blank.

parent_mdisk_grp_name

Indicates the physical storage pool name that the volume extents are allocated from. This value is an alphanumeric string (in the range 1 - 63 characters) or blank.

encrypt

Indicates whether the volume and its copies are encrypted. The values are yes or no.

deduplicated_copy_count

Indicates the number of data deduplicated volume copies.

deduplicated_copy

Indicates whether the volume copy is data deduplicated. The values are:

- yes
- no

An invocation example

```
lssevdiskcopy -delim :
```

The following output is displayed:

```
vdisk_id:vdisk_name:copy_id:mdisk_grp_id:mdisk_grp_name:capacity:used_capacity:real

```

Related reference

[addvolumecopy](#)

Use the **addvolumecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdiskcopy](#)

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolume**group command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolume**group command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisk** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdisk**map command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavd**isk command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdisk**copyprogress command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdisk**copyprogress command to display the progress of volume repairs and validations.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdisk**access command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdisk**analysis command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability

volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to remove a volume backup from a system.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskspace

Use the **splitvdiskspace** command to create a separate volume from a synchronized copy of a mirrored volume.

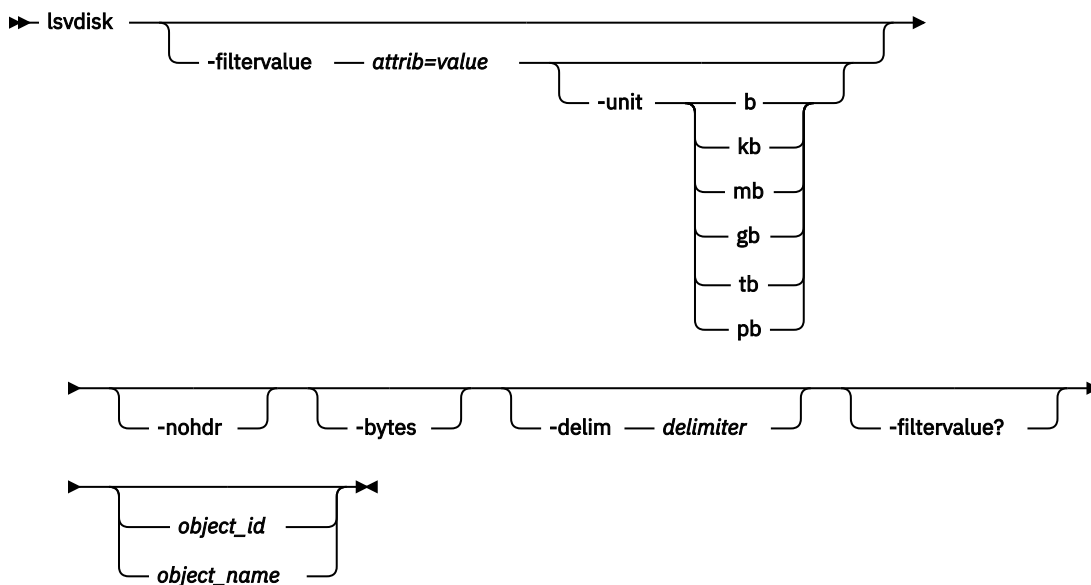

splitvdiskspace

Use the **splitvdiskspace** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

Syntax

Parameters

-filtervalue attrib=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed. If a capacity is specified, the units must also be included.

-unit b | kb | mb | gb | tb | pb

(Optional) Specifies the data units for the **-filtervalue** parameter.

Note: **-unit** must be used with **-filtervalue**.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-bytes

(Optional) Displays all capacities as bytes. Capacity values that are displayed in units other than bytes might be rounded. When you filter a capacity value, use a unit of bytes, **-unit b**, for exact filtering. For thin-provisioned copies, the capacity by tier contains the real capacities.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue?

