Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumegroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

Syntax

Parameters

-nohdr

By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data is displayed, headings are not displayed.

-delim delimiter

By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue attribute=value

Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards with the CLI:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (" ").

```
lsvdiskanalysis -filtervalue "usergrp_name=md★"
```

-filtervalue?

Displays the valid filter attributes for the **-filtervalue attribute=value** parameter:

- id
- name
- state

vdisk_id / vdisk_name

Specifies the volume (by ID or name) to display compression estimation status for.

Description

This command displays information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

This table provides the attribute values that can be displayed as output view data.

<i>Table 135. Output from the lsvdiskanalysis command</i>	
Attribute	Description
id	Indicates the ID (by number) of the object.
analysis_state	Indicates one of the following values: <ul style="list-style-type: none"> • idle Indicates that the volume was never analyzed. • scheduled Indicates that the volume is scheduled for analysis (the analysis starts based on ascending volume IDs). • active Indicates that the volume is being analyzed. • estimated Indicates that the volume was analyzed and the analysis results reflect the estimated savings from thin provisioning and compression. • sparse Indicates that the volume was analyzed but not enough samples of nonzero data were found. • cancelling Indicates that the analysis is ongoing and a request exists to cancel the analysis, but the analysis is not yet ended.
started_time	Indicates the date and time that the analysis started, which helps determine how long an estimate takes. The value must be an alphanumeric data string or be empty if analysis never started.
analysis_time	Indicates the date and time that the analysis ends to help determine how current the results are. If you cancel analysis, the value for the time is invalid (0, and it is not displayed). While active, time is invalid as well and does not reflect expected completion time. The value must be an alphanumeric data string or be empty if analysis never occurred.
capacity	Indicates the provisioned capacity (host size) of the volume.
thin_size	Indicates the estimated size of the data without zero portions (thin-provisioned size).
thin_savings	Indicates how much data is expected to be saved if it is a thin-provisioned volume.
thin_savings_ratio	Indicates the percent of data that is saved by thin-provisioned. The number must be a percentage.
compressed_size	Indicates the estimated size of any nonzero data after compression completes.
compression_savings	Indicates how much data to expect to save if the volume is a compressed volume.
compression_savings_ratio	Indicates the amount of data that is saved by compression. The number must be a percentage.
total_savings	Indicates how much data to expect to save by converting a volume to a compressed volume.

Table 135. Output from the **lsvdiskanalysis** command (continued)

Attribute	Description
total_savings_ratio	Indicates the amount of data that is saved by compression based on the overall volume capacity, which includes the thin nature of compressed volumes. The number must be a percentage.
accuracy	Indicates the accuracy estimation. The number must be a percentage.

A concise invocation example

```
lsvdiskanalysis
```

The detailed resulting output

```
id name state analysis_time capacity thin_size thin_savings thin_savings_ratio compressed_size compression_savings compression_savings_ratio
total_savings total_savings_ratio accuracy
0 ben0 idle 0 1.00GB 0.00MB 0.00MB 0 0.00MB 0.00MB 0

Related reference

[addvolume](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdisk](#)

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdiskaccess](#)

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysisprogress

Use the **lsdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappointies

Use the **lsvdiskfcmappointies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolume group

Use the **mkvolume group** command to create and configure a new volume group.

mkimage volume

Use the **mkimage volume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume copy

Use the **rmvolume** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolume** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

Syntax

➤ **lsvdiskanalysisprogress** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

Description

This command displays information about the space analysis progress for an entire system.

This table provides the attribute values that can be displayed as output view data.

Table 136. <i>lsvdiskanalysisprogress</i> output	
Attribute	Description
vdisk_count	Indicates the number of volumes on this system.
pending_analysis	Indicates the number of volumes that belong to this system and: <ul style="list-style-type: none">• Scheduled a available capacity analysis• Have an active available capacity analysis• Are canceling available capacity analysis

Table 136. *lsvdiskanalysisprogress* output (continued)

Attribute	Description
estimated_completion_time	Indicates the estimated time at which analysis is expected to end. It is calculated based on number of scheduled volumes that are multiplied by 1 minute (there is no extrapolation from actual analysis duration). Estimated completion time does not consider volumes that are offline and displays estimated completion time as if the volumes are online.

A concise invocation example that shows progress for a system with some scheduled disks

```
lsvdiskanalysisprogress
```

The detailed resulting output:

```
vdisk_count pending_analysis estimated_completion_time
15          10              20150523135200
```

A concise invocation example that shows progress for a system with no scheduled disks

```
lsvdiskanalysisprogress
```

The detailed resulting output:

```
vdisk_count pending_analysis estimated_completion_time
15          0
```

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyzevdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

[analyzevdiskbysystem](#)

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

[backupvolume](#)

Use the **backupvolume** command to create a volume snapshot.

[backupvolumegroup](#)

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

[chvdisk](#)

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

[chvolumegroup](#)

Use the **chvolume** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsdiskaccess

Use the **lsdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysis

Use the **lsdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsdiskcopy

Use the **lsdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsdiskextent

Use the **lsdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsdiskfcmappcopies

Use the **lsdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsdiskfcmappings

Use the **lsdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsdiskhostmap

Use the **lsdiskhostmap** command to list the hosts to which a volume is mapped.

lsdisklba

Use the **lsdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadavdisk

Use the **mkmetadavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumebackupgroup

Use the **mkvolumebackupgroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

[recovervdiskbyiogrp](#)

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

[recovervdiskbysystem](#)

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

[repairsevdiskcopy](#)

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

[repairvdiskcopy](#)

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

[restorevolume](#)

Use the **restorevolume** command to restore a volume from a snapshot generation.

[rmvdisk](#)

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

[rmmetadatavdisk](#)

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

[rmvdiskcopy](#)

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

[rmvdiskaccess](#)

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

[rmvdiskhostmap](#)

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

[rmvolume](#)

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeecopy](#)

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumegroup](#)

Use the **rmvolumegroup** command to remove a volume group from a system.

[rmvolumebackupgeneration](#)

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

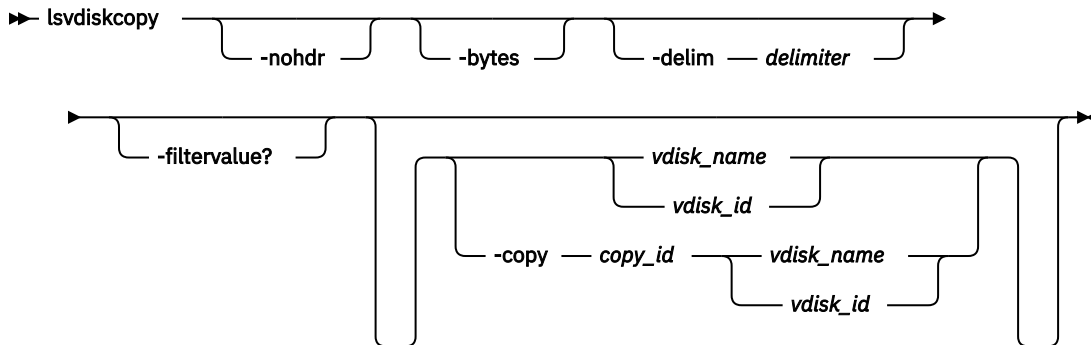

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

Syntax

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data exists to be displayed, headings are not displayed.

-bytes

(Optional) Displays all capacities as bytes. Capacity values that are displayed in units other than bytes might be rounded.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-copy copy_id

(Optional) Specifies the volume copy to list information for. You must specify a *vdisk_name* / *vdisk_id* value with this parameter.

-filtervalue?

(Optional) Displays a list of valid filter attributes. The following filters for the **lsvdiskcopy** command are valid:

- primary
- status
- sync
- mdisk_grp_id
- mdisk_grp_name
- type
- easy_tier
- easy_tier_status

- deduplicated_copy

vdisk_name / vdisk_id

(Optional) Specifies the volume to list copy information for. You must specify this parameter last on the command line. If you specify a *vdisk_name / vdisk_id* value only, all copies for the volume are listed.

Description

The **lsvdiskcopy** command lists information for volume copies. If you specify the command with no parameters, all volumes and copies in the clustered system are listed.

The command returns values for the following volume copy attributes:

copy_id

Specifies a system-assigned identifier for the volume copy. The value can be 0 or 1.

status

Indicates the status. The value can be online, offline, or deleting. A copy is offline if all nodes cannot access the storage pool that contains the copy.

sync

Indicates whether the volume copy is synchronized.

auto_delete

Indicates that the primary copy is deleted after the secondary copy is synchronized. The values are yes or no.

primary

Indicates whether the volume copy is the primary copy. A volume has exactly one primary copy. The value can be yes or no.

mdiskgrp_id

Indicates the ID of the storage pool that the volume copy belongs to.

mdiskgrp_name

Indicates the name of the storage pool that the volume copy belongs to.

type

Indicates the virtualization type of the volume. The value can be striped, sequential, or image.

mdisk_id

Indicates the MDisk ID that is used for sequential and image mode volumes.

mdisk_name

Indicates the MDisk name that is used for sequential and image mode volumes.

fast_write_state

Indicates the cache state of the volume copy. The value can be empty, not_empty, corrupt, or repairing. The value is always empty for non-thin-provisioned copies. A cache state of corrupt indicates that the volume is thin-provisioned and requires repair that is initiated by a **recovervdisk** command or the **repairsevdiskcopy** command.

used_capacity

Indicates the portion of *real_capacity* that is being used to store data. For non-thin-provisioned copies, this value is the same as the volume capacity. If the volume copy is thin-provisioned, the value increases from zero to the *real_capacity* value as more of the volume is written to.

Remember:

- This value is the same as the volume capacity value for [standard-provisioned](#) copies.
- This field is blank for volume copies that are thin-provisioned or compressed volume copies in a data reduction pool.

real_capacity

Indicates the amount of physical storage that is allocated from a storage pool to this volume copy. If the volume copy is not thin-provisioned, the value is the same as the volume capacity. If the volume copy is thin-provisioned, the value can be different.

Remember:

- This value is the same as the volume capacity value for [standard-provisioned](#) copies.
- This field is blank for volume copies that are thin-provisioned or compressed volume copies in a data reduction pool.

free_capacity

Indicates the difference between the `real_capacity` and `used_capacity` values.

Remember:

- This value is 0 for [standard-provisioned](#) copies.
- This field is blank for volume copies that are thin-provisioned or compressed volume copies in a data reduction pool.

Remember: This value is zero for [standard-provisioned](#) copies.

overallallocation

Expressed as a percentage, indicates the ratio of volume capacity to `real_capacity` values. This value is always 100 for non-thin-provisioned volumes.

Remember: This field is blank for storage pools that are not thin-provisioned or compressed volume copies in a data reduction pool.

autoexpand

Indicates whether `autoexpand` is enabled on a thin-provisioned volume. The value can be `on` or `off`.

warning

Expressed as a percentage of the volume capacity for thin-provisioned or compressed volume copies, indicates that a warning is generated when the ratio of `used_capacity` to volume capacity reaches the specified level.

Remember: This field is blank for storage pools that are not thin-provisioned or compressed volume copies in a data reduction pool.

grainsize

For thin-provisioned volume copies, indicates the grain size that is chosen for the volume copy when it was created.

Remember: This value is always blank for compressed volume copies in regular storage pools.

se_copy

Specifies whether the copy is thin-provisioned.

easy_tier

Indicates whether Easy Tier is permitted to manage the pool.

Note:

1. If `easy_tier` is `on`, then `easy_tier_status` can take on any value.
2. If `easy_tier` is `off`, then `easy_tier_status` is `measured` or `inactive`.

easy_tier_status

Indicates which Easy Tier functions are active for the volume copy:

- `active` indicates that a pool is being managed by Easy Tier to provide tier management performance-based pool balancing. For example, extents of this volume copy can be moved for performance (automatic data placement).
- `inactive` indicates that no Easy Tier function is active.
- `balanced` indicates that a pool is being managed by Easy Tier to provide performance-based pool balancing (for example, extents can be moved).
- `measured` indicates that statistics are being gathered for this volume copy, but no extents are moved.

Table 137. Easy Tier setting for storage pools and volumes

Storage pool Easy Tier setting	Number of tiers in the storage pool	Volume copy Easy Tier setting	Volume copy Easy Tier status
Off	One	Off	inactive (see note “1” on page 1663)
Off	One	On	inactive (see note “1” on page 1663)
Off	Two	Off	inactive (see note “1” on page 1663)
Off	Two	On	inactive (see note “1” on page 1663)
Measure	One	Off	measured (see note “2” on page 1663)
Measure	One	On	measured (see note “2” on page 1663)
Measure	Two	Off	measured (see note “2” on page 1663)
Measure	Two	On	measured (see note “2” on page 1663)
Auto	One	Off	measured (see note “2” on page 1663)
Auto	One	On	balanced (see note “3” on page 1663)
Auto	Two	Off	measured (see note “2” on page 1663)
Auto	Two	On	active (see note “4” on page 1663)
On	One	Off	measured (see note “2” on page 1663)
On	One	On	balanced (see note “3” on page 1663)
On	Two	Off	measured (see note “2” on page 1663)
On	Two	On	active (see note “4” on page 1663)

Notes:

1. When the volume copy status is inactive, no Easy Tier functions are enabled for that volume copy.
2. When the volume copy status is measured, the Easy Tier function collects usage statistics for the volume but automatic data placement is not active.
3. When the volume copy status is balanced, the Easy Tier function enables performance-based pool balancing for that volume copy.
4. When the volume copy status is active, the Easy Tier function operates in automatic data placement mode for that volume.

If the volume copy is in image or sequential mode or is being migrated, then the volume copy Easy Tier status is measured instead of active.

The default Easy Tier setting for a storage pool is auto, and the default Easy Tier setting for a volume copy is on. If the setting is on, it means that Easy Tier functions except pool performance balancing are disabled for storage pools with a single tier, and that automatic data placement mode is enabled for all striped volume copies in a storage pool with two or more tiers.

tier

Indicates which tier information is being reported:

- tier0_flash
- tier1_flash
- tier_enterprise
- tier_nearline
- tier_scm

tier_capacity

Indicates the total MDisk capacity that is assigned to the volume in the tier.

Note: For thin-provisioned copies, the capacity by tier is the real capacity.

Note: By design, **tier_capacity** reports blank for thin-provisioned and compressed copies in data reduction pools.

compressed_copy

Indicates whether the volume copy is compressed.

uncompressed_used_capacity

For compressed volume copies, indicates the amount of data written to the volume copy before compression. This field is blank for volume copies in a data reduction storage pool.

used_capacity_before_reduction

Indicates the total amount of data written to a thin-provisioned or compressed volume copy in a data reduction storage pool before data reduction occurs. This field is blank for [standard-provisioned](#) volume copies and volume copies not in a data reduction pool.

parent_mdisk_grp_id

Indicates the physical storage pool ID that the volume extents are allocated from. This value is a numeric string (in the range 0 - 127 characters) or blank.

parent_mdisk_grp_name

Indicates the physical storage pool name that the volume extents are allocated from. This value is an alphanumeric string (in the range 1 - 63 characters) or blank.

encrypt

Indicates whether the volume and its copies are encrypted. The values are yes or no.

deduplicated_copy_count

Indicates the number of data deduplicated volume copies.

deduplicated_copy

Indicates whether the volume copy is data deduplicated. The values are:

- yes
- no

An invocation example

```
lsvdiskcopy -delim :
```

The following output is displayed:

```
vdisk_id:vdisk_name:copy_id:status:sync:primary:mdisk_grp_id:mdisk_grp_name:

Related reference

[addvolume](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdiskcopy](#)

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdiskaccess](#)

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyzevdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

[analyzevdiskbysystem](#)

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolume** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

Syntax

Parameters

-nohdr

By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data is displayed, headings are not displayed.

-delim delimiter

By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

vdisk_id / vdisk_name

Specifies the name or ID of a volume.

Description

The **lsvdiskdependentmaps** command displays FlashCopy mappings that have target volumes that are dependent upon data that is held on the specified *vdisk_id* / *vdisk_name*. This data can be used to determine whether a FlashCopy mapping can be prepared. Issue the command for the target volume *vdisk_id* / *vdisk_name* of the FlashCopy mapping to be prepared. If no FlashCopy mappings are returned, the FlashCopy mapping can be prepared. Any FlashCopy mappings that are returned in the list must be stopped or be in the *idle_or_copied* state before the new FlashCopy mapping can be prepared.

A concise invocation example

```
lsvdiskdependentmaps -delim : 0
```

The concise resulting output

```
id:name  
2:fcmap2  
5:fcmap5
```

[addvolume](#)[copy](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdisk](#)[copy](#)

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyper~~s~~wap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdisk](#)[access](#)

Use the **addvdisk** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyze](#)[vdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

[analyze](#)[vdisk](#)[by](#)[system](#)

Use the **analyzevdisk** command to schedule all existing volumes in system for [available capacity](#) analysis.

[backup](#)[volume](#)

Use the **backupvolume** command to create a volume snapshot.

[backup](#)[volume](#)[group](#)

Use the **backupvolume** command to create a new snapshot for all of the volumes in a volume group.

[ch](#)[vdisk](#)

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

[ch](#)[volume](#)[group](#)

Use the **chvolume** command to change volume group properties.

[expand](#)[vdisk](#)[size](#)

Use the **expandvdisk** command to expand the provisioned capacity of a volume by a specified amount.

[expand](#)[volume](#)

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

[ls](#)[dependent](#)[vdisk](#)[s](#)

Use the **lsdependentvdisk** command to view which volumes go offline if you remove a specific piece of hardware from the system.

[ls](#)[host](#)[vdisk](#)[map](#)

Use the **lshostvdisk** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

[ls](#)[meta](#)[data](#)[vdisk](#)

Use the **lsmetadatavdisk** command to display the information for metadata volume.

[ls](#)[repair](#)[se](#)[vdisk](#)[copy](#)[progress](#)

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairdiskcopyprogress

Use the **lsrepairdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappointies

Use the **lsvdiskfcmappointies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

Syntax

Parameters

-copy *copy_id*

(Optional) Displays a list of MDisk extents that are members of the specified volume copy.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data exists to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

vdisk_name / vdisk_id

(Required) Specifies one or more volume IDs or names.

Description

Note: You cannot specify this command for a thin-provisioned or compressed volume or a volume copy that is in a data reduction storage pool.

The **lsvdiskextent** command displays a list of MDisk IDs and the number of extents that each MDisk provides to the specified volumes.

Each volume is constructed from one or more MDisks. To determine the relationship between a volume and its MDisks, issue the following command:

```
lsvdiskmember vdisk_name / vdisk_id
```

where *vdisk_name / vdisk_id* is the name or ID of the volume. This command displays a list of MDisk IDs that make up the volume.

To determine the number of extents that are provided by each MDisk, issue the following command:

```
lsvdiskextent vdisk_name / vdisk_id
```

where *vdisk_name / vdisk_id* is the name or ID of the volume. This command displays a table of MDisk IDs and the corresponding number of extents that each MDisk provides as storage for the specified volume.

To determine the relationship between MDisks and volumes, issue the following command for each MDisk:

```
lsmdiskmember mdisk_name / mdisk_id
```

where *mdisk_name / mdisk_id* is the name or ID of the MDisk. This command displays a list of IDs that corresponds to the volumes that are using this MDisk.

To determine the relationship between MDisks and volumes, and the number of extents that are used by each volume, you must use the command-line interface. For each MDisk, issue the following command:

```
lsmdiskextent mdisk_name / mdisk_id
```

where *mdisk_name / mdisk_id* is the name or ID of the MDisk. This command displays a table of volume IDs and the corresponding number of extents that are used by each volume.

Note: If the MDisk specified is in a data reduction pool, the output includes all thin-provisioned and compressed volumes in the pool without displaying the number of extents in each.

An invocation example

```
lsvdiskextent -delim : vdisk0
```

The resulting output

```
id:number_extents
0:0
```

Related reference

[addvolume copy](#)

Use the **addvolumecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolumecopy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskfcmapcopies

Use the **lsvdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

Syntax

➤ **lsvdiskfcmappcopies** 

Parameters

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

vdisk_name / vdisk_id

(Required) Specifies the name or ID of the volume for which the FlashCopy mappings are displayed.

Description

This command returns a list of the FlashCopy mappings that have a target volume with a valid copy of the specified volume. The target volumes of these mappings can be considered as candidate source volumes for mappings to restore from.

The mappings that are returned are in the copying, idle_copied, or stopping state with 100% progress.

Note: Maps that are rc_controlled are not shown in the view when this command is specified.

An invocation example

```
lsvdiskfcmapcopies -delim : 0
```

The resulting output

```
id:name:status:progress:difference:start_time:target_vdisk_id:
target_vdisk_name:group_id:group_name
2:fcmap2:copying:80:10:060627083137:10:vdisk10::
5:fcmap5:idle_copied:100:20:060627073130:12:vdisk12:1:fccstgrp1
```

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

Syntax

➤ **lsvdiskfcmappings** 

Parameters

-nohdr

By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data is displayed, headings are not displayed.