Displays a list of valid filter attributes. The following filters for the **lsvdisk** command are valid:

- access_IO_group_count
- backup_status
- capacity
- cloud_backup_enabled
- cloud_account_id
- cloud_account_name
- compressed_copy_count
- copy_count
- deduplicated_copy_count
- fast_write_state
- FC_id
- fc_map_count
- FC_name
- filesystem
- function
- id
- IO_group_id
- IO_group_name
- mdisk_grp_name
- mdisk_grp_id
- mirror_write_priority
- name
- owner_type
- owner_id
- owner_name
- preferred_node_id
- RC_change

- RC_id
- RC_name
- restore_status
- se_copy_count
- status
- type
- vdisk_UID
- volume_group_id
- volume_group_name
- volume_id
- volume_name
- protocol

Note: It is not possible to filter the **lsvdisk** command with `mdisk_grp_name=many` to identify mirrored volumes. Instead, filter on `copy_count=2`.

object_id / object_name

(Optional) Specifies the name or ID of an object. When you use this parameter, the detailed view of the specific object is returned and any value that is specified by the **-filtervalue** parameter is ignored. If you do not specify the *object_id / object_name* parameter, the concise view of all objects that match the filtering requirements that are specified by the **-filtervalue** parameter are displayed.

Description

This command displays a concise list or a detailed view of attributes for all volumes and volume copies in the system.

The volume is offline and unavailable if one of the following actions takes place:

- Both nodes in the I/O group are missing.
- None of the nodes in the I/O group that are present can access the volume.
- All synchronized copies for this volume are in storage pools that are offline.
- The volume is formatting.

If you have a degraded volume and all of the associated nodes and MDisk are online, refer to your product support information for assistance. A volume is reported as degraded if any of the following occurs:

- One of the nodes in the I/O group is missing.
- One of the nodes in the I/O group cannot access all the MDisk in the storage pool that the volume spans. In this case, MDisk are shown as degraded and the fix procedures for MDisk must be followed to resolve the problem.
- The fast write cache pins data for one or more volumes in the I/O group and is unable to perform a fallback until the situation is resolved. An error log indicating that the cache contains pinned data is displayed. Follow the fix procedures for this event log to resolve the problem. The following situations are the most common causes of pinned data:
 - One or more volumes in an I/O group is offline due to an asymmetric failure and contains pinned data in the cache. Asymmetric failures can occur because of fabric faults or misconfiguration, back-end controller faults or misconfiguration, or because repeated errors cause the system to exclude access to a MDisk through one or more nodes.
 - One or more volumes in an I/O group is offline due to a problem with a FlashCopy mapping.
 - A thin-provisioned disk runs out of space.

You can encrypt volumes and volume copies. The volume is encrypted if all volume copies are also encrypted.

Note: This means that during a migration of a volume (with one copy) between an encrypted and unencrypted storage pool the value is no.

The volume is not encrypted if the storage pool has a value of `encrypt : no`, including if the volume's extents are part of an encrypted MDisk or sequential volume.

The command returns values for the following volume attributes:

IO_groups_id

Indicates the I/O group (ID) that the volume belongs to.

IO_groups_name

Indicates the I/O group (name) that the volume belongs to.

status

Indicates the status. The value can be `online`, `offline`, `degraded`, or `deleting`.

For online HyperSwap volumes the scope of offline copy is included with the status information. For offline volumes the auxiliary copy is included with the status information even if the copy associated with that is online.

mdisk_grp_id

Indicates the ID of the storage pool that the volume belongs to. If the volume has more than one copy, these fields display many.

mdisk_grp_name

Indicates the name of the storage pool that the volume belongs to. If the volume has more than one copy, these fields display many.

type

Indicates the virtualization type of the volume. The value can be `striped`, `seq`, `image` or `many`. The value `many` indicates that the volume has more than one copy, which can have different virtualization types.

capacity

Indicates the provisioned capacity of the volume that is the size of the volume as seen by the host.

formatted

Indicates whether the volume was formatted when it was created. The value can be `yes` or `no`.

formatting

Indicates whether the volume is formatting. The value can be `yes` or `no`.

mdisk_id

Indicates the MDisk ID that is used for sequential and image mode volumes. If the volume has more than one copy, these fields display many.

mdisk_name

Indicates the MDisk name that is used for sequential and image mode volumes. If the volume has more than one copy, these fields display many.

FC_id

Indicates the ID of the FlashCopy mapping that the volume belongs to. The value `many` indicates that the volume belongs to more than one FlashCopy mapping.

FC_name

Indicates the name of the FlashCopy mapping that the volume belongs to. The value `many` indicates that the volume belongs to more than one FlashCopy mapping.

RC_id

Indicates the ID of the remote copy relationship that the volume belongs to. The value must be numerical.

RC_name

Indicates the name of the remote copy relationship that the volume belongs to.

vdisk_UID

Indicates the UID of the volume. If a volume is mapped to a host using the NVMe protocol, then the vdisk_UID value shows the Namespace Globally Unique Identifier (NGUID) for the volume.

throttle_ID

Indicates the ID for the throttle object. The value is a numeric string in the range 0 - 10241 (or is blank if no throttle is configured).

throttle_name

Indicates the name of the throttle object. The value is an alphanumeric string in the range 1 - 63 characters or blank if no throttle is specified.

IOPs_limit

Indicates the IOPs limit that is configured for the volume. The value is a numeric string or blank if no limit is specified.

bandwidth_limit_MB

Indicates the bandwidth limit configured (in MB) for the volume. The value is a numeric string or is blank if no limit is configured.

preferred_node_id

Indicates the node that processes the I/O data.

Remember: This value must be numeric. (The value is zero if no node is configured in the I/O group that contains the preferred node.)

fast_write_state

Indicates the cache state for the volume or volume copy. The value can be empty, not_empty, corrupt, or repairing. A cache state of corrupt indicates that the volume or volume copy requires repairing or recovery by using either the **recovervdisk** or **repairvdiskcopy** command.

cache

Indicates the cache mode of the volume. The value can be readonly, readwrite, or none.

udid

Indicates the unit number for the volume. Only OpenVMS hosts require a unit number.

fc_map_count

Indicates the number of FlashCopy mappings that the volume belongs to.

sync_rate

Indicates the rate for synchronization for mirrored copies.

se_copy_count

Indicates the number of thin-provisioned copies.

Remember: This value represents only thin-provisioned copies and is not used for compressed volume copies.

filesystem

Expressed as a value string (long object name with a maximum of 63 characters), indicates the full name for file system that owns this volume; otherwise, it is blank.

mirror_write_priority

Indicates the mirror write algorithm priority that is used if the volume is mirrored.

RC_change

Indicates whether a volume is a change volume of a remote copy relationship.

compressed_copy_count

Indicates the number of compressed volume copies.

access_IO_group_count

Indicates the number of I/O groups in the volume access set.

protocol

Indicates the protocol that must be used by the hosts that are mapping this volume. The protocol is associated with the volume through existing mappings to hosts. The protocol is inherited from the protocol of the first host the volume is mapped to. If the volume is not mapped to any host, the value

is blank. If the volume is unmapped from all hosts, the value becomes blank again. The possible values are **scsi**, **nvme**, or blank.

owner_id

Displays the ID of the ownership group.

owner_name

Displays the name of the ownership group.

The command returns values for the following volume copy attributes:

copy_id

Indicates a system-assigned identifier for the volume copy. The value can be 0 or 1.

status

Indicates the status. The value can be online, offline, degraded, or deleting.

sync

Indicates whether the volume copy is synchronized.

auto_delete

Indicates that the primary copy is deleted after the secondary copy is synchronized. The values are yes or no.

primary

Indicates whether the volume copy is the primary copy. A volume has exactly one primary copy. The value can be Yes or No.

mdiskgrp_id

Indicates the ID of the storage pool that the volume copy belongs to.

mdiskgrp_name

Indicates the name of the storage pool that the volume copy belongs to.

type

Indicates the virtualization type of the volume. The value can be striped, seq, or image.

mdisk_id

Indicates the MDisk ID that is used for sequential and image mode volumes.

mdisk_name

Indicates the MDisk name that is used for sequential and image mode volumes.

used_capacity

Indicates the portion of `real_capacity` that is being used to store data. For non-thin-provisioned copies, this value is the same as the volume capacity. If the volume copy is thin-provisioned, the value increases from zero to the `real_capacity` value as more of the volume is written to. This field is blank for volume copies that are thin-provisioned or compressed volume copies in a data reduction pool.

real_capacity

Indicates the amount of physical storage that is allocated from a storage pool to this volume copy. If the volume copy is not thin-provisioned, the value is the same as the volume capacity. If the volume copy is thin-provisioned, the value can be different. This field is blank for volume copies that are thin-provisioned or compressed volume copies in a data reduction pool.

free_capacity

Indicates the difference between the `real_capacity` and `used_capacity` values. This field is blank for storage pools that are not thin-provisioned or compressed volume copies in a data reduction pool.

overallocation

Expressed as a percentage of the volume capacity, indicates the ratio of capacity to `real_capacity` values. This value is always 100 for non-thin-provisioned or compressed volumes.