-delim delimiter

By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

vdisk_name | vdisk_id

Specifies the name or ID of the volume with FlashCopy mappings that are listed.

Description

The **lsvdiskfcmappings** command returns a list of all FlashCopy mappings that the volume is a member of. The list is returned in no particular order.

An invocation example

```
lsvdiskfcmappings -delim : vdisk2
```

The resulting output

```
fc_id:fc_name
1:fcmap1
3:fcmap3
```

Related reference

addvolume**copy**

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdisk**copy**

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdisk**access**

Use the **addvdisk** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyze**vdisk**

Use the **analyze** command to queue or cancel volume analysis.

analyze**vdisk****by****system**

Use the **analyze** command to schedule all existing volumes in system for [available capacity](#) analysis.

backup**volume**

Use the **backup** command to create a volume snapshot.

backup**volume****group**

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmmapcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumegroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

Syntax

➔ **lsvdiskhostmap** 

Parameters

-nohdr

By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data exists to be displayed, headings are not displayed.

-delim delimiter

By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

vdisk_id / vdisk_name

Specifies the ID or name of the volume. The clustered system displays a list of all the hosts to which this volume is mapped and the Small Computer System Interface (SCSI) ID by which the volume is mapped.

Description

This command displays a list of host IDs and names. These hosts specify a volume that is mapped to them; that is, the volume is visible to these hosts. The SCSI LUN ID is also displayed. The SCSI LUN ID is the ID by which the volume is recognized by the host.

Determining the hosts to which a volume is mapped:

To list the hosts that this volume is mapped to, issue the following command:

```
lsvdiskhostmap vdisk_id | vdisk_name
```

Where *vdisk_id / vdisk_name* is the name or ID of the volume. A list is displayed. Look for the host name or ID to determine which host this volume is mapped to. If no data is displayed, the volume is not mapped to any hosts.

The command returns the following values:

id

Specifies the ID of the volume in the output for **lsvdiskhostmap**.

name

Specifies the name of the volume in the output for **lsvdiskhostmap**.

SCSI_id

Specifies the SCSI ID. This field is blank for NVMe mappings.

host_id

Specifies the ID of the host.

host_name

Specifies the name of the host.

vdisk_UID

Specifies the UID of the volume or the NVMe namespace GUID.

IO_group_id

Specifies the ID of the input/output (I/O) group in which the host volume mapping exists.

IO_group_name

Specifies the name of I/O group in which the host volume mapping exists.

mapping_type

Indicates the mapping type for a host system. Values are **private** or **shared**.

host_cluster_id

Indicates the unique ID for a host system.

host_cluster_name

Indicates the unique name for a host system.

protocol

Indicates the protocol that is used by the hosts that are mapping this volume. The values are **scsi** or **nvme**.

An invocation example

```
lsvdiskhostmap vdisk3
```

The resulting output

id	name	SCSI_id	host_id	host_name	vdisk_UID	IO_group_id	IO_group_name	mapping_type	host_cluster_id	host_cluster_name	protocol
3	vdisk3	3	0	server8	6005076400B10001A000000000000003	0	io_grp0	shared	0	dbcluster	scsi
3	vdisk3	3	1	server9	6005076400B10001A000000000000003	0	io_grp0	shared	0	dbcluster	scsi

Related reference[addvolume](#)**copy**

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdisk](#)**access**

Use the **addvdisk** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyzevdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

[analyzevdisk](#)**by**system

Use the **analyzevdisk** command to schedule all existing volumes in system for [available capacity](#) analysis.

[backupvolume](#)

Use the **backupvolume** command to create a volume snapshot.

[backupvolume](#)**group**

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumeegroup

Use the **lsvolumeegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumeegroup

Use the **mkvolumeegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

Syntax

Parameters

-mdisklba mdisklba

(Required) Specifies the 64-bit hexadecimal LBA on the MDisk. The LBA must be specified in hex, with a 0x prefix.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data exists to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-mdisk mdisk_id / mdisk_name

(Required) Specifies the MDisk name or ID.

Description

The **lsvdisklba** command returns the LBA of the volume that is associated with the MDisk LBA.

If applicable, the command also lists the range of LBAs on both the volume and MDisk that are mapped in the same extent, or for thin-provisioned disks, in the same grain.

Note: If **lsvdisklba** is run during a software upgrade, the command fails and an error message is displayed.

The **vdisk_lba** field provides the corresponding LBA on the virtual capacity for the input LBA. For compressed volume copies, it is blank and the system provides the ranges of virtual LBAs that are compressed into the input LBA.

This table provides command output that depends on several variables.

Table 138. **lsvdisklba** command output scenarios

Field	Typical scenario	Quorum disk	Thin-provisioned metadata	Extent not allocated	Formatting extent	Extent allocated to thin-provisioned disk, LBA not used on thin-provisioned disk
copy_id	yes	no	yes	no	yes	yes
vdisk_id	yes	no	yes	no	yes	yes
vdisk_name	yes	no	yes	no	yes	yes
type	allocated	metadata	metadata	unallocated	formatting	unallocated
vdisk_lba	yes	no	no	no	no	no
vdisk_start	yes	no	no	no	no	no
vdisk_end	yes	no	no	no	no	no
mdisk_start	yes	yes	yes	yes	yes	yes
mdisk_end	yes	yes	yes	yes	yes	yes

An invocation example

```
lsvdisklba -mdisk 1 -mdisklba 0x100123
```

The resulting output:

```
vdisk_id vdisk_name copy_id type      vdisk_lba  vdisk_start vdisk_end  mdisk_start  mdisk_end
0         vdisk0      0         allocated 0x00000123 0x00000000 0x000FFFFF 0x000000000100000 0x0000000001FFFFFF
```

lsdisk

Use the **lsdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsdiskaccess

Use the **lsdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysis

Use the **lsdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsdiskanalysisprogress

Use the **lsdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsdiskcopy

Use the **lsdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsdiskextent

Use the **lsdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsdiskfcmapcopies

Use the **lsdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumebackupgroup

Use the **mkvolumebackupgroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

Syntax

Parameters

-copy *copy_id*

(Optional) Displays a list of MDisks that are members of the specified volume copy.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data exists to be displayed, headings are not displayed.

-delim *delimiter*

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

vdisk_id* / *vdisk_name

(Required) Identifies the specific volume to query.

Description

This command displays a list of managed disks, which provide extents that make up the volume that is specified by the ID.

Every volume is constructed from one or more MDisks. At times, you might have to determine the relationship between the two objects. The following procedure determines the relationships.

If you use the **lsmdiskmember** command, the concise view displays a list of volumes. These volumes are the ones that are using extents on the managed disk that is specified by the ID. The list displays the members of the respective object and is independent of the state of the individual members. If they are in an offline state, they are still displayed.

To determine the relationship between volumes and MDisks, issue the following command:

```
lsvdiskmember vdisk_id | vdisk_name
```

Where *vdisk_id* / *vdisk_name* is the name or ID of the volume. It displays a list of IDs that correspond to the MDisks that make up the volume.

To determine the relationship between volumes and MDisks, and the number of extents that are provided by each MDisk, you must use the command-line interface. Issue the following command:

```
lsvdiskextent vdisk_id / vdisk_name
```

Where *vdisk_id* / *vdisk_name* is the name or ID of the volume. It displays a table of MDisk IDs and the corresponding number of extents that each MDisk provides as storage for the specified volume.

To determine the relationship between MDisks and volumes, issue the following command:

```
lsmdiskmember mdisk_id / mdisk_name
```

Where *mdisk_id* / *mdisk_name* is the name or ID of the MDisk. It displays a list of IDs that correspond to the volumes that are using this MDisk.

To determine the relationship between MDisks and volumes, and the number of extents that are used by each volume, you must use the command-line interface. For a specified MDisk, issue the following command:

```
lsmdiskextent mdisk_id / mdisk_name
```

Where *mdisk_id* / *mdisk_name* is the name or ID of the MDisk. It displays a table of volume IDs and the corresponding number of extents that are used by each volume.

Note: You cannot specify this command for a thin-provisioned or compressed volume or a volume copy that is in a data reduction storage pool.

An invocation example

```
lsvdiskmember 1
```

The resulting output:

```
id
2
```

Related reference

[addvolumecopy](#)

Use the **addvolumecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdiskcopy](#)

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolumecopy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdiskaccess](#)

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyzevdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

[analyzevdiskbysystem](#)

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

[backupvolume](#)

Use the **backupvolume** command to create a volume snapshot.

[backupvolumegroup](#)

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

[chvdisk](#)

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolume group

Use the **chvolume group** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsdiskaccess

Use the **lsdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysis

Use the **lsdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsdiskanalysisprogress

Use the **lsdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsdiskcopy

Use the **lsdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsdiskextent

Use the **lsdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsdiskfcmappcopies

Use the **lsdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumebackupgroup

Use the **mkvolumebackupgroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

Syntax

Parameters

-nohdr

By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If no data is displayed, headings are not displayed.

-delim delimiter

By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by a colon character.

vdisk_id / vdisk_name

Specifies the volume ID or name. If you do not specify this parameter, the progress of all volumes currently being formatted is displayed.

Description

This command displays the progress of the format of a new volume as a completed percentage. If the volume has multiple copies, the command reports the average progress of the format.

The command returns values for the following volume attributes:

id

Indicates the ID of the volume that is being formatted.

progress

Indicates the formatting progress.

estimated_completion_time

Indicates the estimated time in which the formatting operation completes. The value is in the YYMMDDHHMMSS format, and is blank if the duration is not known.

An invocation example

```
lsvdiskprogress -delim : 0
```

The resulting output

```
id:0
progress:58
estimated_completion_time:150101010100
```

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

Syntax

Parameters

-copy *id*

(Optional) Specifies the volume copy ID to list synchronization progress. You must also specify a *vdisk_name* / *vdisk_id* value. If you do not specify this parameter, progress is displayed for all copies.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim *delimiter*

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The -

delim parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

vdisk_name / vdisk_id

(Optional) Specifies the volume name or ID to list synchronization progress.

Description

To display the volume copies that require synchronization, specify the command with no parameters. To display the synchronization progress for all copies of a volume, specify the command with the *vdisk_name / vdisk_id* parameter. Estimated completion time is displayed in the YYMMDDHHMMSS format. The command displays progress for the following special cases as:

- A synchronized copy displays a progress of 100 and a blank estimated completion time.
- An offline copy or a copy with a zero synchronization rate displays a blank estimated completion time. An offline copy displays (gradually) decreasing progress if the volume is being written to.
- Nonmirrored volumes are displayed as a single copy with a progress of 100, and a blank estimated completion time.

The **lsvdisksyncprogress** command also displays the progress of a mirrored volume synchronization. After you create a mirrored volume by using the **mkvdisk** or **addvdiskcopy** command, you can use the command to monitor the progress of the synchronization.

An invocation example

```
lsvdisksyncprogress
```

The resulting output

vdisk_id	vdisk_name	copy_id	progress	estimated_completion_time
0	vdisk0	1	50	070301150000
3	vdisk3	0	72	070301132225
4	vdisk4	0	22	070301160000
8	vdisk8	1	33	

An invocation example

```
lsvdisksyncprogress vdisk0
```

The resulting output

vdisk_id	vdisk_name	copy_id	progress	estimated_completion_time
0	vdisk0	0	100	
0	vdisk0	1	50	070301150000

[addvolume](#)[copy](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdisk](#)[copy](#)

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdisk](#)[access](#)

Use the **addvdisk** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyze](#)[vdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisk

Use the **lsdependentvdisk** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsdiskaccess

Use the **lsdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysis

Use the **lsdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsdiskanalysisprogress

Use the **lsdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsdiskcopy

Use the **lsdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappointies

Use the **lsvdiskfcmappointies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolume group

Use the **mkvolume group** command to create and configure a new volume group.

mkimage volume

Use the **mkimage volume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume copy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (""):
lsvolumebackup -filtervalue volume_id="1*"

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue?

(Optional) Displays a list of valid filter attributes. The following filters for the **lsvolumebackup** command are valid:

- volume_UID
- volume_id
- volume_name
- volume_group_id
- volume_group_name
- cloud_account_id
- cloud_account_name

Description

This command lists the volumes that use cloud snapshot and also lists volumes that have cloud snapshots in the cloud account.

This view spans all cloud accounts. To refresh the view by reloading what is on the cloud, specify `chcloudaccountawss3 -refresh 0` or `chcloudaccountswift -refresh 0`.

A snapshot that is being copied to the cloud (which means the snapshot status value is `copying` or `copying_error`) does not count towards the generation count total for the volume. Not counting towards the generation means that it is not available for a restore, and if there is a local system failure, the generation no longer exists in the cloud.

The specified volume appears in the displayed output when the volume has cloud snapshot that is enabled. The generation count is initially 0 and remains 0 while the volume copy is in progress. The generation count changes to 1 after the copy completes.

The last snapshot time is blank while the first snapshot is in progress. A snapshot that is being deleted from the cloud counts toward the generation count for the volume even if it is not available for a restore.

This table provides the attribute values that can be displayed as output view data.

<i>Table 139. lsvolumebackup output</i>	
Attribute	Description
volume_UID	Indicates the volume UID.
volume_id	Indicates the volume ID if a volume with the specified UID exists on the local system. The value must be a number (or blank).
volume_name	Indicates the volume name. The value must be an alphanumeric string.
volume_group_id	Indicates the volume group ID that the volume is a member of (if applicable), if a volume with the specified UID exists on the local system. The value must be a number (or blank).
volume_group_name	Indicates the volume group name that the volume is a member of (if applicable), if a volume with the specified UID exists on the local system. The value must be an alphanumeric string (or blank).
cloud_account_id	Indicates the ID for the cloud account that contains the volume snapshots.
cloud_account_name	Indicates the cloud account name for the cloud account that contains the volume snapshot. The value must be an alphanumeric string.
last_backup_time	Indicates the timestamp of the most recent snapshot for this volume. The value must be in YYYYMMDDHHMMSS format or blank.

Table 139. *lsvolumebackup* output (continued)

Attribute	Description
generation_count	<p>Indicates the number of snapshot generations that exist for the specified volume. The value must be a number.</p> <p>Note:</p> <ul style="list-style-type: none"> Any generations that are being copied to the cloud do not count towards this number. Any generations that are being deleted count towards this number until the delete process completes.
backup_size	Indicates the approximate amount of storage (the capacity) that is in use by snapshot generations for the specified volume

An invocation example

```
lsvolumebackup
```

The resulting output:

```

volume_UID      volume_id volume_name volume_group_id volume_group_name
cloud_account_id cloud_account_name last_backup_time generation_count backup_size

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumeegroup

Use the **mkvolumeegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

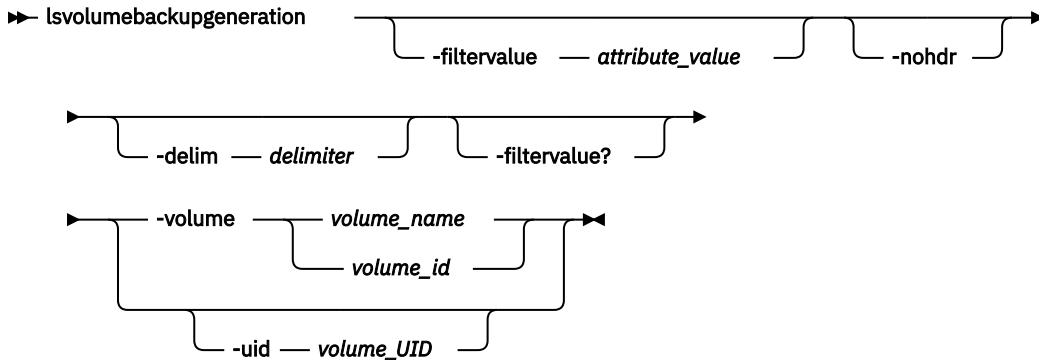

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks ("").

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue?

(Optional) Displays a list of valid filter attributes. The following filters for the **lsvolumebackupgeneration** command are valid:

- state

-volume volume_name / volume_id

(Required) Specifies the volume to list cloud snapshots for by volume ID or name.

Note: The volume must exist on the local system.

The value for volume ID must be a number and the value for volume name must be an alphanumeric string. This parameter is mutually exclusive with **-uid**.

-uid volume_UID

(Optional) Specifies the volume to list cloud snapshots for by volume UID. This parameter is mutually exclusive with **-volume**.

Description

This command lists any available volume snapshots for the specified volume.

This table provides the attribute values that can be displayed as output view data.

Table 140. <i>lsvolumebackupgeneration</i> output	
Attribute	Description
generation_id	Indicates the snapshot generation volume ID. The value must be a number.
backup_time	Indicates the timestamp of the most recent snapshot. The value must be in YYMMDDHHMMSS format (or blank).
volume_group_name	Indicate the volume group name. The value must be an alphanumeric string (or blank).
volume_size	Indicates the provisioned capacity of the volume during snapshot generation. This value can differ from the current volume size (the capacity in MB or GB) if a volume with the specified UID exists on the local system.
type	Indicates the type of volume snapshot generation. The values are <code>full</code> and <code>incremental</code> .
state	Indicates the state of the volume backup generation (in the cloud system). The values are: <ul style="list-style-type: none">• <code>copying</code>• <code>complete</code>• <code>deleting</code>
cloud_upload_size	Indicates the amount of data (the capacity in MB or GB) that is uploaded from the snapshot generation volume to the cloud system.

Generations that are being copied to the cloud account are included in the `copying` state value.

Generations that are being deleted from the cloud account are also included in the `deleting` state value.

An invocation example

```
lsvolumebackupgeneration -volume 2
```

The resulting output:

generation_id	backup_time	volume_group_name	volume_size	type	state	cloud_upload_size
1	160217021250		50.00GB	full	complete	2.83GB
2	160217021355		50.00GB	incremental	complete	177.50MB
3	160218021402		50.00GB	incremental	complete	132.02MB
4	160219021400		50.00GB	incremental	copying	12.43MB

An invocation example

```
lsvolumebackupgeneration -uid 600507680CA880AB12000000000000015
```

The resulting output:

generation_id	backup_time	volume_group_name	volume_size	type	state	cloud_upload_size
1	160215021355		10.00GB	full	complete	53.88MB

addvolumecopy

Use the **addvolume****copy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdisk****copy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume****copy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdisk****access** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyze****vdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyze****vdisk****bysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backup****volume** command to create a volume snapshot.

backupvolumegroup

Use the **backup****volume****group** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolume****group** command to change volume group properties.

expandvdisksize

Use the **expand****vdisk****size** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expand****volume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependent****vdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshost****vdisk****map** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmeta****data****vdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepair****sevdisk****copy****progress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappointies

Use the **lsvdiskfcmappointies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolume group

Use the **lsvolume group** command to display information about configured volume groups.

lsvolume restore progress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecgroup

Use the **rmvolumeecgroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (""):
`lsvolumebackupprogress -filtervalue volume_id="1*"`

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue?

(Optional) Displays a list of valid filter attributes. The following filters for the **lsvolumebackupprogress** command are valid:

- volume_UID
- volume_id
- volume_name
- task
- status

Description

This command display information about the progress of snapshot operations.

This table provides the attribute values that can be displayed as output view data.

<i>Table 141. lsvolumebackupprogress output</i>	
Attribute	Description
volume_UID	Indicates the volume UID. The value must be a number 0 - 32 characters long.
volume_id	Indicates the volume ID (if a volume with the specified UID exists on the local system). The value must be a number (or blank).
volume_name	Indicates the volume name (if a volume with the specified UID exists on the local system). The value must be an alphanumeric string (or blank).
task	Indicates the type of task that is in progress. The values are backup and delete.
status	Indicates the task status. The values are: <ul style="list-style-type: none"> • copying • copying_error • deleting • deleting_error
generation_id	Indicates the generation ID for the volume that is created or deleted. The value must be a number.
backup_time	Indicates the snapshot time for the volume that is copied to the cloud system. The value must be in YYYYMMDDHHMMSS format for snapshot tasks or blank for deletion tasks.

Table 141. <i>lsvolumebackupprogress</i> output (continued)	
Attribute	Description
progress	Indicates the task progress as a percentage. The value must be a number 0 - 99.
error_sequence_number	Indicates a particular error number. The value must be a number (or blank).

An invocation example

```
lsvolumebackupprogress
```

The resulting output:

```

volume_UID      volume_id volume_name task    status    generation_id
backup_time progress error_sequence_number
600507680CA880DF1800000000000002 2      vdisk2      backup copying      6
160218191005 88
600507680CA880DF18000000000000015 15      vdisk15      backup copying_error 19
160218190845 12      122
600507680CA880DF18000000000000015 15      vdisk15      delete deleting
8      5
600507680CA880DF18000000000000017      vdisk108      delete deleting
10      17
600507680CA880DF18000000000000018      vdisk109      delete deleting
many      55

```

[addvolume](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdisk](#)

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdiskaccess](#)

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyzevdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

[analyzevdiskbysystem](#)

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

[backupvolume](#)

Use the **backupvolume** command to create a volume snapshot.

[backupvolume](#)

Use the **backupvolume** command to create a new snapshot for all of the volumes in a volume group.

[chvdisk](#)

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

[chvolume](#)

Use the **chvolume** command to change volume group properties.

[expandvdisksize](#)

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadavdisk

Use the **lsmetadavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDiskS that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to display information about configured volume groups.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to display information about restore operation progress.

mkmetadavdisk

Use the **mkmetadavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumebackup

Use the **mkvolumebackup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

[recovervdiskbyiogrp](#)

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

[recovervdiskbysystem](#)

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

[repairsevdiskcopy](#)

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

[repairvdiskcopy](#)

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

[restorevolume](#)

Use the **restorevolume** command to restore a volume from a snapshot generation.

[rmvdisk](#)

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

[rmmetadatavdisk](#)

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

[rmvdiskcopy](#)

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

[rmvdiskaccess](#)

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

[rmvdiskhostmap](#)

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

[rmvolume](#)

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeecopy](#)

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumegroup](#)

Use the **rmvolumegroup** command to remove a volume group from a system.

[rmvolumebackupgeneration](#)

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvolume group

Use the **lsvolume group** command to display information about configured volume groups.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (""):
lsvolume group -filtervalue id="1*"

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-filtervalue?

(Optional) Displays a list of valid filter attributes. The following filters for the **lsvolume group** command are valid:

- id
- name
- volume_count
- backup_status
- last_backup_time

volume group_id / volume group_name

(Optional) Specifies a volume group ID or volume group name. The value must be a number for the ID and an alphanumeric string for the name.

Description

This command displays information about configured volume groups.

This table provides the attribute values that can be displayed as output view data.

Table 142. lsvolumegroup output	
Attribute	Description
id	Indicates the volume group ID. The value must be a number.
name	Indicates the volume group name. The value must be an alphanumeric string.
volume_count	Indicates the number of volume members in a group. The value must be a number.
backup_status	Indicates whether a new (volume) group snapshot can be started. The values are: <ul style="list-style-type: none">• empty• off• not_ready• ready• copying• copying_error If a group snapshot is in progress, the value represents the snapshot operation status.
last_backup_time	Indicates the most recent volume group snapshot time. The value must be in the YYMMDDHHMMSS format (or blank).
owner_id	Indicates the ID of the ownership group.
owner_name	Indicates the name of the ownership group.

A concise invocation example

```
lsvolumegroup
```

The resulting output:

id	owner_id	owner_name	name	volume_count	backup_status	last_backup_time
0	0	tenantA	VG1	5	copying	160308115216
1	0	tenantA	VG2	0	not_ready	150408115216

A detailed invocation example

```
lsvolumegroup 1
```

The resulting output:

```
id 1
name VG2
volume_count 0
backup_status not_ready
last_backup_time
owner_id 0
owner_name tenantA
```

addvolumecopy

Use the **addvolumecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolumecopy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairvdiskcopyprogress

The **lsrepairvdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

Syntax

Parameters

-filtervalue attribute=value

(Optional) Specifies a list of one or more filters. Only objects with a value that matches the filter attribute value are displayed.

Note: Some filters allow the use of a wildcard when you enter the command. The following rules apply to the use of wildcards:

- The wildcard character is the asterisk (*).
- The command can contain a maximum of one wildcard.
- When you use a wildcard, enclose the filter entry within double quotation marks (""):
`lsvolumerestoreprogress -filtervalue volume_id="1*"`

-nohdr

(Optional) By default, headings are displayed for each column of data in a concise style view, and for each item of data in a detailed style view. The **-nohdr** parameter suppresses the display of these headings.

Note: If there is no data to be displayed, headings are not displayed.

-delim delimiter

(Optional) By default in a concise view, all columns of data are space-separated. The width of each column is set to the maximum width of each item of data. In a detailed view, each item of data has its own row, and if the headers are displayed, the data is separated from the header by a space. The **-delim** parameter overrides this behavior. Valid input for the **-delim** parameter is a 1-byte character. If you enter **-delim :** on the command line, the colon character (:) separates all items of data in a concise view; for example, the spacing of columns does not occur. In a detailed view, the data is separated from its header by the specified delimiter.

-filtervalue?

(Optional) Displays a list of valid filter attributes. The following filters for the **lsvolumerestoreprogress** command are valid:

- volume_id
- volume_name
- task
- status

volume_name / volume_id

(Optional) Indicates the volume name or ID for the volume that is restored. The value for volume name must be an alphanumeric string and the value for volume ID must be a number.

Description

This command displays information about restore operation progress.

This table provides the attribute values that can be displayed as output view data.

<i>Table 143. lsvolumerestoreprogress output</i>	
Attribute	Description
volume_id	Indicates the volume ID for the volume that is restored. The value must be a number (or blank).
volume_name	Indicates the volume name for the volume that is restored. The value must be an alphanumeric string (or blank).
task	Indicates the type of task that is in progress. The value is <code>restore</code> .
status	Indicates the task status. The values are: <ul style="list-style-type: none"> • <code>restoring</code> • <code>restoring_error</code>
generation_id	Indicates the generation ID for the volume snapshot generation that is restored. The value must be a number.
backup_time	Indicates the time for the volume snapshot generation that is being restored to the cloud system (or available on the restore volume). The value must be in YYMMDDHHMMSS format for snapshot tasks or blank for deletion tasks.
progress	Indicates the task progress as a percentage. The value must be a number 0 - 100. The status is blank when the status is uncommitted.
error_sequence_number	Indicates a particular error number. The value must be a number (or blank).

Table 143. *lsvolumerestoreprogress* output (continued)

Attribute	Description
volume_backup_id	Indicates the UID of the volume snapshot that is restored. The value must be a number 1 - 32.
restore_volume_id	Indicates the ID of the volume that is the target of the restore operation. This volume is either the production volume (which means that the restore volume ID is the same as the volume ID) or a temporarily restored volume that is automatically provisioned by the restore process. The value must be a number.
restore_volume_name	Indicates the name of the volume that is the target of the restore operation. This volume is either the production volume (which means that the restore volume name is the same as the volume name) or a temporarily restored volume that is automatically provisioned by the restore process. The value must be an alphanumeric string.

A concise invocation example

```
lsvolumerestoreprogress
```

The resulting output:

```
volume_id volume_name task      status      generation_id backup_time  progress
error_sequence_number
2          vdisk2      restore restoring    17          160102104511 88
21         vdisk21     restore restoring_error 4          160102105023
19                                     122
```

A detailed invocation example

```
lsvolumerestoreprogress vdisk2
```

The resulting output:

```
volume_id 2
volume_name vdisk2
task restore
status restoring
generation_id 17
backup_time 160102104511
progress 88
error_sequence_number
volume_backup_UID 600507680CA880DF1800000000000002
restore_volume_id 2
restore_volume_name vdisk2
```

Related reference

[addvolume](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdisk](#)

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdiskaccess](#)

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyzevdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisk

Use the **lsdependentvdisk** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsdiskaccess

Use the **lsdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysis

Use the **lsdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsdiskanalysisprogress

Use the **lsdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsdiskcopy

Use the **lsdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumegroup

Use the **lsvolumegroup** command to display information about configured volume groups.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolume group

Use the **mkvolume group** command to create and configure a new volume group.

mkimage volume

Use the **mkimage volume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume copy

Use the **rmvolume** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolume](#)

Use the **rmvolume** command to remove a volume group from a system.

[rmvolumebackupgeneration](#)

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdiskspace](#)

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

Syntax

```
➔ mkmetadatavdisk  — -mdiskgrp  ┌─────────── mdiskgrp_id ───────────➔  
                               │  
                               └─────────── mdiskgrp_name ───────────➔
```

Parameters

-mdiskgrp *mdiskgrp_id* | *mdiskgrp_name*

(Required) Assigns one or multiple storage pools for use in creating a metadata volume. The value must be a numeric value for *mdiskgrp_id* and an alphanumeric string for *mdiskgrp_name*.

Description

This command creates one metadata volume from a storage pool.

Note: You cannot specify a data reduction pool with this command.

An invocation example

```
mkmetadatavdisk -mdiskgrp pool_a
```

The resulting output:

```
Virtual Disk, id [2], successfully created
```

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume copy

Use the **rmvolume copy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume group

Use the **rmvolume group** command to remove a volume group from a system.

rmvolume backup generation

Use the **rmvolume backup generation** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

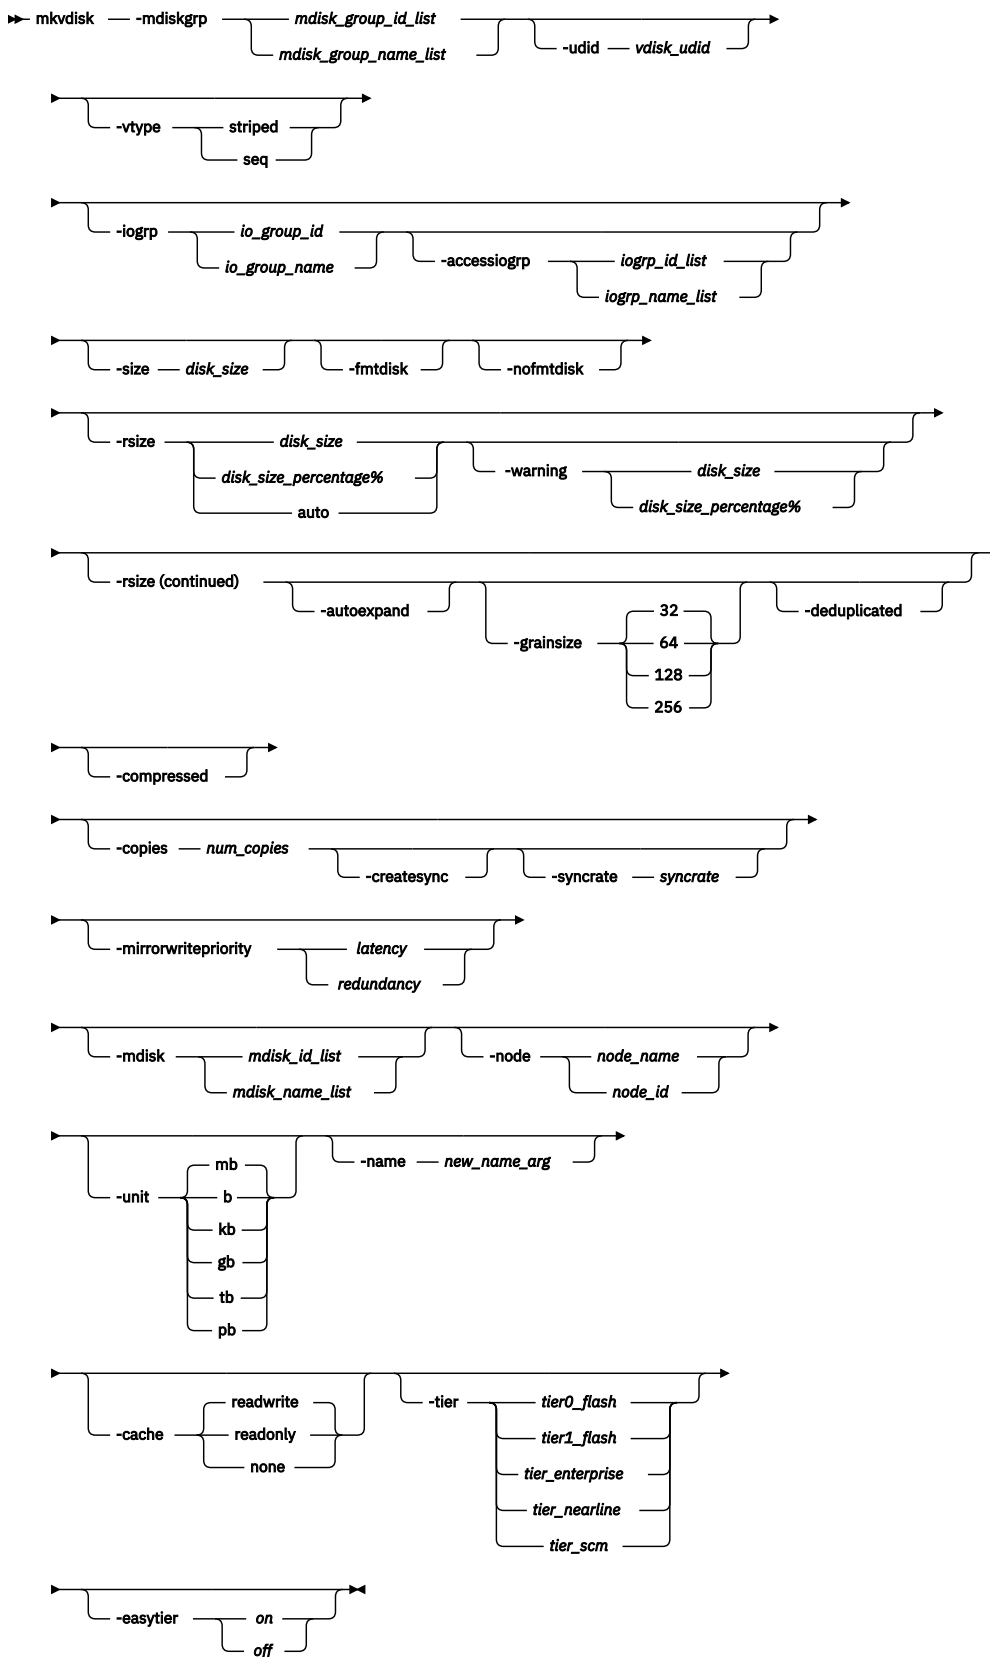

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

Note: The first syntax diagram depicts the creation of a **sequential** or **striped** mode volume. The second syntax diagram depicts the creation of an **image** mode volume.

Syntax

Create a sequential or striped mode volume.

Create an image mode volume.

Parameters

-mdiskgrp *mdisk_group_id_list* | *mdisk_group_name_list*

(Required) Specifies one or more storage pools to use when you are creating this volume. If you are creating multiple copies, you must specify one storage pool per copy. The primary copy is allocated from the first storage pool in the list.

-udid *vdisk_udid*

(Optional) Specifies the unit number *udid* for the disk. The *udid* is an identifier that is required to support OpenVMS hosts; no other systems use this parameter. Valid options are a decimal number 0 - 32 767, or a hexadecimal number 0 - 0x7FFF. A hexadecimal number must be preceded by 0x (for example, 0x1234).

-vtype *seq* | *striped* | *image*

(Optional) Specifies the virtualization type. When you create sequential or image mode volumes, you must also specify the **-mdisk** parameter. You cannot use **-vtype seq** or **-vtype image** in a data reduction pool. The default virtualization type is striped.

-iogrp *io_group_id* | *io_group_name*

(Optional) Specifies the I/O group (node pair) with which to associate this volume. If you specify **-node**, you must also specify **-iogrp**.

Remember:

- Create the first compressed volume copy for an I/O group to activate compression.
- You cannot create or move a volume copy that is compressed to an I/O group that contains at least one node that does not support compressed volumes. You must select another I/O group to move the volume copy to (but it does not affect moving to the recovery I/O group).

-accessiogrp *iogroup_id_list* | *iogroup_name_list*

(Optional) Specifies the members of the volume I/O group access set. If this option is not specified, only the caching I/O group is added to the volume I/O group access set. If this option is specified, then the **-iogrp** option must also be specified and the I/O group access set must include the I/O group that is specified by the **-iogrp** parameter.

-size *disk_size*

(Required for sequential or striped volume creation) (Optional for image volume creation) Specifies the capacity of the volume, which is used with the value of the unit. All capacities, including changes, must be in multiples of 512 bytes. An error occurs if you specify a capacity that is not a multiple of 512. It can only happen when byte units (-b) are used. However, an entire extent is reserved even if it is only partially used. The default capacity is in MB. You can specify a capacity of 0. Specify the size in bytes in multiples of logical block address (LBA) sizes.

Note: If you do not specify the **-size** parameter when you create an image mode disk, the entire MDisk capacity is used.

-fmttdisk

(Optional) Specifies that the volume be formatted. This parameter is no longer required for any volumes.

This parameter is not required when you create [standard-provisioned](#) volumes. The format operation is automatically applied to [standard-provisioned](#) volumes unless you specify **-nofmttdisk** parameter. The format operation sets the extents that make up this volume to all zeros after it is created. This process takes place in the background concurrently with host I/O operations on the new volume.

Remember: Formatting is on by default for single copy, [standard-provisioned](#), and non-image mode volumes. You cannot format an image mode volume.

The format operation completes asynchronously. You can query the status by using the **lsvdiskprogress** command. You cannot specify this parameter with the **-vtype image** parameter.

This parameter is not required when you create thin-provisioned volumes. Thin-provisioned volumes return zeros for extents that are not written to. No format operation is required. This parameter also synchronizes mirrored copies by default.

-nofmtdisk

(Optional) Specifies that formatting be turned off for the new volume.

Remember: Formatting is on by default for single copy, [standard-provisioned](#), and non-image mode volumes, and you can specify this parameter to turn it off.

-rsize disk_size | disk_size_percentage% | auto

(Optional) Defines how much physical space is initially allocated to the thin-provisioned or compressed volume. This parameter makes the volume thin-provisioned; otherwise, the volume is [standard-provisioned](#). Specify the *disk_size | disk_size_percentage* value by using an integer, or an integer immediately followed by the percent character (%). Specify the units for a *disk_size* integer by using the **-unit** parameter; the default is MB. The **-rsize** value can be greater than, equal to, or less than the size of the volume. The **auto** option creates a volume copy that uses the entire size of the MDisk.

If you specify the **-rsize auto** option, you must also specify the **-vtype image** option. If you specify **-import** you must specify **-rsize**.

If the volume is in a data reduction storage pool, the value of the **-rsize** parameter will be ignored in **mkvdisk**. Only its presence or absence is used to determine whether the disk is a data reduction volume copy or a thick volume copy.

-warning disk_size | disk_size_percentage%

(Optional) Requires that the **-rsize** parameter also be specified. Specifies a threshold at which a warning error log is generated for volume copies. A warning is generated when the used disk capacity on the thin-provisioned copy first exceeds the specified threshold.

Note: You cannot specify this parameter for thin-provisioned or compressed volumes that are in data reduction pools.

You can specify a *disk_size* integer, which defaults to MBs unless the **-unit** parameter is specified. Or you can specify a *disk_size%*, which is a percentage of the volume size.

Important: If **-autoexpand** is:

1. Enabled, the default value for **-warning** is 80% of the volume capacity.
2. Not enabled, the default value for **-warning** is 80% of the real capacity.

To disable warnings, specify 0.

-autoexpand

(Optional) Specifies that thin-provisioned copies automatically expand their real capacities by allocating new extents from their storage pool. Requires that the **-rsize** parameter also be specified. If the **-autoexpand** parameter is specified, the **-rsize** parameter specifies a capacity that is reserved by the copy. It protects the copy from going offline when its storage pool runs out of space by having the storage pool to consume this reserved space first.

The parameter has no immediate effect on image mode copies. However, if the image mode copy is later migrated to managed mode, the copy is then automatically expanded.

-grainsize 32 | 64 | 128 | 256

(Optional) Sets the grain size (KB) for a thin-provisioned volume. This parameter also requires that the **-rsize** parameter be specified. If you are using the thin-provisioned volume in a FlashCopy map, use the same grain size as the map grain size for best performance. If you are using the thin-provisioned volume directly with a host system, use a small grain size. The grain size value must be 32, 64, 128, or 256 KB. The default is 256 KB.

If the volume to be created is a thin-provisioned volume in a data reduction storage pool, the **-grainsize** parameter cannot be used. This type of volume will be created with a grain size of 8 KB.

-deduplicated

(Optional) Creates a deduplicated volume. If you specify **-deduplicated**, you must also specify **-rsize** because it applies only to thin-provisioned or compressed volumes.

Note: Data deduplication works only with data reduction storage pools. You can only create deduplicated volumes and volume copies in an I/O group if there are no compressed volumes or volume copies in regular storage pools.

-compressed

(Optional) Enables compression for the volume. This parameter must be specified with **-rsize** and cannot be specified with **-grainsize**.

-import

(Optional) Imports a thin-provisioned volume from the MDisk. If you specify **-import** you must also specify **-rsize**.

-copies num_copies

(Optional) Specifies the number of copies to create. The *num_copies* value can be 1 or 2. Setting the value to 2 creates a mirrored volume. The default value is 1.

-createsync

(Optional) Creates copies in sync. Use this parameter if you have already formatted the MDisk, or when read stability to unwritten areas of the volume is not required.

-syncrate syncrate

(Optional) Specifies the copy synchronization rate. A value of zero (0) prevents synchronization. The default value is 50. See [Table 145 on page 1753](#) for the supported **-syncrate** values and their corresponding rates. Use this parameter to alter the rate at which the [standard-provisioned](#) volume or mirrored volume format before synchronization.

-mirrorwritepriority latency | redundancy

(Optional) Specifies how to configure the mirror write algorithm priority. If not specified, the default value is *latency*.

1. Choosing *latency* means a copy that is slow to respond to a write input/output (I/O) becomes unsynchronized, and the write I/O completes if the other copy successfully writes the data.
2. Choosing *redundancy* means a copy that is slow to respond to a write I/O synchronizes completion of the write I/O with the completion of the slower I/O to maintain synchronization.

-mdisk mdisk_id_list | mdisk_name_list

(Optional) Specifies one or more managed disks. For sequential and image mode volumes, the number of MDisk must match the number of copies. For sequential mode volumes, each MDisk must belong to the specified storage pool. For striped volumes, you cannot specify the **-mdisk** parameter if the **-copies** value is greater than 1.

When you create a single copy striped volume, you can specify a list of MDisk to stripe across.

You must use this parameter to specify an MDisk that has a mode of unmanaged.

-node node_id | node_name

(Optional) Specifies the preferred node ID or the name for I/O operations to this volume. You can use the **-node** parameter to specify the preferred access node. If you specify **-node**, you must also specify **-iogrp**.

Note: This parameter is evaluated by multipath device drivers. The system chooses a default if you do not supply this parameter.

-unit b | kb | mb | gb | tb | pb

(Optional) Specifies the data units to use along with the capacity that is specified by the **-size** and **-rsize** parameters. The default unit type is MB.

-name new_name_arg

(Optional) Specifies a name to assign to the new volume.

-cache readwrite | readonly | none

(Optional) Specifies the caching options for the volume. Valid entries are:

- *readwrite* enables the cache for the volume.
- *readonly* disables write caching while allowing read caching for a volume.
- *none* disables the cache mode for the volume.

The default is *readwrite*.

-tier tier0_flash / tier1_flash / tier_enterprise / tier_nearline / tier_scm
(Optional) Specifies the MDisk tier when an image mode copy is added.

tier0_flash

Specifies a tier0_flash hard disk drive or an external MDisk for the newly discovered or external volume.

tier1_flash

Specifies an tier1_flash (or flash drive) hard disk drive or an external MDisk for the newly discovered or external volume.

tier_enterprise

Specifies a tier_enterprise hard disk drive or an external MDisk for the newly discovered or external volume.

tier_nearline

Specifies a tier_nearline hard disk drive or an external MDisk for the newly discovered or external volume.

tier_scm

Specifies a tier_scm hard disk drive or an external MDisk for the newly discovered or external volume.

ssd

Specifies an SSD (or flash drive) hard disk drive or an external MDisk for the newly discovered or external volume.

nearline

Specifies a nearline hard disk drive or an external MDisk for the newly discovered or external volume.

enterprise

Specifies an enterprise hard disk drive or an external MDisk for the newly discovered or external volume.

Note: This action applies to both copies if you are creating a mirrored volume with two image mode copies by using this command.

-easytier on / off

Determines whether the IBM Easy Tier function is allowed to move extents for this volume.

Note: The **-easytier** parameter must be followed by either *on* or *off*:

- If set to *on*, then Easy Tier functions are active.
- If set to *off*, then Easy Tier functions are inactive.

If the Easy Tier feature is enabled, and if a volume copy is striped and not being migrated, the following table applies.

Table 144. Easy Tier settings for storage pools and volumes			
Storage pool Easy Tier setting	Number of tiers in the storage pool	Volume copy Easy Tier setting	Volume copy Easy Tier status
Off	One	Off	inactive (see note “1” on page 1751)
Off	One	On	inactive (see note “1” on page 1751)
Off	Two	Off	inactive (see note “1” on page 1751)
Off	Two	On	inactive (see note “1” on page 1751)

Table 144. Easy Tier settings for storage pools and volumes (continued)

Storage pool Easy Tier setting	Number of tiers in the storage pool	Volume copy Easy Tier setting	Volume copy Easy Tier status
Measure	One	Off	measured (see note “2” on page 1751)
Measure	One	On	measured (see note “2” on page 1751)
Measure	Two	Off	measured (see note “2” on page 1751)
Measure	Two	On	measured (see note “2” on page 1751)
Auto	One	Off	measured (see note “2” on page 1751)
Auto	One	On	balanced (see note “3” on page 1751)
Auto	Two	Off	measured (see note “2” on page 1751)
Auto	Two	On	active (see note “4” on page 1751)
On	One	Off	measured (see note “2” on page 1751)
On	One	On	balanced (see note “3” on page 1751)
On	Two	Off	measured (see note “2” on page 1751)
On	Two	On	active (see note “4” on page 1751)

Notes:

1. When the volume copy status is inactive, no Easy Tier functions are enabled for that volume copy.
2. When the volume copy status is measured, the Easy Tier function collects usage statistics for the volume but automatic data placement is not active.
3. When the volume copy status is balanced, the Easy Tier function enables performance-based pool balancing for that volume copy.
4. When the volume copy status is active, the Easy Tier function operates in automatic data placement mode for that volume.

If the volume copy is in image or sequential mode or is being migrated, the volume copy Easy Tier status is measured instead of active.

The default Easy Tier setting for a storage pool is auto, and the default Easy Tier setting for a volume copy is on. It means that Easy Tier functions except pool performance balancing are disabled for storage pools with a single tier, and that automatic data placement mode is enabled for all striped volume copies in a storage pool with two or more tiers.

Description

This command creates a new volume object. You can use the command to create various types of volume objects, making it one of the most complex commands.

Remember: You can create a striped volume only in a child pool - you cannot create sequential or image volumes in a child pool.

You must decide which storage pool or storage pools provide the storage for the volume. Use the **lsmdiskgrp** command to list the available storage pools and the amount of free storage in each pool. If you are creating a volume with more than one copy, each storage pool that you specify must have enough space for the size of the volume.

If you create a thin-provisioned or compressed volume from a data reduction storage pool, that volume uses the same properties as the data reduction storage pool. You can create [standard-provisioned](#) volumes from data reduction pools, but these volumes use different data reduction properties.

A thin-provisioned or compressed volume that is in a data reduction storage pool must:

- Not be in sequential or image mode.
- Not have a warning threshold set (using **-warning**).
- Use **-cache readwrite** when caching.
- Have **-autoexpand** enabled.

For thin-provisioned and compressed volume copies that are in data reduction storage pools, the Easy Tier status is taken from the data reduction pool because that data is managed by a central data disk. It means that you cannot specify **-easytier** with thin-provisioned or compressed volumes.

Important: The extent size for the storage pool can limit volume size. Consider the maximum volume size that you want to use when you create storage pools. Refer to the information on creating storage pools for a comparison of the maximum volume capacity for each extent size. The maximum is different for thin-provisioned volumes.

A compressed volume in a data reduction pool can only be created in an I/O group with V5030, V7000, or SVC node types. Thin provisioned volumes can be created on any node type.

No restriction exists for the number of compressed volumes within a data reduction storage pool.

Choose an I/O group for the volume. This action determines which nodes in the system process the I/O requests from the host systems. If you have more than one I/O group, ensure that you distribute the volumes between the I/O groups so that the I/O workload is shared evenly between all nodes. Use the **lsiogrp** command to show the I/O groups and the number of volumes that are assigned to each I/O group.

Note: It is normal for systems with more than one I/O group to have storage pools that have volumes in different I/O groups. FlashCopy processing can make copies of volumes whether the source and target volumes are in the same I/O group. However, if you plan to use intra-system Metro or Global Mirror operations, ensure that both the master and auxiliary volume are in the same I/O group.

The command returns the IDs of the newly created volume.

An encryption key cannot be used when you create an image mode MDisk. To use encryption (when the MDisk has an encryption key), the MDisk must be self-encrypting.

Specify the virtualization type by using the **-vtype** parameter; the supported types are sequential (*seq*), *striped*, and *image*.

sequential (seq)

This virtualization type creates the volume that uses sequential extents from the specified MDisk (or MDisks, if creating multiple copies). The command fails if there are not enough sequential extents on the specified MDisk.

striped

The default virtualization type. If the **-vtype** parameter is not specified, *striped* is the default; all managed disks in the storage pool are used to create the volume. The striping is at an extent level; one extent from each managed disk in the group is used. For example, a storage pool with 10 managed disks uses one extent from each managed disk. It then uses the 11th extent from the first managed disk, and so on.

If the **-mdisk** parameter is also specified, you can supply a list of managed disks to use as the stripe set. It can be two or more managed disks from the same storage pool. The same circular algorithm is used across the striped set. However, a single managed disk can be specified more than once in the list. For example, if you enter **-mdisk 0:1:2:1**, the extents are from the following managed disks: 0, 1, 2, 1, 0, 1, 2, and so forth. All MDisks that are specified in the **-mdisk** parameter must be in the managed mode.

A capacity of 0 is allowed.

image

This virtualization type allows image mode volumes to be created when a managed disk already has data on it, perhaps from a previrtualized subsystem. When an image mode volume is created, it directly corresponds to the (previously unmanaged) managed disk that it was created from. Therefore, except for thin-provisioned image mode volumes, volume logical block address (LBA) x equals managed disk LBA x . You can use this command to bring a nonvirtualized disk under the control of the system. After it is under the control of the system, you can migrate the volume from the single managed disk. When it is migrated, the volume is no longer an image mode volume.

You can add image mode volumes to an already populated storage pool with other types of volumes, such as a striped or sequential.

Important: An image mode volume must be 512 bytes or greater. At least one extent is allocated to an image mode volume.

Remember: If you create a mirrored volume from two image mode MDisks without specifying a **-size** value, the capacity of the resulting volume is the smaller of the two MDisks, and the remaining space on the larger MDisk is not accessible.

Attention:

1. Do not create a volume in an offline I/O group. You must ensure that the I/O group is online before you create a volume to avoid any data loss. This action applies in particular to re-creating volumes that are assigned the same object ID.
2. To create an image mode disk, you must already have a quorum disk present in the system because an image mode disk cannot be used to hold quorum data. Refer to information on quorum disk creation for more details.
3. The command fails if either limit of 2048 volumes per I/O Group or 8192 volume copies per system is reached.

The rate at which the volume copies resynchronize after loss of synchronization can be specified by using the **-syncrate** parameter. This table provides the relationship of the *syncrate* value to the data copied per second.

Note: These settings also affect the initial rate of formatting.

Table 145. Relationship between the syncrate value and the data copied per second	
User-specified syncrate attribute value	Data copied/sec
1 - 10	128 KB
11 - 20	256 KB
21 - 30	512 KB
31 - 40	1 MB
41 - 50	2 MB
51 - 60	4 MB
61 - 70	8 MB
71 - 80	16 MB

Table 145. Relationship between the syncrate value and the data copied per second (continued)	
User-specified syncrate attribute value	Data copied/sec
81 - 90	32 MB
91 - 100	64 MB

An invocation example