Remember:

- This field is blank for volume copies that are thin-provisioned or compressed volume copies in a data reduction pool.

- This value cannot be blank for compressed volume copies.

This field is blank for volume copies that are thin-provisioned or compressed volume copies in a data reduction pool.

autoexpand

Indicates whether **autoexpand** is enabled on a thin-provisioned volume. The value can be on or off.

Remember: This value cannot be blank for compressed copies.

warning

Expressed as a percentage of the volume capacity, this value indicates a warning for thin-provisioned or compressed volume copies. A warning is generated when the ratio of used_capacity to volume capacity reaches the specified level.

Remember:

- This field is blank for volume copies that are thin-provisioned or compressed volume copies in a data reduction pool.
- This value cannot be blank for compressed volume copies.

grainsize

For thin-provisioned volume copies, indicates the grain size that is chosen for the volume copy when it was created.

Remember: This value is always blank for compressed volume copies in regular storage pools.

se_copy

Indicates whether the copy is thin-provisioned.

Remember: This value is yes for thin-provisioned copies and no for compressed volume copies.

easy_tier

This value is set by the user and indicates whether Easy Tier is permitted to manage the pool.

Note:

1. If easy_tier is on, then easy_tier_status can take on any value.
2. If easy_tier is off, then easy_tier_status is measured or inactive.

easy_tier_status

Indicates which Easy Tier functions are active for the volume copy:

- active indicates that a pool is being managed by Easy Tier to provide tier management performance-based pool balancing. For example, extents of this volume copy can be moved for performance (automatic data placement).
- inactive indicates that no Easy Tier function is active.
- measured indicates that statistics are being gathered for this volume copy, but no extents are moved.
- balanced indicates that a pool is being managed by Easy Tier to provide performance-based pool balancing (for example, extents can be moved).

This table displays possible values and related information for easy_tier_status:

Table 134. Easy Tier status values. Easy Tier status values			
Storage pool Easy Tier setting	Number of tiers in the storage pool	Volume copy Easy Tier setting	Volume copy Easy Tier status
Off	One	Off	inactive (see note “1” on page 1632)
Off	One	On	inactive (see note “1” on page 1632)

Table 134. Easy Tier status values. Easy Tier status values (continued)			
Storage pool Easy Tier setting	Number of tiers in the storage pool	Volume copy Easy Tier setting	Volume copy Easy Tier status
Off	Two	Off	inactive (see note “1” on page 1632)
Off	Two	On	inactive (see note “1” on page 1632)
Measure	One	Off	measured (see note “2” on page 1632)
Measure	One	On	measured (see note “2” on page 1632)
Measure	Two	Off	measured (see note “2” on page 1632)
Measure	Two	On	measured (see note “2” on page 1632)
Auto	One	Off	measured (see note “2” on page 1632)
Auto	One	On	balanced (see note “3” on page 1632)
Auto	Two	Off	measured (see note “2” on page 1632)
Auto	Two	On	(see note “4” on page 1632)
On	One	Off	measured (see note “2” on page 1632)
On	One	On	balanced (see note “3” on page 1632)
On	Two	Off	measured (see note “2” on page 1632)
On	Two	On	active (see note “4” on page 1632)
Notes: <ol style="list-style-type: none"> 1. When the volume copy status is inactive, no Easy Tier functions are enabled for that volume copy. 2. When the volume copy status is measured, the Easy Tier function collects usage statistics for the volume but automatic data placement is not active. 3. When the volume copy status is balanced, the Easy Tier function enables performance-based pool balancing for that volume copy. 4. When the volume copy status is active, the Easy Tier function operates in automatic data placement mode for that volume. 			

If the volume copy is in image or sequential mode or is being migrated, the volume copy Easy Tier status is measured instead of active.

The default Easy Tier setting for a storage pool is auto, and the default Easy Tier setting for a volume copy is on. This means that Easy Tier functions except pool performance balancing are disabled for storage pools with a single tier, and that automatic data placement mode are enabled for all striped volume copies in a storage pool with two or more tiers.

tier

The tier information being reported:

- tier0_flash
- tier1_flash
- tier_enterprise
- tier_nearline
- tier_scm

tier_capacity

The total MDisk capacity that is assigned to the volume in the tier.