```
mkvdisk -mdiskgrp Group0 -size 0
-iogrp 0 -vtype striped -mdisk mdisk1 -node 1
```

The resulting output:

```
Virtual Disk, id [1], successfully created
```

An invocation example for creating an image mode volume

```
mkvdisk -mdiskgrp Group0
-iogrp 0 -vtype image -mdisk mdisk2 -node 1
```

The resulting output:

```
Virtual Disk, id [2], successfully created
```

An invocation example for creating a new volume

```
mkvdisk -mdiskgrp Group0 -size 0 -unit kb
-iogrp 0 -vtype striped -mdisk mdisk1 -node 1 -udid 1234 -easytier off
```

The resulting output:

```
Virtual Disk id [2], successfully created
```

An invocation example for creating a thin-provisioned volume

```
mkvdisk -mdiskgrp Group0 -iogrp 0 -vtype striped -size 10 -unit gb -rsize 20% -autoexpand -grainsize 32
```

The resulting output:

```
Virtual Disk id [1], successfully created
```

An invocation example for creating a compressed volume copy

```
mkvdisk -mdiskgrp 0 -iogrp 0 -size 1 -unit tb -rsize 0 -autoexpand -warning 0 -compressed
```

The resulting output:

```
Virtual Disk id [1], successfully created
```

An invocation example for creating a mirrored image-mode volume

```
mkvdisk -mdiskgrp Group0:Group0 -mdisk mdisk2:mdisk3 -iogrp 0 -vtype image -copies 2
```

The resulting output:

```
Virtual Disk id [1], successfully created
```

An invocation example for creating a mirrored volume

```
mkvdisk -iogrp 0 -mdiskgrp 0:1 -size 500 -copies 2
```

The resulting output:

```
Virtual Disk id [5], successfully created
```

An invocation example for configuring a mirror write algorithm priority

```
mkvdisk -mdiskgrp Group0 -iogrp 0 -vtype striped -mirrorwritepriority redundancy -size 500
```

The resulting output:

```
Virtual Disk id [5], successfully created
```

An invocation example to create a disk with default grain size

```
mkvdisk -iogrp 0 -mdiskgrp 0 -size 100 -rsize 5%
```

The resulting output:

```
Virtual Disk id [5], successfully created
```

An invocation example for creating a volume with I/O groups 0 and 1 in its I/O group access set

```
mkvdisk -iogrp 0 -mdiskgrp 0 -size 500 -accessiogrp 0:1
```

The resulting output:

```
Virtual Disk id [5], successfully created
```

An invocation example for creating a volume with warning considerations

```
mkvdisk -mdiskgrp 6 -size 200 -rsize 50 -iogrp 0
```

The resulting output:

```
Virtual Disk, id [2], successfully created
...
lsvdisk 2
...
warning 20    # threshold in MB = 50 x 80 / 100 = 40 MB; threshold as %age of volume capacity =
40 / 200 * 100 = 20
...
```

An invocation example for creating a volume with warning considerations

```
mkvdisk -mdiskgrp 6 -size 200 -rsize 50 -iogrp 0 -warning 80%
```

The resulting output:

```
Virtual Disk, id [2], successfully created
...
lsvdisk 2
...
warning 80    # displayed as %age of volume capacity
...
```

An invocation example for creating a volume with warning considerations

```
mkvdisk -mdiskgrp 6 -size 200 -rsize 50 -iogrp 0 -autoexpand
```

The resulting output:

```
Virtual Disk, id [2], successfully created
...
lsvdisk 2
...
warning 80    # displayed as %age of volume capacity
...
```

An invocation example to create a volume with the read cache enabled

```
mkvdisk -iogrp 0 -size 10 -unit gb -mdiskgrp 0 -cache readonly
```

The resulting output:

```
Virtual Disk, id [2], successfully created
```

An invocation example to create volume Group0

```
mkvdisk -mdiskgrp Group0 -iogrp io_grp0 -vtype image -mdisk 13 -node 1 -udid 1234 -tier
tier_nearline
```

The resulting output:

```
Virtual Disk, id [0], successfully created
```

An invocation example to turn off formatting while creating volume Burnley1

```
mkvdisk -mdiskgrp Burnley1 -iogrp 0 -mdiskgrp 0:1 -size 500 -nofmtdisk -copies 2
```

The resulting output:

```
Virtual Disk, id [0], successfully created
```

An invocation example to create a deduplicated volume copy

```
mkvdisk -mdiskgrp datareductionpool0 -size 100 -unit gb -iogrp 0 -rsize 0 -autoexpand -
deduplicated
```

The resulting output:

```
Virtual Disk, id [4], successfully created
```

Related reference

[addvolume](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdisk](#)

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdiskaccess](#)

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolume group

Use the **mkvolume group** command to create and configure a new volume group.

mkimage volume

Use the **mkimage volume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume copy

Use the **rmvolume** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolume**group command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolume**backupgeneration command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisk**size command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdisk**copy command to create a separate volume from a synchronized copy of a mirrored volume.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

Syntax

Parameters

-force

(Optional) Allows multiple volume-to-host assignments, which are not normally allowed.

-host host_id / host_name

(Required) Specifies the host to map the volume to, either by ID or by name.

-scsi scsi_num_arg

(Optional) Specifies the Small Computer System Interface (SCSI) logical unit number (LUN) ID to assign to this volume on the given host. The **scsi_num_arg** parameter contains the SCSI LUN ID that is assigned to the volume on the given host for all I/O groups that provide access to the volume. You must check your host system for the next available SCSI LUN ID on the given host bus adapter (HBA). If you do not specify the **-scsi** parameter, the next available SCSI LUN ID in each I/O group that provides access is provided to the host. The **-scsi** parameter is not supported for NVMe hosts. When a volume is mapped to a host that uses the NVMe protocol, the volume namespace ID (NSID) is assigned by the system. **This parameter is mutually exclusive with -allowmismatchedscsiids.**

-allowmismatchedscsiids

(Optional) When you create a new host mapping, this parameter allows the system to allocate non-identical SCSI LUN IDs in the access I/O groups for the volume. This parameter is mutually exclusive with **-scsi**.

vdisk_name / vdisk_id

(Required) Specifies the name of the volume that you want to map to the host, either by ID or by name.

Description

This command creates a new mapping between the volume and the specified host. The volume is presented to the host as if the disk is directly attached to the host. It is only after this command is processed, that the host can perform I/O transactions to the volume.

Optionally, you can assign a SCSI LUN ID to the mapping for SCSI hosts. When the HBA in the host scans for devices that are attached to it, it discovers all volumes that are mapped to its Fibre Channel ports. When the devices are found, each one is allocated an identifier (SCSI LUN ID). For example, the first disk found is usually SCSI LUN 0, and so on. You can control the order in which the HBA discovers volumes by assigning the SCSI LUN ID, as required. If you do not specify a SCSI LUN ID, the cluster automatically assigns the next available SCSI LUN ID, if any mappings already exist with that host. When you issue the **mkvdiskhostmap** command, the assigned SCSI LUN ID number is returned.

For NVMe, the SCSI LUN ID is irrelevant and instead the system assigns the NSID that cannot be changed. When you create a mapping to an NVMe volume, the NSID is returned (The NSID is the `vdisk_ID + 1`).

The **mkvdiskhostmap** command fails if the:

- Host to which this mapping is being made is not associated with any one of the I/O groups in the volume access set
- Volume has more than one I/O group in its access set and the host being mapped to the volume does not support volumes being mapped from multiple I/O groups
- Host protocol is incompatible with the volume protocol
- Volume has more than one access IO group and the host protocol is NVMe
- An identical SCSI LUN ID is not available in all the access I/O groups

If you do not specify a SCSI LUN ID, the system attempts to assign the lowest common SCSI LUN ID in all access I/O groups. The returned ID is the same for all I/O groups to which the volume is mapped.

Use the **-allowmismatchedscsiids** parameter to allow the system to allocate non-identical SCSI LUN IDs in the access I/O groups. The lowest value available in each access I/O group is used. It might not be the same in all access I/O groups. Make sure that the host supports this configuration. This parameter cannot be used with the **-scsi** parameter and is not supported for NVMe hosts. If a volume is mapped to a host that uses the NVMe protocol, the volume namespace ID (NSID) is assigned by the system.

Remember: iSCSI hosts can access volumes that are accessible through multiple I/O groups (as well as single I/O groups).

If you generate different SCSI LUN IDs, only one is returned. The returned ID is for the highest-numbered I/O group to which the volume was mapped. To view other values, issue **lshostvdiskmap** or **lsvdiskhostmap**.

The SCSI LUN ID is used for the highest numbered I/O group to which the volume is mapped.

Some HBA device drivers stop when they find a gap in the SCSI LUN IDs. For example:

- Volume 1 is mapped to Host 1 with SCSI LUN ID 1
- Volume 2 is mapped to Host 1 with SCSI LUN ID 2
- Volume 3 is mapped to Host 1 with SCSI LUN ID 4

When the device driver scans the HBA, it must stop after identifying volumes 1 and 2, because no SCSI LUN is mapped with ID 3. For optimal performance, ensure that the SCSI LUN ID allocation is contiguous.

You can create multiple volume assignments (assigning the same volume to multiple hosts, for example, which might be particularly useful for clustered system hosts assigning a volume to multiple hosts). Normally, multiple volume-to-host assignments are not used because corruption is likely to occur if more than one host can access a disk. However, in certain multiple path environments, a volume must be mapped to more than one host. This includes the IBM SAN File System. To map to more than one host, you must use the **mkvdiskhostmap** command with the **-force** parameter. For example:
`mkvdiskhostmap -host host1 -force 4 mkvdiskhostmap -host host2 -force 4.`

Note: When you assign the same volume to multiple hosts, use the same SCSI ID for all hosts.

These commands create two host-to-volume mappings for volume 4 that map to host1 and host2. Omitting the **-force** parameter causes the mapping to fail if that volume is already mapped to a host.

The command also fails if the host object (to which this mapping is being made) is not associated with the I/O group containing the volume.

If a new mapping is created between a host (type **hide_secondary**) and a volume that is a secondary volume in a remote copy relationship, the:

- Mapping is created for configuration purposes (it can be changed or deleted)
- Secondary volume is not presented to the host

The mapped volume is presented to the host if the:

- Host type is changed to a type other than **hide_secondary**
- Remote copy relationship is stopped by specifying **-access**
- Volume is no longer a secondary volume because the remote copy relationship is deleted or switched

Note: You cannot specify this command if the volume is an auxiliary volume in an active-active relationship or if a volume is a change volume in any type of relationship.

Remember: This command cannot be used on a volume owned by a filesystem.

Note: Due to a limitation in the NVMe specification, HyperSwap volumes and volumes with more than one access I/O group cannot be mapped to NVMe hosts.

An invocation example

```
mkvdiskhostmap -host host1 -scsi 1 5
```

The resulting output:

```
Virtual Disk to Host map, id [1], successfully created
```

Related reference

[addvolume](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdisk](#)

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdiskaccess](#)

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyzevdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

[analyzevdiskbysystem](#)

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

[backupvolume](#)

Use the **backupvolume** command to create a volume snapshot.

[backupvolumegroup](#)

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

[chvdisk](#)

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolume group

Use the **chvolume group** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsdiskaccess

Use the **lsdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysis

Use the **lsdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsdiskanalysisprogress

Use the **lsdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsdiskcopy

Use the **lsdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsdiskextent

Use the **lsdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsdiskfcmapcopies

Use the **lsdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumeegroup

Use the **lsvolumeegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumeegroup

Use the **mkvolumeegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

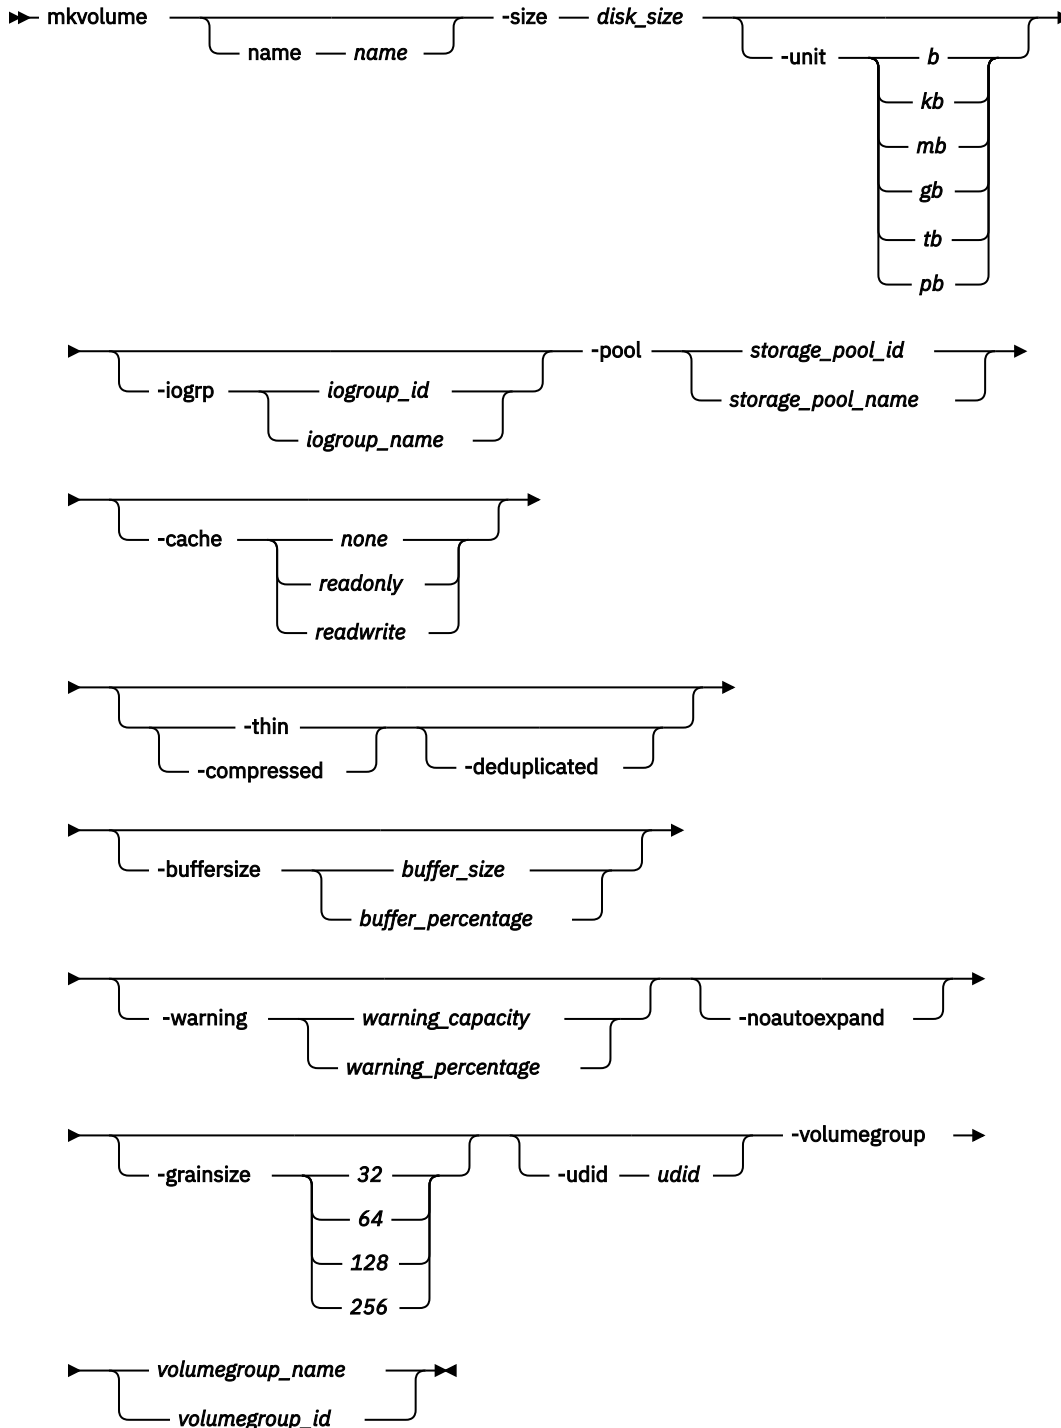

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

Syntax

Parameters

-name *name*

(Optional) Specifies the name that is used for the volume that is created. This value must be an alphanumeric string 1 - 63 characters.

Remember: If you do not specify **-name**, a unique default name such as `volume1` is used.

-size *disk_size*

(Required) Specifies the capacity of the volume, which is used with the value of the unit. The default capacity is in MB. When the unit of bytes is used, all capacities must be in multiples of 512 bytes. An entire extent is reserved even if it is only partially used.

-unit *b | kb | mb | gb | tb | pb*

(Optional) Specifies the data units to use with the capacity that is specified by the **-size** parameter. The default unit type is *mb*.

-iogrp *iogroup_id_list | iogroup_name_list*

(Optional) Specifies the I/O group that the new volume is cached in. The value can be a colon-separated list of up to two I/O group IDs or names. If no value is specified, the caching I/O group is selected based on the storage pool site. If you do not specify the **-iogrp** parameter, the caching I/O group is selected by the system.

Important: If two I/O groups are specified, they must be in different sites, and the storage pools that are specified must be in different sites. The order of the sites must correspond.

If you create a HyperSwap volume, the caching I/O groups are selected based on the sites of the storage pools.

-pool *storage_pool_id_list | storage_pool_name_list*

(Required) Specifies the storage pool in which to create the new volume. The value must be a colon-separated list of up to two storage pool IDs or names.

Note: If one storage pool is specified, a basic volume is created with one copy.

On systems with standard topology, a mirrored volume can be created by specifying two storage pools.

On systems with a stretched or hyperswap topology, a highly available volume can be created by specifying two storage pools in different sites.

-cache *none | readonly | readwrite*

(Optional) Specifies the caching options for the volume. Use one of the following valid entries:

- `readwrite` enables the cache for the volume (default).
- `readonly` disables write caching but allows read caching for a volume.
- `none` disables the cache mode for the volume.

-thin

(Optional) Specifies that the volume is to be created with thin provisioning. You cannot specify this parameter with **-compressed**. If you do not specify **-thin** or **-compressed**, the volume that is created is [standard-provisioned](#).

-compressed

(Optional) Specifies that the volume is to be created compressed. If the **-iogrp** parameter is not specified, the least used I/O group is used for compressed copies (considering the subset of I/O groups that support compression).

Remember: This command fails if no I/O groups support compression. If two sites exist, both sites must have at least one I/O group that supports compression.

You cannot specify this parameter with **-thin**. If you do not specify **-thin** or **-compressed**, the volume that is created is [standard-provisioned](#).

-deduplicated

(Optional) Creates a deduplicated volume. If you specify **-deduplicated**, you must also specify **-rsize** because it applies only to thin-provisioned or compressed volumes.

Note: Data deduplication works only with data reduction storage pools. You can only create deduplicated volumes and volume copies in an I/O group if there are no compressed volumes or volume copies in regular storage pools.

-buffersize *buffer_size* | *buffer_percentage*

(Optional) Specifies the pool capacity the volume attempts to reserve as a buffer for thin-provisioned and compressed volumes. You must specify either **-thin** or **-compressed** with this parameter. The default value is 2%.

Note: You cannot specify a buffer size for thin-provisioned or compressed volumes that are in data reduction pools.

-warning *warning_capacity* | *warning_percentage*

(Optional) Specifies a threshold at which a warning error log is generated for volumes. A warning is generated when the used disk capacity on the thin-provisioned volume exceeds the specified threshold. You must specify either **-thin** or **-compressed** with this parameter. The default value is 80%.

-noautoexpand

(Optional) Specifies that the volume not automatically expand as it is written to. The available buffer capacity decreases as the used capacity increases. The volume copy goes offline if the buffer capacity is fully used. The buffer capacity can be increased by specifying `expandvdiskspace -rsize`. You must specify either **-thin** or **-compressed** with this parameter. If you do not specify **-noautoexpand**, the volume automatically expands as it is written to.

-grainsize *32* | *64* | *128* | *256*

(Optional) Sets the grain size (KB) for a thin-provisioned volume. If you are using the thin-provisioned volume in a FlashCopy map, use the same grain size as the map grain size for best performance. If you are using the thin-provisioned volume directly with a host system, use a small grain size. The grain size value must be 32, 64, 128, or 256 KB. The default is 256 KB.

-udid *udid*

(Optional) Specifies the unit number udid for the volume.

Important: The udid is an identifier that is required to support OpenVMS hosts (no other systems use this parameter).

Valid options are a decimal number from 0 through 32767, or a hexadecimal number from 0 through 0x7FFF. A hexadecimal number must be preceded by 0x (for example, 0x1234).

-volume *volume_name* | *volume_id*

(Optional) Specifies the volume group that a volume belongs to. The value must be an alphanumeric string for the volume group name and the value must be a number for the volume group ID.

Description

This command creates an empty volume, which is a formatted (zeroed) volume, by using storage from existing storage pools. You can also create a highly available volume on systems with stretched or hyperswap topology.

Note: HyperSwap volumes cannot be mapped to NVMe hosts.

If you create a thin-provisioned or compressed volume from a data reduction storage pool, the properties of the storage pool are used for the new volume. You can create [standard-provisioned](#) volumes from data reduction storage pools, but those volumes do not use the storage pool properties.

On some node types, you can create a compressed volume copy in a data reduction storage pool for an I/O group. A compressed volume copy in a data reduction pool can only be created in an I/O group with V5030, V7000, or SVC node types. You can create thin-provisioned volume copies on any node type. Volumes can also have [standard-provisioned](#) volume copies in data reduction storage pools.

You cannot specify **-noautoexpand** when you create thin-provisioned or compressed volume copies from a data reduction storage pool.

You cannot create a volume copy that is a thin-provisioned or compressed volume in a data reduction storage pool, and the volume caching mode is none or readonly. You must specify **chvdisk** to change the volume caching mode to readwrite.

You cannot specify **-warning** for a thin-provisioned or compressed volume copy in a data reduction storage pool.

You cannot specify **-grainsize** for thin-provisioned and compressed volume copies in data reduction storage pools. This type of volume copy is created with a size of 8 KB.

Thin-provisioned or compressed volume copies in data reduction pools cannot be created if the data reduction storage pool is offline and requires recovery. If the recovery is still in progress, you must wait until the recovery is complete and the pool is in online state.

The **mkvolume** command is used for HyperSwap systems and as part of the command automatically creates a base volume and corresponding change volumes that synchronize changes between the two sites. If your HyperSwap system supports FlashCore and the base volume is [standard-provisioned](#) in a data reduction pool, then the corresponding change volume is created with compression enabled. If the base volume is in a standard pool, then the change volume is created as a thin-provisioned volume.

Use the **mkimagevolume** command to create a new volume by importing existing data on a managed disk.

Scenario 1

If the I/O group contains:

- At least one 8 GB node.
- At least one thin-provisioned or compressed volume in a data reduction pool.
- A FlashCopy bitmap size for that I/O group set beyond 1.5 GB.

The command fails due to insufficient resources available.

Scenario 2

When a thin-provisioned or compressed volume is created within a data reduction pool, the pool must have enough capacity to create more volumes that track SCSI unmap operations from the host. If this capacity is not available, the command fails.

Scenario 3

Volumes cannot be created in a data reduction pool if offline thin-provisioned or compressed volumes exist in a data reduction pool, either because of thin provisioning (out of space or corruption), or a component underneath thin provisioning is holding a volume in the pool offline.

An invocation example to create a volume in storage pool 0

```
mkvolume -pool 0 -size 1000
```

The detailed resulting output:

```
Volume, id [0], successfully created.
```

An invocation example for creating a thin-provisioned stretched volume on a system with stretched topology

```
mkvolume -pool site1pool:site2pool -size 1 -unit tb -thin
```

The detailed resulting output:

```
Volume, id [1], successfully created.
```

An invocation example to create a HyperSwap volume with a hyperswap topology

```
mkvolume -pool site1pool:site2pool -size 200
```

The detailed resulting output:

```
Volume, id [2], successfully created.
```

An invocation example to create a thin-provisioned volume from a data reduction storage pool

```
mkvolume -pool datareductionpool2 -size 10 -unit gb -thin
```

The detailed resulting output:

```
Volume, id [6], successfully created.
```

An invocation example to create a deduplicated volume copy

```
mkvolume -pool datareductionpool0 -size 100 -unit gb -iogrp 0 -thin -deduplicated
```

The resulting output:

```
Virtual Disk, id [4], successfully created
```

Use the **lsdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsdiskfcmapcopies

Use the **lsdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumeegroup

Use the **lsvolumeegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolumeegroup

Use the **mkvolumeegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

[recovervdiskbycluster](#) (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

[recovervdiskbyiogrp](#)

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

[recovervdiskbysystem](#)

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

[repairsevdiskcopy](#)

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

[repairvdiskcopy](#)

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

[restorevolume](#)

Use the **restorevolume** command to restore a volume from a snapshot generation.

[rmvdisk](#)

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

[rmmetadatavdisk](#)

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

[rmvdiskcopy](#)

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

[rmvdiskaccess](#)

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

[rmvdiskhostmap](#)

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

[rmvolume](#)

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeecopy](#)

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeegroup](#)

Use the **rmvolumeegroup** command to remove a volume group from a system.

[rmvolumebackupgeneration](#)

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

Syntax

```
➔ mkvolumegroup 
```

Parameters

-name *volumegroup_name*

(Optional) Specifies a volume group name. The value must be an alphanumeric value. If you do not specify a volume group name, one is automatically created and assigned to the volume group.

-ownershipgroup *owner_id / owner_name*

(Optional) The name or ID of the ownership group to which the object is being added.

Description

This command creates and configures a new volume group.

An invocation example

```
mkvolumegroup
```

The resulting output:

```
Volume Group, id [0], successfully created
```

An invocation example

```
mkvolumegroup -name Sunday
```

The resulting output:

```
Volume Group, id [1], successfully created
```

Related reference

[addvolume](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdiskcopy](#)

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdiskaccess](#)

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability

volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume copy

Use the **rmvolume copy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume group

Use the **rmvolume group** command to remove a volume group from a system.

rmvolume backup generation

Use the **rmvolume backup generation** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

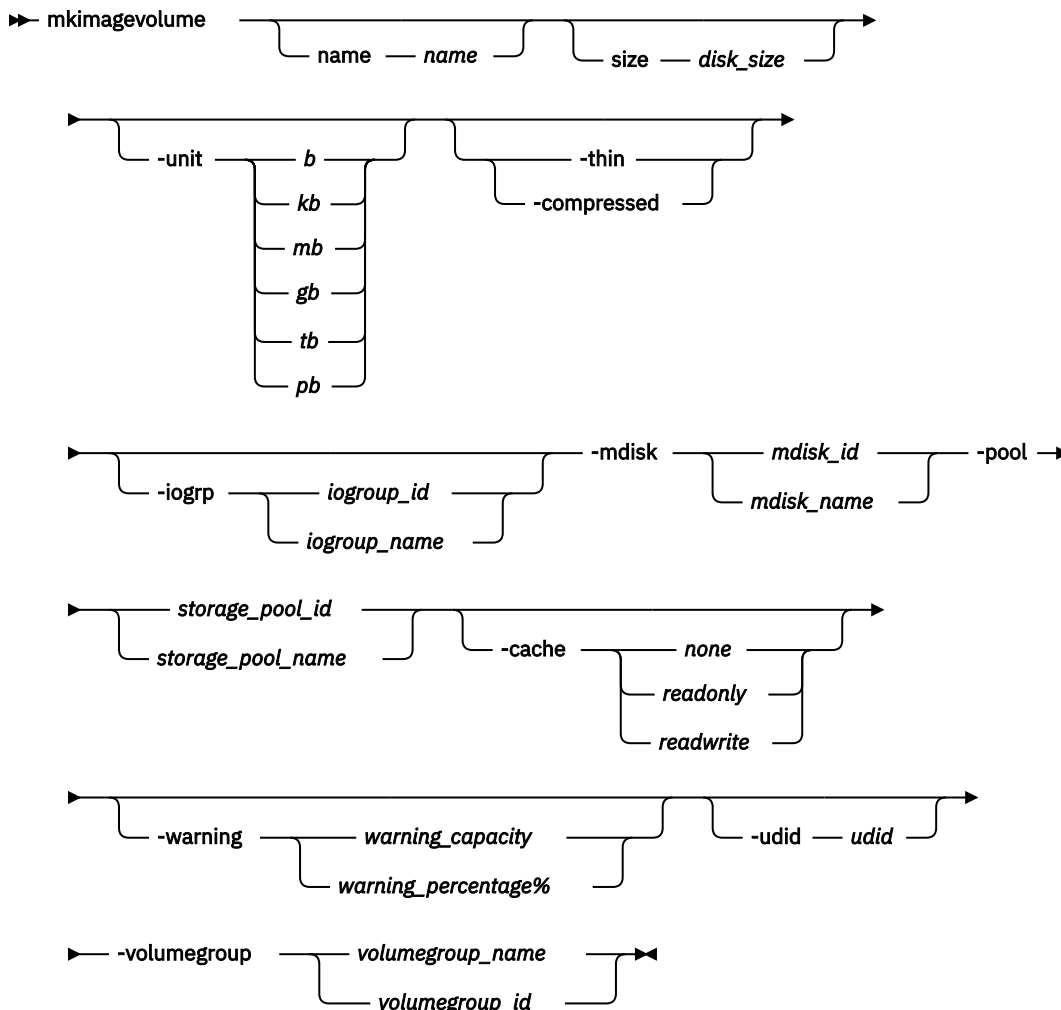

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

Syntax

Parameters

-name *name*

(Optional) Specifies the name that is used for the volume that is created. This value must be an alphanumeric string 1 - 63 characters.

Remember: If you do not specify **-name**, a unique default name such as `volume1` is used.

-size *disk_size*

(Required if **-thin** or **-compressed** is specified) Specifies the capacity of the volume, which is used with the value of the unit. The default capacity is in MB. When the unit of bytes is used, all capacities must be in multiples of 512 bytes. An entire extent is reserved even if it is only partially used.

Remember: This parameter is optional if **-thin** or **-compressed** are not specified. If this parameter is not specified, the volume is [standard-provisioned](#).

For thin and compressed volumes, the real capacity is set from the MDisk size.

-unit *b / kb / mb / gb / tb / pb*

(Optional) Specifies the data units to use with the capacity that is specified by the **-size** parameter. The default unit type is *mb*.

-thin

(Optional) Specifies that the volume is to be created with thin provisioning. You cannot specify this parameter with **-compressed**. If you do not specify **-thin** or **-compressed**, the volume that is created is [standard-provisioned](#).

-compressed

(Optional) Specifies that the volume is to be created compressed. If the `-iogrp` parameter is not specified, the least used I/O group is used for compressed copies (considering the subset of I/O groups that support compression).

Remember: This command fails if no I/O groups support compression.

You cannot specify this parameter with **-thin**. If you do not specify **-thin** or **-compressed**, the volume that is created is [standard-provisioned](#).

-iogrp *iogroup_id / iogroup_name*

(Optional) Specifies the I/O group that the new volume is cached in.

-mdisk *mdisk_id* *mdisk_name*

(Required) Specifies which currently unused MDisk to use to create the image mode volume.

-pool *storage_pool_id / storage_pool_name*

(Required) Specifies the storage pool in which to create the new volume. The value for *storage_pool_id* must be a numerical value.

-cache *none / readonly / readwrite*

(Optional) Specifies the caching options for the volume. Valid entries are:

- `readwrite` enables the cache for the volume (default)
- `readonly` disables write caching but allows read caching for a volume
- `none` disables the cache mode for the volume

-warning *warning_capacity / warning_percentage*

(Optional) Specifies a threshold at which a warning error log is generated for volume copies. A warning is generated when the used disk capacity on the thin-provisioned volume exceeds the specified threshold. You must specify either **-thin** or **-compressed** with this parameter. The default value is 80%.

-udid *udid*

(Optional) Specifies the unit number `udid` for the disk. The `udid` is an identifier that is required to support OpenVMS hosts; no other systems use this parameter. Valid options are a decimal number from 0 through 32767, or a hexadecimal number from 0 through 0x7FFF. A hexadecimal number must be preceded by 0x (for example, 0x1234).

Remember: When you create a HyperSwap volume, this value is set only on the master volume.

-volume group *volume group_name* / *volume group_id*

(Optional) Specifies the volume group that a volume image belongs to. The value must be an alphanumeric string for the volume group name and the value must be a number for the volume group ID.

Description

Use the **mkimagevolume** command to create a new image mode volume. This command is used to import a volume, preserving existing data.

Note: A volume copy in a data reduction pool cannot be an image mode volume copy.

Import a **standard-provisioned** image mode volume into storage pool 0 with MDisk 2 at full capacity