Note: For thin-provisioned copies, the capacity by tier is the real capacity.

compressed_copy

Indicates whether the volume copy is compressed.

uncompressed_used_capacity

For compressed volume copies, indicates the amount of data written to the volume copy before compression. This field is blank for volume copies in a data reduction storage pool.

used_capacity_before_reduction

Indicates the total amount of data written to a thin-provisioned or compressed volume copy in a data reduction storage pool before data reduction occurs. This field is blank for fully allocated volume copies and volume copies not in a data reduction pool.

last_access_time

Indicates the time (YYMMDDHHMMSS) the volume last received Small Computer System Interface (SCSI) commands from any mapped host.

parent_mdisk_grp_id

Indicates the physical storage pool ID that the volume extents are allocated from. This value is a numeric string (in the range 0 - 127 characters) or blank.

parent_mdisk_grp_name

Indicates the physical storage pool name that the volume extents are allocated from. This value is an alphanumeric string (in the range 1 - 63 characters) or blank.

owner_type

Indicates the type of owning component or object (such as a file system). The values are:

- filesystem
- host_integration_metadata
- vvol
- none

The value is none if no owner is assigned.

owner_id

Indicates an identification number for the owning object. This value must be a numeric character unless there is no owning object (in which case it is blank).

owner_name

Indicates the name for owning object that owns this volume. The value must be a set of up to 63 alphanumeric characters, but is blank if there is no owning object.

encrypt

Indicates whether all copies of a volume reside in MDisk groups (storage pools) that are reported as encrypting. This means that either one of the following things apply:

- The copies reside in a storage pool that has an encryption key.
- All MDisk in the group are self-encrypting or encrypted for RAID.

The values are yes and no.

volume_id

Indicates the volume ID (for a high availability volume). This ID must be a numerical value. For a basic or stretched volume, volume_ID has the same value as id. For a HyperSwap volume (involved in an active-active relationship), the volume ID is the same as the master volume.

volume_name

Indicates the volume name (for a high availability volume). This value must be an alphanumeric string that contains up to 63 characters. For a basic or stretched volume, volume_name has the same value as name. For a HyperSwap volume (involved in an active-active relationship), the volume name is the same as the master volume.

function

Indicates the function of the volume in the remote copy relationship. Remote copy includes Metro Mirror, Global Mirror, and HyperSwap.

The values are:

- master, which indicates a master volume in a remote copy relationship.
- aux, which indicates an auxiliary volume in a remote copy relationship.
- master_change, which indicates a change volume for a master volume in a remote copy relationship.
- aux_change, which indicates a change volume for an auxiliary volume in a remote copy relationship.
- Blank, which indicates that the volume is not in any remote copy relationship.

volume_group_id

Indicates a volume group ID for a volume group that a volume belongs to. The value must be a number.

volume_group_name

Indicates the volume group name for a volume group that a volume belongs to. The value must be an alphanumeric string.

cloud_backup_enabled

Indicates whether the cloud snapshot feature is enabled for the specified volume. The values are yes or no.

cloud_account_id

Indicates the cloud account ID. The value must be a number.

cloud_account_name

Indicates the cloud account name. The value must be an alphanumeric string.

backup_status

Indicates whether a new cloud snapshot can be started. If a backup is in progress, the status of the backup operation is given. The values are:

- off
- ready
- copying
- copying_error
- not_ready

last_backup_time

Indicates the time of the most recent backup or snapshot for the specified volume. The value must be in YYMMDDHHMMSS format (or blank).

restore_status

Indicates whether a restore can be performed for the volume. If a restore is in progress, the status of the restore operation is given. The values are:

- none
- available

- restoring
- restoring_error
- committed
- committing
- committing_error

backup_grain_size

Indicates the grain size for the volume mappings that are used for the cloud snapshot function. The value is blank if cloud snapshot is not enabled.

Note: This sizing does not reflect the size of the grains that are stored in the cloud (which are fixed at 256 KB).

deduplicated_copy_count

Indicates the number of data deduplicated volume copies.

deduplicated_copy

Indicates whether the volume copy is data deduplicated. The values are:

- yes
- no

owner_id

Displays the ID of the ownership group.

owner_name

Displays the name of the ownership group.

A detailed invocation example for a volume

```
lsvdisk -delim : vv45
```

A detailed invocation example for a new style volume

```
lsvdisk -delim : Volume0
```

The following output is displayed:

```
id 0
name Volume0
...
deduplicated_copy_count 1
copy_id 0
...
deduplicated_copy yes
```

Related reference

[addvolume](#)[copy](#)

Use the **addvolume****copy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdisk](#)[copy](#)

Use the **addvdisk****copy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume****copy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdisk](#)[access](#)

Use the **addvdisk****access** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyze](#)[vdisk](#)

Use the **analyze****vdisk** command to queue or cancel volume analysis.

[analyze](#)[vdisk](#)[by](#)[system](#)

Use the **analyze****vdisk****by****system** command to schedule all existing volumes in system for [available capacity](#) analysis.

[backup](#)[volume](#)

Use the **backup****volume** command to create a volume snapshot.

[backup](#)[volume](#)[group](#)

Use the **backup****volume****group** command to create a new snapshot for all of the volumes in a volume group.

[ch](#)[vdisk](#)

Use the **ch****vdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

[ch](#)[volume](#)[group](#)

Use the **chvolume** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysis

Use the **lsdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsdiskanalysisprogress

Use the **lsdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsdiskcopy

Use the **lsdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsdiskextent

Use the **lsdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsdiskfcmappcopies

Use the **lsdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsdiskfcmappings

Use the **lsdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsdiskhostmap

Use the **lsdiskhostmap** command to list the hosts to which a volume is mapped.

lsdisklba

Use the **lsdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

[lsvdiskprogress](#)

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

[lsdisksyncprogress](#)

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

[lsvolumebackup](#)

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

[lsvolumebackupgeneration](#)

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

[lsvolumebackupprogress](#)

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

[lsvolumebackupgroup](#)

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

[lsvolumebackuprestoreprogress](#)

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

[mkmetadavdisk](#)

Use the **mkmetadavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

[mkvdisk](#)

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

[mkvdiskhostmap](#)

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

[mkvolume](#)

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

[mkvolumebackupgroup](#)

Use the **mkvolumebackupgroup** command to create and configure a new volume group.

[mkimagevolume](#)

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

[movevdisk](#)

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

[recovervdisk](#)

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

[recovervdiskbycluster](#) (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

[recovervdiskbyiogrp](#)

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

[recovervdiskbysystem](#)

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

[repairsevdiskcopy](#)

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

[repairvdiskcopy](#)

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

[restorevolume](#)

Use the **restorevolume** command to restore a volume from a snapshot generation.

[rmvdisk](#)

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

[rmmetadatavdisk](#)

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

[rmvdiskcopy](#)

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

[rmvdiskaccess](#)

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

[rmvdiskhostmap](#)

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

[rmvolume](#)

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeecopy](#)

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumegroup](#)

Use the **rmvolumegroup** command to remove a volume group from a system.

[rmvolumebackupgeneration](#)

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (""):
`lsvdiskaccess -filtervalue "IO_group_name=io*"`

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue?

(Optional) Displays the valid filter attributes for the **-filtervalue** parameter:

- IO_group_id
- IO_group_name

vdisk_id / vdisk_name

(Optional) Specifies the volume for which to list access I/O groups.

Description

The **lsvdiskaccess** command lists the I/O groups in a volume access set. An accessible volume in an I/O group does not indicate that the volume is mapped to any hosts. There is a detailed view and concise view, but the detailed view does not contain more information than the concise view.

This command returns values for the following volume attributes:

VDisk_id

Identifies the volume ID.

VDisk_name

Identifies the volume name.

IO_group_id

Identifies an I/O group ID in the volume access set.

IO_group_name

Identifies an I/O group name in the volume access set.

A detailed invocation example

```
lsvdiskaccess 0
```

The resulting output:

vdisk_id	vdisk_name	IO_group_id	IO_group_name
0	vdisk0	0	io_grp0
0	vdisk0	1	io_grp1
0	vdisk0	2	io_grp2

A concise invocation example

```
lsvdiskaccess
```

The resulting output:

vdisk_id	vdisk_name	IO_group_id	IO_group_name
0	vdisk0	0	io_grp0
0	vdisk0	1	io_grp1
0	vdisk0	2	io_grp2
3	vdisk3	1	io_grp1
7	vdisk7	0	io_grp0
7	vdisk7	2	io_grp2