```
mkimagevolume -mdisk 2 -pool 0
```

The detailed resulting output:

```
Volume, id [0], successfully created.
```

Import a **thin-provisioned** image mode volume (with provisioned capacity 25GB) into storage pool 1 with MDisk 7

```
mkimagevolume -mdisk 7 -pool 1 -thin -size 25 -unit gb
```

The detailed resulting output:

```
Volume, id [2], successfully created.
```

addvolume copy

Use the **addvolume copy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdisk copy

Use the **addvdisk copy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyper swap topology, use the **addvolume copy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdisk access

Use the **addvdisk access** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdisk by system

Use the **analyzevdisk by system** command to schedule all existing volumes in system for **available capacity** analysis.

backup volume

Use the **backup volume** command to create a volume snapshot.

backup volume group

Use the **backup volume group** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolume group

Use the **chvolume group** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsdisk

Use the **lsdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsdiskaccess

Use the **lsdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysis

Use the **lsdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsdiskanalysisprogress

Use the **lsdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsdiskcopy

Use the **lsdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsdiskextent

Use the **lsdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsdiskfcmapcopies

Use the **lsdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumeegroup

Use the **lsvolumeegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumeegroup

Use the **mkvolumeegroup** command to create and configure a new volume group.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

Syntax

Parameters

-iogrp iogrp_id | iogrp_name

(Optional) Specifies the I/O group to move the volume to.

-nocachingiogrp

(Optional) If you specify this parameter, the volume has no caching I/O group. This option should be used under the direction of IBM Support only. The **-nocachingiogrp** parameter is mutually exclusive with the **-iogrp** and **-node** parameters.

-force

(Optional) Use the force parameter to force the volume to be removed from an I/O group. This option overrides the cache flush mechanism.

Remember:

- If you specify the **-force** parameter, the contents of the cache are discarded and the volume might be corrupted by the loss of the cached data. Use the **-force** parameter with caution.
- If the force parameter is used to move a volume that has out-of-sync copies, a full resynchronization is required.

-node node_id | node_name

(Optional) Specifies the node ID or name that is assigned as the preferred node.

vdisk_id | vdisk_name

(Required) Specifies the volume to move.

Description

Use the **movevdisk** to migrate a single volume to a new I/O group - repeat this action for other volumes as required. This command can also move the preferred node of a volume without changing the caching I/O group, but it does not change which I/O groups can access the volume (only the caching I/O group is changed).

Important: You cannot migrate or move an image mode volume.

If you are moving volumes in preparation to remove the original I/O group completely, the FlashCopy mappings must be deleted first. Otherwise, the source volumes go offline.

This command is not supported to change the I/O group if either copy is thin-provisioned or compressed and within a data reduction pool. The preferred node can be changed for volumes that are in data reduction pools.

A compressed volume can also be moved, and you can specify the preferred node in the new I/O group. You can move a volume that is in a FlashCopy mapping, but the FlashCopy bitmaps remain in the original I/O group. You cannot move volumes when the FlashCopy mapping is in preparing or prepared state. Additionally, a volume can be moved if it is the target of a FlashCopy mapping that is in stopping state.

You cannot move a volume to change the caching I/O group for a volume that is in a Global Mirror, Metro Mirror, or HyperSwap relationship, regardless of whether it is a primary, secondary, or change volume. To move a volume in a Global Mirror, Metro Mirror, or HyperSwap relationship, the relationship must first be deleted. You can change a preferred node without changing caching I/O group for this type of a volume.

If the volume is offline, use one of the **recovervdisk** commands to recover the volume and bring it back online. To specify a preferred node for the volume, use the **-node node_id | node_name** parameter with the **movevdisk** command. Use the **movevdisk** command to change the I/O group with which this volume is associated.

Important: Do not move:

- A volume to an offline I/O group under any circumstance.

Remember: To avoid data loss, make sure that the I/O group is online before you move the volume.

- An offline volume to the recovery I/O group.

You can migrate a volume to a new I/O group to manually balance the workload across the nodes in the clustered system. You might end up with a pair of nodes that are overworked and another pair of nodes that are underworked.

Remember: You cannot move a volume if that volume is being formatted.

If the volume is a target of a FlashCopy mapping with a source volume in an active-active relationship, then the new I/O group must be in the same site as the source volume. The system permits moving a volume in a remote copy relationship if the move does not change the I/O group (it changes the preferred node). If the volume is in an active-active relationship, the new I/O group must be in the same site as the source I/O group.

Note: Remote copy includes Metro Mirror, Global Mirror, and HyperSwap.

An invocation example to move DB_Volume to I/O group 2

```
movevdisk -iogrp 2 DB_Volume
```

The resulting output:

```
No feedback
```

An invocation example to move DB_Volume to I/O group IOGRP3 with a new preferred node ID 7

```
movevdisk -iogrp IOGRP3 -node 7 DB_Volume
```

The resulting output:

```
No feedback
```

An invocation example to change preferred node of volume DB_Volume with a new preferred node ID as 8 in the same IOGRP

```
movevdisk -node 8 DB_Volume
```

The resulting output:

No feedback

addvolumecopy

Use the **addvolumecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolumecopy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappointies

Use the **lsvdiskfcmappointies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

Syntax

➔ **recovervdisk** 

Parameters

vdisk_name / vdisk_id

(Required) Specifies the volume to recover.

-copy copy_id

(Optional) Specifies the ID of the copy to recover.

Description

The specified volume, and all copies if mirrored, are recovered and brought back online. If the volume is thin-provisioned or has thin-provisioned copies, this command triggers the thin-provisioned repair process. If the volume is mirrored, the **recovervdisk** command triggers a resynchronization from a synchronized copy. The progress of the resynchronization can be monitored by using the **lsvdisksyncprogress** command. The volume remains online during the resynchronization process.

The **recovervdisk** command also starts the repair of any thin-provisioned copies that have a `fast_write_state` of corrupt. The progress of the repair process can be monitored by using the **lsrepairsevdiskcopyprogress** command.

A volume that is still offline because it is being repaired following the **recovervdisk** command has a `fast_write_state` of repairing. The volume is brought online when the repair process is complete.

An invocation example (to recover volume 45)

```
recovervdisk vdisk45
```

The following command is an invocation example to recover copy 0 of volume 45:

```
recovervdisk -copy 0 vdisk45
```

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmapcopies

Use the **lsvdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumegroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

Related reference

addvolumeecopy

Use the **addvolumeecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolume** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolume** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsmetadatavdisk

Use the **lsmetadatavd** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdisk** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdisk** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdisk** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdisk** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmapcopies

Use the **lsvdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations.

Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolume group

Use the **mkvolume group** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

Syntax

➔ **recovervdiskbyiogrp** 

Parameters

io_group_name* / *io_group_id

(Required) Specifies the I/O group for volume recovery.

Description

All volumes in the specified I/O group that have a fast_write_state of corrupt; and all copies, if mirrored, are recovered and brought back online. If any of the volumes are thin-provisioned or have thin-provisioned copies, the **recovervdiskbyiogrp** command triggers the thin-provisioned repair process. If volumes are mirrored, the command triggers a resynchronization from a synchronized copy. The progress of the resynchronization can be monitored by using the **lsrepairsevdiskcopyprogress** command. Volumes remain online during the resynchronization process.

If none of the volumes in the specified I/O group have a fast_write_state of corrupt, the **recovervdiskbyiogrp** command still starts the repair process for any corrupted copies of mirrored volumes. The progress of the repair process can be monitored by using the **lsrepairsevdiskcopyprogress** command. If no corrupted volumes exist or no repairs to copies are needed, no error is returned.

Volumes that are still offline because they are being repaired following the **recovervdiskbyiogrp** command have a fast_write_state of repairing. Volumes are brought online when the repair process is complete.

An invocation example

```
recovervdiskbyiogrp iogrp2
```

The following output is displayed:

```
No feedback
```

Related reference

[addvolume](#)[copy](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdisk](#)[copy](#)

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdisk](#)[access](#)

Use the **addvdisk** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyze](#)[vdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

[analyze](#)[vdisk](#)[bysystem](#)

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

[backup](#)[volume](#)

Use the **backupvolume** command to create a volume snapshot.

[backup](#)[volume](#)[group](#)

Use the **backupvolume** command to create a new snapshot for all of the volumes in a volume group.

[chvdisk](#)

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

[chvolume](#)[group](#)

Use the **chvolume** command to change volume group properties.

[expand](#)[vdisk](#)[size](#)

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

[expand](#)[volume](#)

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

[lsdependent](#)[vdisks](#)

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

[lshost](#)[vdisk](#)[map](#)

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

[lsmeta](#)[data](#)[vdisk](#)

Use the **lsmetadatavdisk** command to display the information for metadata volume.

[lsrepair](#)[sevdisk](#)[copy](#)[progress](#)

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumegroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

Syntax

➤ **recovervdiskbysystem** ➤

Parameters

There are no parameters for this command.

Description

Note: Use this command only under the supervision of IBM Support personnel.

All volumes in the system that have a `fast_write_state` of `corrupt`; and all copies, if mirrored, are recovered and brought back online. If any of the volumes are thin-provisioned or have thin-provisioned copies, the **recovervdiskbysystem** command triggers the thin-provisioned repair process. If volumes are mirrored, the command triggers a resynchronization from a synchronized copy. The progress of the resynchronization can be monitored by using the **lsvdisksyncprogress** command. Volumes remain online during the resynchronization process.

If none of the volumes in the system have a `fast_write_state` of `corrupt`, the **recovervdiskbysystem** command still starts the repair process for any corrupt copies of mirrored volumes. The progress of the repair process can be monitored using the **lsrepairsevdiskcopyprogress** command. If there are no corrupt volumes or no repairs to copies are required, no error is returned.

Volumes that are still offline because they are being repaired following the **recovervdiskbysystem** command have a `fast_write_state` of `repairing`. Volumes are brought online when the repair process is complete.

An invocation example

```
recovervdiskbysystem
```

The resulting output:

```
No feedback
```

addvolumecopy

Use the **addvolume****copy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdisk****copy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume****copy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdisk****access** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolume****group** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolume****group** command to change volume group properties.

expandvdisksize

Use the **expandvdisk****size** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmapcopies

Use the **lsvdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the `lsvdisksyncprogress` command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumegroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

Syntax

➤ **repairsevdiskcopy** 

Parameters

-copy 0 | 1

(Optional) Specifies the volume copy to repair.

vdisk_name* / *vdisk_id

(Required) Specifies the volume to repair.

Description

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume or compressed volume copy. Run this command only when you are directed by the fix procedures or by your product support information.

Running the command automatically detects corrupted metadata. The command holds the volume offline during the repair. During this time there are limited operations permissible.

If a repair operation completes successfully and the volume was previously offline because of corrupted metadata, the command brings the volume back online. The only limit on the number of concurrent repair operations is the number of volume copies in the configuration. Once started, a repair operation cannot be paused or canceled; the repair can only be ended by deleting the copy.

An invocation example

```
repairsevdiskcopy vdisk8
```

The resulting output:

```
No feedback
```

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or `stretched` systems, but it can also be used for volumes that are not high availability.

mkvolumebackupgroup

Use the **mkvolumebackupgroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

[recovervdiskbycluster](#) (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

[recovervdiskbyiogrp](#)

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

[recovervdiskbysystem](#)

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

[repairvdiskcopy](#)

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

[restorevolume](#)

Use the **restorevolume** command to restore a volume from a snapshot generation.

[rmdisk](#)

Use the **rmdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

[rmmetadatavdisk](#)

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

[rmdiskcopy](#)

Use the **rmdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

[rmdiskaccess](#)

Use the **rmdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

[rmdiskhostmap](#)

Use the **rmdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

[rmvolume](#)

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeecopy](#)

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeegroup](#)

Use the **rmvolumeegroup** command to remove a volume group from a system.

[rmvolumebackupgeneration](#)

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

Syntax

Parameters

-medium

(Optional) Converts sectors that contain different readable data into virtual medium errors on the specified volume. It fixes preexisting medium errors found on only one volume copy by replacing them with data from the other volume copy. This parameter cannot be used with the **-validate** and **-resync** parameters. You must specify one of the three parameters.

-resync

(Optional) Corrects sectors that contain different readable data by copying contents from the primary volume copy to other copies on the specified volume. It fixes preexisting medium errors found on only one volume by replacing them with data from the other volume. This parameter cannot be used with the **-medium** and **-validate** parameters. You must specify one of the three parameters.

-validate

(Optional) Reports the first difference in readable data found on synchronized online copies of the specified volume, on or after the specified **-startlba** value. This parameter cannot be used with the **-medium** and **-resync** parameters. You must enter one of the three parameters.

-startlba lba

(Optional) Specifies a starting logical block address (LBA) on which to begin the command. The LBA must be specified in hex, with a 0x prefix.

vdisk_name / vdisk_id

(Required) Specifies the volume to repair. You must specify this parameter last on the command line.

Description

The **repairvdiskcopy** command detects and optionally, corrects any volume copies that are not identical. For the purposes of comparison, preexisting medium errors found on only one volume are ignored and fixed by replacing them with data from the other volume copy. The results are logged to the SAN Volume Controller error log. The **-validate** parameter compares synchronized online copies of the specified volume. The **-medium** parameter changes any sectors that are not identical into virtual medium errors. The **-resync** parameter copies any sectors that are not identical to the other volume copies. You cannot use this command with a volume that is fast formatting.

You must specify **-validate**, **-medium**, or **-resync**.

Attention:

1. Before you run the **repairvdiskcopy** command, ensure that all volume copies are synchronized.
2. Only one **repairvdiskcopy** command can run on a volume at a time. You must wait for the **repairvdiskcopy** command to complete processing before running the command again.
3. Once you start the **repairvdiskcopy** command, you cannot use the command to stop processing.

4. The primary copy of a mirrored volume cannot be changed while the **repairvdiskcopy -resync** command is running.

Use the **-startlba** parameter to specify a starting Logical Block Address (LBA). Enter an LBA value from 0 to full disk size minus one. The parameter logs the first error found and then stops the command. By repeating this parameter, you can collect all of the instances where the volume copies are not identical.

During **repairvdiskcopy** command operation, the volume remains online. The I/O and synchronization operations are allowed while the command is in progress.

The rate for the **repairvdiskcopy** command is controlled by the synchronization rate of the volume that is being repaired. To suspend the repair process, set the synchronization rate of the volume to 0 using the **chvdisk** command.

An invocation example

```
repairvdiskcopy -resync -startlba 0x0 vdisk8
```

The resulting output:

```
No feedback
```

addvolumecopy

Use the **addvolumecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolumecopy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumebackupgroup

Use the **mkvolumebackupgroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

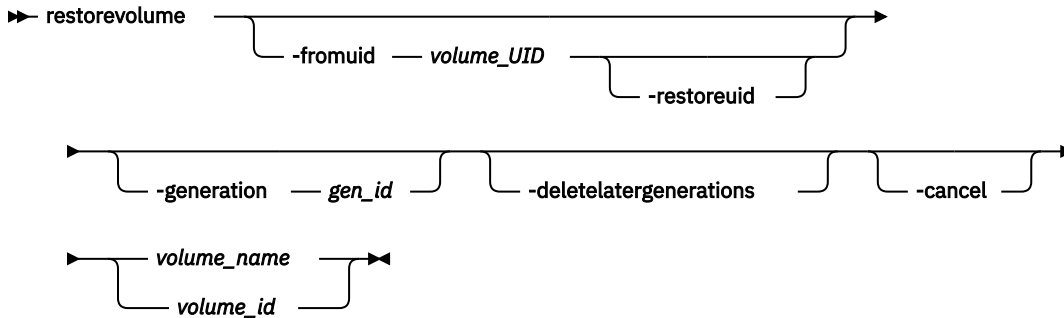

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

Syntax

Parameters

-fromuid *volume_UID*

(Optional) Specifies the volume snapshot to restore (specified by volume UID). The value must be a number.

Use this parameter to restore a snapshot from a different volume. This means that the specified UID must be different from the UID of the volume being restored (when you specify *volume_name* or *volume_id*).

Note: The volume being restored to cannot have cloud snapshot enabled if you specify this parameter.

-restoreuid

(Optional) Specifies the UID of the restored volume should be set to the UID of the volume snapshot that is being restored. You must specify **-fromuid** with this parameter.

-generation *gen_id*

(Optional) Specifies the snapshot generation to restore. The value must be a number.

-deletelatergenerations

(Optional) Specifies that all snapshot generations should be deleted after the generation is restored.

Note: This parameter is required when the volume has cloud snapshot enabled and the generation being restored is not the most recent snapshot of the volume.

-cancel

(Optional) Cancels the restore operation.

volume_name / **volume_id**

(Required) Specifies the volume name or ID to restore. The value for the volume ID must be a number and the value for the volume name must be an alphanumeric string.

Description

This command restores a volume from a snapshot generation.

The restore operation is performed directly on the volume specified by volume name or volume ID (without use of a temporary volume). The volume is **offline** while the restore operation is in progress. If the restore process is canceled before it completes the data on the volume is inconsistent and not usable.

An invocation example

To restore an earlier generation (generation 3) for volume volume7:

```
restorevolume -generation 3 -deletelatergenerations volume7
```

The resulting output:

```
No feedback
```

An invocation example

To restore the most recent snapshot (generation 5) for volume ID 7:

```
restorevolume -generation 5 volume7
```

The resulting output:

```
No feedback
```

An invocation example

```
restorevolume -generation 1 -fromuid 6005076400B70038E00000000000001C 1
```

The resulting output:

```
No feedback
```

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

Syntax

Parameters

-force

(Optional) The specified volume is to be deleted, even if mappings still exist between this volume and one or more hosts. Host-to-volume mappings and any FlashCopy mappings that exist for this volume are deleted.

Important: If you stop a FlashCopy mapping that has dependent FlashCopy mappings, the dependent mapping target volumes might become unusable.

If you stop a FlashCopy mapping whose target volume is also in a Metro Mirror or Global Mirror relationship, the relationship stops. If a remote copy relationship that is associated with the target was mirroring I/O when the map was copying, the relationship might lose its difference recording capability and require a full resynchronization on a subsequent restart.

To determine your dependent FlashCopy mappings before you use the **-force** parameter, run the **lsfcmapdependentmaps** command.

Important: To prevent an active volume from being deleted unintentionally, you can use a global system setting to enable volume protection (see parameters **-vdiskprotectionenabled** and **-vdiskprotectiontime** in the **chsystem** command). You can specify a time period for which the volume must be idle before you can delete it. If volume protection is enabled and the time period is not expired, the volume deletion fails even if the **-force** or **-removehostmappings** parameters are used.

If the **-force** deletion of a volume causes dependent mappings to be stopped, any target volumes for those mappings that are in Metro Mirror or Global Mirror relationships are also stopped. The dependent mappings can be identified by using the **lsvdiskdependentmaps** command on the volume that you want to delete.

Note: Using the **-force** parameter might result in a data loss. Use it only under the direction of your product support information, or if you are willing to accept the risk of volume data loss.

If you do not specify this parameter, a volume cannot be deleted while a backup operation is in progress. Additionally, a volume that contains image mode copies cannot be deleted while a restore operation is in progress (if the volume contains inconsistent data).

-removehostmappings

(Optional) Removes all host mappings for the specified volume before the volume is deleted.

Note: Using the **-removehostmappings** parameter might result in a data loss. Use it only under the direction of your product support information, or if you are willing to accept the risk of volume data loss.

Important: To prevent an active volume from being deleted unintentionally, you can use a global system setting to enable volume protection (see parameters **-vdiskprotectionenabled** and **-vdiskprotectiontime** in the **chsystem** command). You can specify a time period for which the

volume must be idle before you can delete it. If volume protection is enabled and the time period is not expired, the volume deletion fails even if the **-force** or **-removehostmappings** parameters are used.

vdisk_id / vdisk_name

Specifies the name of the volume to delete, either by ID or by name.

Note: To deactivate compression, use the **rmvdiskcopy** to delete the last compressed volume copy for an I/O group.

Description

This command deletes an existing managed mode volume or an existing image mode volume. The extents that made up this volume are returned to the pool of free extents that are available on the storage pool, if the volume is in managed mode.

Remember: If you run this command, any data that was on the volume is lost. Before you run this command, ensure that the volume (and any data that resides on it) is no longer required.

This command is unsuccessful if:

- Volume protection is enabled (by using the **chsystem** command).
- The volume that is being removed received I/O within the defined volume protection time period.
- The data reduction pool is corrupted.

With an active-active relationship, either or both of the master and auxiliary volumes can provide the information for host systems to read through the master volume ID. To remove the auxiliary volume from the relationship, delete the relationship so hosts can access the master copy.

Remember: Any FlashCopy mappings with the specified volume as their source volume are deleted when you specify this command.

Deleting a managed mode volume

When you use this command to delete a managed mode volume, all the data on the volume is deleted. The extents that make up the volume are returned to the pool of free extents that are available in the storage pool.

If host mappings exist for the volume, or if any FlashCopy mappings would be affected, the deletion fails. You can use the **-force** parameter to force the deletion. If you use the **-force** parameter, mappings that have the volume as source or target are deleted, other mappings in a cascade might be stopped, and then the volume is deleted. The **-force** parameter also deletes any Metro Mirror or Global Mirror relationships that exist for the specified volume (and any information that is not staged in the fast write cache).

If the volume is in the process of migrating to an image mode volume (by using the **migratetoimage** command), the deletion fails unless you use the **-force** parameter. If you use the **-force** parameter, the migration is halted and then the volume is deleted. Before you run this command, ensure that the volume (and any data that resides on it) is no longer required.

Deleting an image mode volume

If the volume is mirrored and one or both copies is in image mode, you must first wait for all fast-write data to be moved to the controller logical unit. This pause ensures that the data on the controller is consistent with the data on the image mode volume before the volume is deleted. This process can take several minutes to complete, and is indicated by the `fast_write_state` of the volume, which is empty. If the **-force** parameter is specified, the fast-write data is discarded and the volume is deleted immediately; the data on the controller logical unit is left inconsistent and unusable. If the copies are not synchronized, you must use the **-force** parameter.

If you run the command while data is in the cache, the system attempts to move the data out of the cache; this process can time out, however.

If any virtual medium errors exist on the volume, the command fails. You can force the deletion by using the **-force** parameter; however, using **-force** can cause data integrity problems.

Note: A virtual medium error occurs when you copy data from one disk (the source) to another (the target). Reading the source indicates that a medium error was found. At that moment, you must have two identical copies of data and you must then simulate a medium error on the target disk. You can simulate a medium error on the target disk by creating a virtual medium error on the target disk.

If FlashCopy mappings or host mappings exist for the volume, the deletion fails unless you use the **-force** parameter. If you use the **-force** parameter, mappings are deleted and the volume is deleted. If any data is not staged in the fast write cache for this volume, the deletion of the volume fails. When the **-force** parameter is specified, any data that is not staged in the fast write cache is deleted. Deleting an image mode volume causes the managed disk that is associated with the volume to be removed from the storage pool. The mode of the managed disk is returned to unmanaged.

If the relationship is in `consistent_copying` or `consistent_stopped` state, and the change volume is being used by a Global Mirror relationship that uses multicycling mode, the relationship moves to `inconsistent_copying` or `inconsistent_stopped` state.

Note: If the relationship is part of a consistency group, the entire group is affected by this state transition.

The secondary volume becomes corrupted, and inaccessible for host input/output I/O data, if the following conditions are true:

- A changed volume is part of an `idling` relationship.
- The changed volume is being used for secondary protection.
- The background copy process is still migrating the change volume data to the secondary volume.

You must run the **recovervdisk** command to regain access to the volume contents. If all of the following conditions are true, the secondary volume also becomes corrupted:

- The change volume was part of an `idling` relationship.
- The change volume was being used for a Global Mirror relationship that uses multicycling mode.
- The relationship was deleted, but the background copy process continued and is still migrating data to the secondary volume.

In any of these cases, this **recovervdisk** command fails unless you specify the **-force** parameter.

Note:

- The **-force** parameter must be used if **rmvdisk** is specified and rejected if the volume is a change volume for a relationship.
- If the volume is a change volume for a relationship, specifying **rmvdisk** with **-force** removes the change volume from the relationship.

An invocation example

```
rmvdisk -force vdisk5
```

The resulting output:

```
No feedback
```

An invocation example

```
rmvdisk -removehostmappings vdisk3
```

The resulting output:

```
No feedback
```

addvolumecopy

Use the **addvolumecopy** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdiskcopy

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolumecopy** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairvdiskcopyprogress

The **lsrepairvdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolume group

Use the **mkvolume group** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of `corrupt` and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of `corrupt` and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

[rmvdiskhostmap](#)

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

[rmvolume](#)

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumeecopy](#)

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolumegroup](#)

Use the **rmvolumegroup** command to remove a volume group from a system.

[rmvolumebackupgeneration](#)

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdiskspace](#)

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

Syntax

➡ **rmmetadatavdisk** 

Parameters

-ignorevvsexist

(Optional) Specifies that you want the system to delete the metadata volume (including volumes with owner type `vvol`).

Description

This command removes the metadata volume from a storage pool.

When **-ignorevvsexist** is specified, only the metadata volume is deleted. Additionally, volumes with owner type `vvol` are not affected.

An invocation example

```
rmmetadatavdisk -ignorevvsexist
```

The resulting output:

```
No feedback
```

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeegroup

Use the **rmvolumeegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

Syntax

➡ **rmvdiskcopy** — **-copy** — *copy_id* — **-force** — *vdisk_name* — **-vdisk_id** ➡

Parameters

-copy *copy_id*

(Required) Specifies the ID of the copy to delete.

-force

(Optional) Forces the deletion of the last synchronized copy of a volume, which deletes the entire volume.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of IBM support personnel.

The parameter also forces the deletion of a nonmirrored volume, a copy that is migrating to image mode, or an image-mode copy that has virtual medium errors.

Important: To prevent an active volume from being deleted unintentionally, you can use a global system setting to enable volume protection (see the **chssystem** command). You can specify a time period for which the volume must be idle before you can delete it. If volume protection is enabled and the time period has not expired, the volume deletion fails even if the **-force** parameter is used.

Note: When you use the **-force** parameter to delete a synchronized copy from a mirrored volume, where the synchronized copy is in a storage pool with volume protection inactive, but it has an unsynchronized copy in a different storage pool with volume protection active, then volume protection applies to the volume. It is because the unsynchronized copy is also deleted and it is in a storage pool

with volume protection active, as the **-force** is deleting both copies in a mirrored volume the command fails if host I/O is being sent to the volume in the defined volume protection time period.

vdisk_name / vdisk_id

(Required) Specifies the volume to delete the copy from. You must specify this parameter last on the command line.

Description

The **rmvdiskcopy** command deletes the specified copy from the specified volume. The command fails if all other copies of the volume are not synchronized; in this case, you must specify the **-force** parameter, delete the volume or more, or wait until the copies are synchronized.

Remember: This command is unsuccessful if:

- Volume protection is enabled
- The last volume copy being deleted has received I/O within the defined volume protection time period

These changes apply to this command only when deleting the last synchronized copy of a volume or removing the entire volume.

An invocation example

This example forces a deletion.

Important: Using the force parameter might result in a loss of access. Use it only under the direction of your product support information.

```
rmvdiskcopy -copy 0 -force 134
```

The resulting output:

```
No feedback
```

An invocation example

This example deletes a mirrored copy from a volume, where 1 is the ID of the copy to delete and vdisk8 is the volume to delete the copy from.

```
rmvdiskcopy -copy 1 vdisk8
```

The resulting output:

```
No feedback
```

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume group

Use the **rmvolume** command to remove a volume group from a system.

[rmvolumebackupgeneration](#)

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdiskspace](#)

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

[splitvdiskspace](#)

Use the **splitvdiskspace** command to create a separate volume from a synchronized copy of a mirrored volume.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

Syntax

```
➔ rmvdiskaccess — -iogrp iogrp_id_list vdisk_id
                                     | iogrp_name_list | vdisk_name ➔
```

Parameters

-iogrp *iogrp_id_list* | *iogrp_name_list*

(Required) Specifies a list of I/O groups to remove from the I/O group access set of the volume.

vdisk_id* | *vdisk_name

(Required) Specifies the volume from which to remove access I/O groups.

Description

The **rmvdiskaccess** command removes I/O groups from the volume access set. However, it cannot remove all I/O groups from the access set; a volume must have at least one I/O group in an access set. When an I/O group is removed from the access set, all host mappings created through that I/O group (for the volume) are deleted. Consequently, you cannot access the volume through any related I/O group nodes.

Remember: If an I/O group in the list is not in the access set, no error is generated, but no action is taken for that I/O group.

An invocation example to remove I/O groups 2 and 3 from the volume access set for volume ID 3

```
rmvdiskaccess -iogrp 2:3 3
```

The resulting output:

```
No feedback
```

[addvolume](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdiskcopy](#)

Use the **addvdiskcopy** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolume**group command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolume**group command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisk** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdisk**map command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavd**isk command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdisk**copyprogress command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdisk**copyprogress command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdisk**copy command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdisk**access command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmapcopies

Use the **lsvdiskfcmapcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations.

Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolume group

Use the **mkvolume group** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

Syntax

rmvdiskhostmap — -host host_id vdisk_id

host name vdisk name

Parameters

-host *host_id / host_name*

(Required) Specifies the host that you want to remove from the map with the volume, either by ID or by name.

vdisk_id / vdisk_name

(Required) Specifies the name of the volume that you want to remove from the host mapping, either by ID or by name.

Description

This command deletes an existing mapping between the specified volume and the host. This effectively stops the volume from being available for I/O transactions on the given host.

This command also deletes a Small Computer System Interface (SCSI) or persistent reservation that a host has on a volume. Once the reservation is removed, a new host is allowed to access the volume in the future because the original host no longer has access.

Note: The **rmvdiskhostmap** command deletes the host mapping for all I/O groups in the access I/O group set of the volume.

Use caution when you process this command because to the host, it seems as if the volume has been deleted or is offline.

Remember: This command is unsuccessful if:

- Volume protection is enabled

- The host mapping being deleted is mapped to any volume that has received I/O within the defined volume protection time period

An invocation example

```
rmvdiskhostmap -host host1 vdisk8
```

The resulting output:

```
No feedback
```

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisks that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsdisksyncprogress

Use the **lsdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumegroup

Use the **lsvolumegroup** command to display information about configured volume groups.

lsvolumerestoreprogress

Use the **lsvolumerestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes stretched and hyperswap topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolumegroup

Use the **mkvolumegroup** command to create and configure a new volume group.

mkimagevolume

Use the **mkimagevolume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a `fast_write_state` of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a `fast_write_state` of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadavdisk

Use the **rmmetadavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type `host_integration_metadata`) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

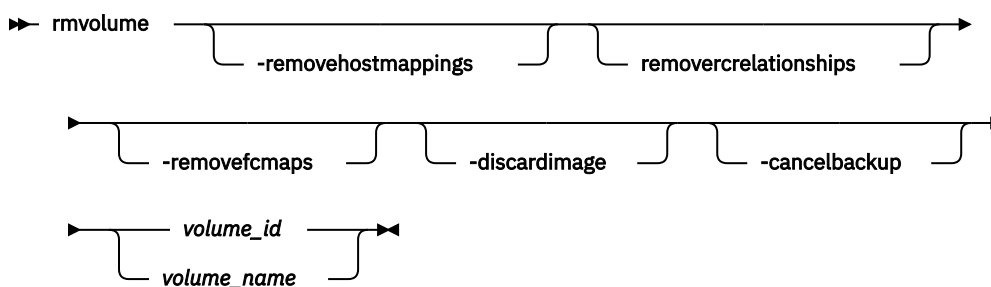

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

Syntax

Parameters

-removehostmappings

(Optional) Allows a volume to be deleted even if host mappings are removed if this volume is deleted.

-removercrelationships

(Optional) Allows a volume to be deleted even if it is part of a remote copy relationship.

-removefcmaps

(Optional) Allows a volume to be deleted even if it is part of a FlashCopy mapping and regardless of the state of the mappings. FlashCopy mappings that are `rc_controlled` (for change volumes) require this parameter to be specified to force the deletion of a change volume while it is configured in a remote copy relationship. However, it is recommended to remove the change volume from the relationship before you delete it to avoid data loss. HyperSwap volumes with only the `rc_controlled` FlashCopy mappings for change volumes do not require this parameter to be specified.

-discardimage

(Optional) Allows a volume to be deleted even if data on an image mode copy cannot be made consistent.

Important: Using this parameter might result in data loss. Use it only under the direction of your product support information, or if you are willing to accept the risk of data loss on the volume.

-cancelbackup

(Optional) Allows a volume to be deleted even if a backup operation is in progress.

Important: Using this parameter might result in data loss. Use it only under the direction of your product support information, or if you are willing to accept the risk of data loss on the volume.

volume_id / volume_name

(Required) Specifies the volume to be removed.

Description

Use the **rmvolume** command to remove a volume.

For a HyperSwap volume, the active-active relationship and the change volumes are also deleted.

An invocation example to remove a volume

```
rmvolume 0
```

The detailed resulting output:

```
No feedback
```

An invocation example to remove a volume with FlashCopy mappings

```
rmvolume -removefcmaps 1
```

The detailed resulting output:

```
No feedback
```

An invocation example to remove a master or auxiliary volume in a Global Mirror relationship with change volumes

```
rmvolume -removercrelationships 6
```

The detailed resulting output:

```
No feedback
```

An invocation example to remove a HyperSwap volume

```
rmvolume myhyperswapvol
```

[rmvdiskhostmap](#)

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

[rmvolume](#)[copy](#)

Use the **rmvolume****copy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolume](#)[group](#)

Use the **rmvolume****group** command to remove a volume group from a system.

[rmvolume](#)[backup](#)[generation](#)

Use the **rmvolume****backup****generation** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdisksize](#)

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

Syntax

This syntax diagram specifies a volume copy by site.

This syntax diagram specifies a volume copy by copy ID or storage pool. You must specify either **-copy** or **-pool**.

Parameters

-site *site_id* / *site_name*

(Required) Specifies the site that the volume copy is removed from. You cannot specify this parameter if you specify **-copy** or **-pool**.

-pool *storage_pool_id* / *storage_pool_name*

(Optional) Specifies the storage pool that the volume copy is removed from.

-copy *copy_id*

(Optional) Specifies the copy ID for the volume copy to be deleted. The value is 0 or 1. This keyword cannot be specified when **-site** is specified.

Important: If the volume has copies in multiple sites you must specify **-pool** to identify the volume copy to remove.

You must specify either **-copy** or **-pool**.

-removefcmaps

(Optional) Allows a volume copy to be deleted even if it is part of a FlashCopy mapping.

Important: Use this parameter for HyperSwap volumes.

You must specify either **-copy** or **-pool**.

-discardimage

(Optional) Allows a volume copy to be deleted even if data on an image mode copy cannot be made consistent.

Important: Using this parameter might result in data loss. Use it only under the direction of your product support information, or if you are willing to accept the risk of data loss on the volume.

volume_id / volume_name

(Required) Specifies the volume ID or name for the volume copy to remove. The value for volume ID must be a number and the value for volume name must be an alphanumeric string.

Description

Use the **rmvolume** command to remove a copy of a volume.

For a HyperSwap volume, the active-active relationship and the change volumes are also deleted.

Remember: HyperSwap volumes that are part of a consistency group must be removed from that consistency group before you can remove the last volume copy from that site.

This command fails if a backup operation is in progress.

An invocation example to remove a volume copy at site 1 on a HyperSwap system

```
rmvolume -site 1 0
```

The detailed resulting output:

```
No feedback
```

An invocation example to remove a volume copy when there are two copies in the same storage pool.

```
rmvolume -pool 5 -copy 1 volume5
```

The detailed resulting output:

```
No feedback
```

An invocation example to remove a volume copy with FlashCopy mappings.

```
rmvolume -site 1 -removefcmaps 1
```

The detailed resulting output:

```
No feedback
```

Related reference**addvolume**

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

addvdisk

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

addvdiskaccess

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

analyzevdisk

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisks

Use the **lsdependentvdisks** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsvdisk

Use the **lsvdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsvdiskaccess

Use the **lsvdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsvdiskanalysis

Use the **lsvdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsvdiskanalysisprogress

Use the **lsvdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsvdiskcopy

Use the **lsvdiskcopy** command to list volume copy information.

lsvdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappcopies

Use the **lsvdiskfcmappcopies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolume group

Use the **mkvolume group** command to create and configure a new volume group.

mkimage volume

Use the **mkimage volume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume group

Use the **rmvolumegroup** command to remove a volume group from a system.

[rmvolumebackupgeneration](#)

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[shrinkvdiskspace](#)

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

Syntax

➔ **rmvolumegroup** 

Parameters

volumegroup_name / volumegroup_id

(Required) Specifies the volume group name or ID for the volume to remove from the system. The value for the volume group ID must be a number and the value for the volume group name must be an alphanumeric string.

Description

This command removes a volume group from a system.

Note: You cannot delete a volume group if it contains active volumes.

An invocation example

```
rmvolumegroup Vardy1
```

The resulting output:

```
No feedback
```

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume copy

Use the **rmvolume** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdiskspace

Use the **shrinkvdiskspace** command to reduce the size of a volume by the specified capacity.

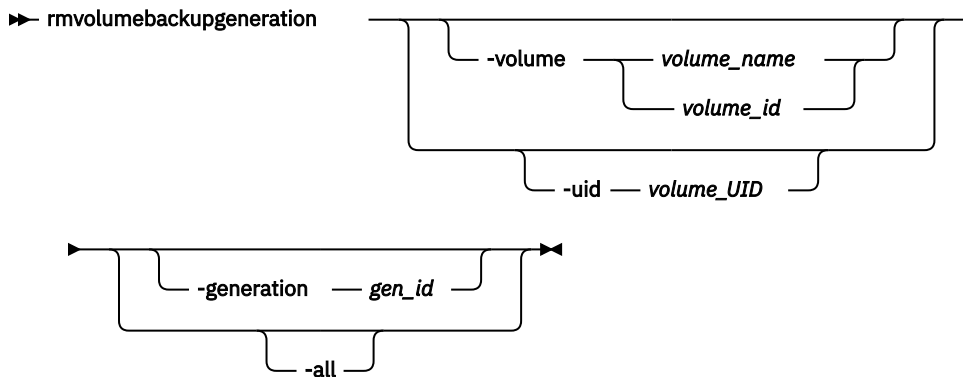

splitvdiskspace

Use the **splitvdiskspace** command to create a separate volume from a synchronized copy of a mirrored volume.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

Syntax

Parameters

-volume volume_name / volume_id

(Optional) Specifies the volume snapshot by name or ID.

Note: The volume must exist on the local system.

The value for the volume name must be an alphanumeric string and the value for the volume ID must be a number. This parameter is mutually exclusive with **-uid**.

-uid volume_UID

(Optional) Specifies the volume snapshot UID. The value for a volume UID must be a number 0 - 32. This parameter is mutually exclusive with **-volume**.

-generation gen_id

(Optional) Specifies the snapshot generation to be deleted for the volume. Only a single snapshot generation is deleted. If the specified generation is for a snapshot operation that is in progress, that snapshot operation is canceled. The value for the generation ID must be a number. This command is mutually exclusive with **-all**.

-all

(Optional) Specifies deletion for all volume snapshots (which cancels all snapshot generations as well). This command is mutually exclusive with **-generation**.

Description

This command deletes a volume snapshot or cancels a volume snapshot operation that is in progress.

Note: If the:

- Command completes immediately, the delete operation is performed asynchronously
- Volume has more than one snapshot generation, you cannot delete the most recent snapshot generation

An invocation example

To delete snapshot generation 22 for volume with the UID 600507680CA880DF18000000000000007:

```
rmvolumebackupgeneration -uid 600507680CA880DF18000000000000007 -generation 22
```

The resulting output:

```
No feedback
```

An invocation example

To cancel the current snapshot generation 5 that is in progress for volume vdisk7:

```
rmvolumebackupgeneration -volume vdisk7 -generation 5
```

The resulting output:

```
No feedback
```

An invocation example

To remove all volume snapshots with the name vdisk10:

```
rmvolumebackupgeneration -volume vdisk10 -all
```

The resulting output:

```
No feedback
```

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumecopy

Use the **rmvolumecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

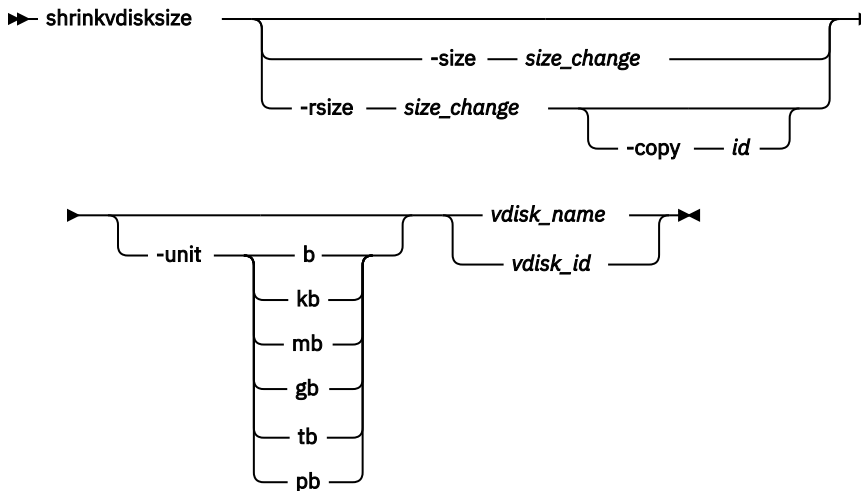

[splitvdiskcopy](#)

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

Syntax

Parameters

-size size_change

(Optional) Specifies the size reduction (change in size) for the designated volume. The **-size** parameter cannot be used with the **-rsize** parameter. You must specify either **-size** or **-rsize**.

Important: This parameter does reduce the size of a volume (the specified virtual size capacity).

Remember: You cannot use **-size** to resize a thin-provisioned or compressed volume copy that is in a data reduction pool.

-rsize size_change

(Optional) Reduces the real size of a thin-provisioned volume by the specified amount. It indicates the change in size as a result of the reduction. Specify the *size_change* value by using an integer. Specify the units for a *size_change* integer by using the **-unit** parameter; the default is MB. You must specify either **-rsize** or **-size**.

Remember: You cannot use **-rsize** to resize a thin-provisioned or compressed volume copy that is in a data reduction pool.

-copy id

(Optional) Specifies the copy to change the real capacity for. You must also specify the **-rsize** parameter. If the **-copy** parameter is not specified, all copies of the volume are reduced. This parameter is required if the volume is mirrored and only one copy is thin-provisioned.

-unit b | kb | mb | gb | tb | pb

(Optional) Specifies the data units to be used along with the value that is specified by the **-size** parameter.

vdisk_name / vdisk_id

(Required) Specifies the volume that you want to modify, either by ID or by name.

Description

The **shrinkvdisksize** command reduces the capacity that is allocated to the particular volume by the amount that you specify. You cannot shrink the real size of a thin-provisioned volume below its used size. All capacities, including changes, must be in multiples of 512 bytes. An entire extent is reserved even if it is only partially used. The default capacity units are MB. You cannot use **shrinkvdisksize** if the volume is fast formatting.

The command can be used to shrink the usable capacity that is allocated to a particular volume by the specified amount. The command can also be used to shrink the provisioned capacity of a thin-provisioned volume without altering the usable capacity that is assigned to the volume. To change the capacity of a non-thin-provisioned disk, use the **-size** parameter. To change the real capacity of a thin-provisioned disk, use the **-rsize** parameter. To change the provisioned capacity of a thin-provisioned disk, use the **-size** parameter.

Volumes can be reduced in size, if required.

When the virtual size of a thin-provisioned volume is changed, the warning threshold is automatically scaled to match. The new threshold is stored as a percentage.

To run the **shrinkvdisksize** command on a mirrored volume, all copies of the volume must be synchronized.

Attention: If the volume contains data that is being used, do not shrink the volume without backing up the data first.

The system reduces the capacity by removing extents that are allocated to the end of the volume. You cannot control how the host used the capacity that was provisioned to it and so you cannot assume that the unused space is all at the end of the volume.

Remember: Before you shrink a volume, validate that the volume is not mapped to any host objects.

You can determine the exact capacity of the source or master volume by issuing the **lsvdisk -bytes vdiskname** command. Shrink the volume by the required amount by issuing the **shrinkvdisksize -size size_change-unit b | kb | mb | gb | tb | pb vdisk_name | vdisk_id** command.

Remember:

1. You cannot resize (shrink) an image mode volume.
2. You cannot resize (shrink) the disk if the volume contains data.
3. You cannot resize (shrink) a volume that is part of a file system.
4. You cannot resize (shrink) volume if that volume is being formatted.
5. You cannot resize (shrink) a volume that is being migrated.
6. You cannot resize (shrink) a volume if cloud snapshot is enabled on that volume.

This command is supported for volumes in Metro Mirror and Global Mirror relationships that are in `consistent_synchronized` state if those volumes are using thin-provisioned or compressed copies.

This command is not supported for volumes:

- In HyperSwap relationships or in Global Mirror relationships that are operating in `cycling` mode.
- In relationships that have a change volume configured.
- Mirrored volumes that have at least one `standard-provisioned` copy.

You must shrink both volumes in a relationship to maintain full operation of the system. To perform this task:

1. Shrink the secondary volume by the required capacity.
2. Shrink the primary volume by the required capacity.

You cannot shrink the virtual size (specified by using the **-size** parameter) for thin or compressed volumes in data reduction storage pools. The exception to this is to permit a shrink after you expand the volume if the expanded space has not yet been written to.

An invocation example to decrease the capacity of vdisk1 by 2 KB

```
shrinkvdiskspace -size 2048 -unit b vdisk1
```

The resulting output:

```
No feedback
```

An invocation example to decrease the capacity of vdisk2 by 100 MB

```
shrinkvdiskspace -size 100 -unit mb vdisk2
```

The resulting output:

```
No feedback
```

An invocation example to decrease the real capacity of thin-provisioned vdisk3 by 100 MB without changing its provisioned capacity

```
shrinkvdiskspace -rsize 100 -unit mb vdisk3
```

The resulting output:

```
No feedback
```

An invocation example to decrease the real capacity of thin-provisioned VDisk copy ID 1 of mirrored vdisk3 by 100 MB

```
shrinkvdiskspace -rsize 100 -unit mb -copy 1 vdisk4
```

The resulting output:

```
No feedback
```

An invocation example to decrease the provisioned capacity of thin-provisioned vdisk5 by 1 GB without changing its real capacity

```
shrinkvdiskspace -size 1 -unit gb vdisk5
```

The resulting output:

```
No feedback
```

[addvolume](#)

Use the **addvolume** command to add a copy to an existing volume. On a standard topology system, you can use this command to add a mirrored copy to an existing volume. On a stretched or HyperSwap topology system, you can use this command to convert an existing basic volume into a highly available volume by adding a copy of that volume at a second site.

[addvdisk](#)

Use the **addvdisk** command to add a copy to an existing volume, which changes a nonmirrored volume into a mirrored volume. On a system with a hyperswap topology, use the **addvolume** command to convert an existing volume to a HyperSwap volume by adding a copy at a second site.

[addvdiskaccess](#)

Use the **addvdiskaccess** command to add an I/O group (or groups) to the set of I/O groups in which a volume can be made accessible to hosts.

[analyzevdisk](#)

Use the **analyzevdisk** command to queue or cancel volume analysis.

analyzevdiskbysystem

Use the **analyzevdiskbysystem** command to schedule all existing volumes in system for [available capacity](#) analysis.

backupvolume

Use the **backupvolume** command to create a volume snapshot.

backupvolumegroup

Use the **backupvolumegroup** command to create a new snapshot for all of the volumes in a volume group.

chvdisk

Use the **chvdisk** command to modify the properties of a volume, such as the disk name, I/O governing rate, or unit number. You can also change IBM Easy Tier settings.

chvolumegroup

Use the **chvolumegroup** command to change volume group properties.

expandvdisksize

Use the **expandvdisksize** command to expand the provisioned capacity of a volume by a specified amount.

expandvolume

Use the **expandvolume** command to expand the size of a HyperSwap volume by a specified capacity.

lsdependentvdisk

Use the **lsdependentvdisk** command to view which volumes go offline if you remove a specific piece of hardware from the system.

lshostvdiskmap

Use the **lshostvdiskmap** command to display a list of volumes that are mapped to a host. These volumes are the volumes that are recognized by the specified host.

lsmetadatavdisk

Use the **lsmetadatavdisk** command to display the information for metadata volume.

lsrepairsevdiskcopyprogress

The **lsrepairsevdiskcopyprogress** command lists the repair progress for thin-provisioned volume copies or compressed volume copies.

lsrepairvdiskcopyprogress

Use the **lsrepairvdiskcopyprogress** command to display the progress of volume repairs and validations.

lssevdiskcopy

Use the **lssevdiskcopy** command to list the thin-provisioned copies of the specified volumes.

lsdisk

Use the **lsdisk** command to display a concise list or a detailed view of volumes that are recognized by the system.

lsdiskaccess

Use the **lsdiskaccess** command to display a list of all input/output (I/O) groups in the volume access set.

lsdiskanalysis

Use the **lsdiskanalysis** command to display information for thin provisioning and compression estimation analysis report for a single volume or multiple volumes.

lsdiskanalysisprogress

Use the **lsdiskanalysisprogress** command to display information about the space analysis progress for an entire system.

lsdiskcopy

Use the **lsdiskcopy** command to list volume copy information.

lsdiskdependentmaps

Use the **lsvdiskdependentmaps** command to display all FlashCopy mappings with target volumes that are dependent upon data that is held on the specified volume.

lsvdiskextent

Use the **lsvdiskextent** command to list the MDisk extents that are provided for the specified volumes.

lsvdiskfcmappointies

Use the **lsvdiskfcmappointies** command to display a list of all FlashCopy mappings with a target volume that contains a valid copy of the specified volume.

lsvdiskfcmappings

Use the **lsvdiskfcmappings** command to display a list of FlashCopy mappings to which the volume belongs. A volume can be part of up to 256 FlashCopy mappings.

lsvdiskhostmap

Use the **lsvdiskhostmap** command to list the hosts to which a volume is mapped.

lsvdisklba

Use the **lsvdisklba** command to list the volume and logical block address (LBA) for the specified storage pool LBA.

lsvdiskmember

Use the **lsvdiskmember** command to display a list of MDisk that are members of the specified volume.

lsvdiskprogress

Use the **lsvdiskprogress** command to track the progress during new volume formatting.

lsvdisksyncprogress

Use the **lsvdisksyncprogress** command to display the progress of volume copy synchronization.

lsvolumebackup

Use the **lsvolumebackup** command to list the volumes that have cloud snapshot that enabled and volumes that have cloud snapshots in the cloud account.

lsvolumebackupgeneration

Use the **lsvolumebackupgeneration** command to list any volume snapshots available on the specified volume.

lsvolumebackupprogress

Use the **lsvolumebackupprogress** command to display information about the progress of snapshot operations.

lsvolumebackupgroup

Use the **lsvolumebackupgroup** command to display information about configured volume groups.

lsvolumebackuprestoreprogress

Use the **lsvolumebackuprestoreprogress** command to display information about restore operation progress.

mkmetadatavdisk

Use the **mkmetadatavdisk** command to create one metadata volume (owner type is `host_integration_metadata`) from a storage pool. You can also export one block device or file system (that is based on this volume) in the configuration node.

mkvdisk

Use the **mkvdisk** command to create sequential, striped, or image mode volume objects. When they are mapped to a host object, these objects are seen as disk drives with which the host can run I/O operations. Note the first syntax diagram below is for striped or sequential volumes and the second syntax diagram is for image mode volumes. Use the **mkvolume** command for a simplified way of creating high availability volumes. It includes `stretched` and `hyperswap` topologies. Use the **mkimagevolume** command for a simplified way of creating an image mode volume, importing existing data from a managed disk.

mkvdiskhostmap

Use the **mkvdiskhostmap** command to create a new mapping between a volume and a host, which makes the volume accessible for input/output (I/O) operations to the specified host.

mkvolume

Use the **mkvolume** command to create an empty volume from existing storage pools. You can use this command for high availability configurations that include HyperSwap or stretched systems, but it can also be used for volumes that are not high availability.

mkvolume group

Use the **mkvolume group** command to create and configure a new volume group.

mkimage volume

Use the **mkimage volume** command to create an image mode volume by importing (preserving) data on a managed disk from another storage system.

movevdisk

Use the **movevdisk** command to move the preferred node of a volume either within the same caching I/O group or to another caching I/O group.

recovervdisk

Use the **recovervdisk** command to acknowledge volume data loss and brings the volume back online.

recovervdiskbycluster (Discontinued)

Attention: The **recovervdiskbycluster** command has been discontinued. Use the **recovervdiskbysystem** command instead.

recovervdiskbyiogrp

Use the **recovervdiskbyiogrp** command to acknowledge data loss for all volumes in the specified I/O group with a fast_write_state of corrupt and brings the volumes back online.

recovervdiskbysystem

Use the **recovervdiskbysystem** command to acknowledge data loss for all volumes in the system with a fast_write_state of corrupt and bring the volumes back online.

repairsevdiskcopy

The **repairsevdiskcopy** command repairs the metadata on a thin-provisioned volume copy or a compressed volume copy.

repairvdiskcopy

Use the **repairvdiskcopy** command on mirrored volumes to detect and (optionally) correct any volume copies that are not identical.

restorevolume

Use the **restorevolume** command to restore a volume from a snapshot generation.

rmvdisk

Use the **rmvdisk** command to delete a volume. This command cannot be used for high availability volumes. Use the **rmvolume** command for high availability volumes.

rmmetadatavdisk

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolume copy

Use the **rmvolume** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

[rmvolume group](#)

Use the **rmvolume group** command to remove a volume group from a system.

[rmvolume backup generation](#)

Use the **rmvolume backup generation** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

[splitvdiskcopy](#)

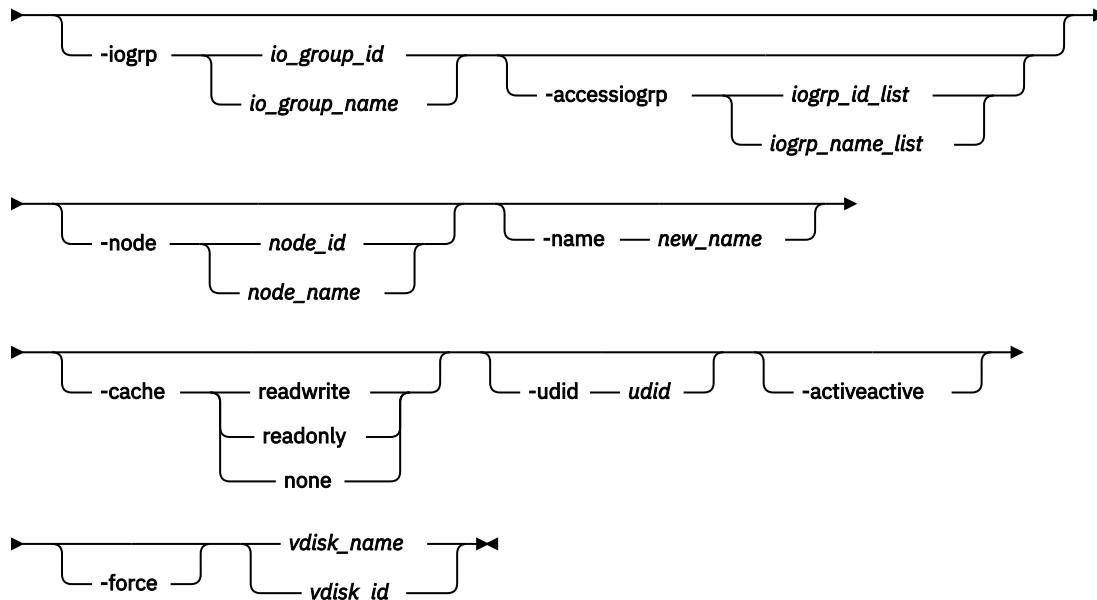

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

splitvdiskcopy

Use the **splitvdiskcopy** command to create a separate volume from a synchronized copy of a mirrored volume.

Syntax

►► **splitvdiskcopy** — **-copy** — *id* →

Parameters

-copy id

(Required) Specifies the ID of the copy to split.

-iogrp io_group_id / io_group_name

(Optional) Specifies the I/O group to add the new volume to. The default is the I/O group of the specified volume.

-accessiogrp iogroup_id_list / iogroup_name_list

(Optional) Specifies which I/O groups provide access to the volume. If the **-accessiogrp** parameter is used, the **-iogrp** parameter must also be specified. The specified volume access set must include the caching I/O group. If the **-accessiogrp** parameter is not specified, the new volume is assigned its caching I/O group as the only I/O group that provides access, where the caching I/O group is assigned by the system or by using **-iogrp**.

-node *node_id* / *node_name*

(Optional) Specifies the preferred node ID or the name for I/O operations to this volume. You can use the **-node** parameter to specify the preferred access node.

-name *new_name*

(Optional) Assigns a name to the new volume.

-cache *readwrite* | *readonly* | *none*

(Optional) Specifies the caching options for the new volume. (Optional) Specifies the caching options for the volume. Valid entries are:

- *readwrite* to enable the cache for the volume
- *readonly* to disable write caching while allowing read caching for a volume
- *none* to disable the cache mode for the volume

The default is *readwrite*.

Remember: If you do not specify the **-cache** parameter, the default value (*readwrite*) is used.

-udid *udid*

(Optional) Specifies the *udid* for the new volume. The *udid* is a required identifier for OpenVMS hosts; no other hosts use this parameter. Supported values are a decimal number 0 - 32767, or a hexadecimal number 0 - 0x7FFF. A hexadecimal number must be preceded by 0x; for example, 0x1234. The default *udid* value is 0.

-activeactive

(Optional) Specifies that an active-active relationship is created between the specified volume and the newly created volume.

-force

(Optional) Allows the split to proceed even when the specified copy is not synchronized, or even when the cache flush is likely to fail. The newly created volume might not be consistent.

Description

The **splitvdiskcopy** command creates a new volume in the specified I/O Group from a copy of the specified volume.

For thin or compressed volumes that are in data reduction storage pools:

- You cannot specify a cache mode of *none* or *readonly*.
- You cannot specify an I/O group that is different from the current I/O group that is associated with the volume.

If the copy that you are splitting is not synchronized, you must use the **-force** parameter. The command fails if you are attempting to remove the only synchronized copy. To avoid command failure, wait for the copy to synchronize or split the unsynchronized copy from the volume by using the **-force** parameter. You can run the command when either volume copy is offline.

For active-active relationships, the existing volume must be in an I/O group with a site name or site ID. The existing volume must also use a storage pool with the same site information. The new volume must be created in an I/O group with a site name or site ID (that is not the same site as the I/O group for the existing volume). The new volume must use a storage pool with the same site name or site ID as the I/O group's site name or site ID. The topology must be hyperswap or the active-active relationship is not allowed.

For active-active relationships, the existing volume must not be the target of a FlashCopy mapping.

You can use this command to partially create a HyperSwap volume and:

- Configure the access I/O groups for the existing volume to include the new volume's I/O group.
- Create and associate change volumes to the active-active relationship.

When these tasks are completed, the active-active relationship can start or resynchronize any regions that are written to on the existing volume. The created relationship uses the existing volume as its master copy, and the new volume as its auxiliary copy.

Note: If the I/O group has enough bitmap space available to allocate for remote copy and the allocated space for the remote copy is not large enough to accommodate the new relationship, space is automatically added. (Remote copy includes Global Mirror, Metro Mirror, and active-active relationships.)

An invocation example for creating a volume with I/O groups 2 and 3 in its I/O group access set

```
splitvdiskcopy -copy 1 -iogrp 2 -node 7 -accessiogrp 2:3 DB_Disk
```

The resulting output:

```
Virtual Disk, copy [1], successfully created.
```

An invocation example

```
splitvdiskcopy -copy 1 vdisk8
```

The resulting output:

```
Virtual Disk, id [1], successfully created.
```

An invocation example

```
splitvdiskcopy -activeactive -iogrp siteB -copy 1 -name siteBvolume siteAvolume
```

The resulting output:

```
Virtual Disk, copy [1], successfully created.
```

Use the **rmmetadatavdisk** command to detach a file system or remove a block device (that is based on the volume with owner type host_integration_metadata) in a configuration node.

rmvdiskcopy

Use the **rmvdiskcopy** command to remove a volume copy from a volume. This command cannot be used for high availability volumes.

rmvdiskaccess

Use the **rmvdiskaccess** command to delete one or more I/O groups from the set of I/O groups in which a volume can be made accessible to hosts.

rmvdiskhostmap

Use the **rmvdiskhostmap** command to delete an existing host mapping the volume is no longer accessible for input/output (I/O) transactions on the given host.

rmvolume

Use the **rmvolume** command to remove a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumeecopy

Use the **rmvolumeecopy** command to remove a volume copy from a volume. You can use this command for high availability configurations that include HyperSwap or stretched systems.

rmvolumegroup

Use the **rmvolumegroup** command to remove a volume group from a system.

rmvolumebackupgeneration

Use the **rmvolumebackupgeneration** command to delete a volume backup or cancel a volume snapshot operation that is in progress.

shrinkvdisksize

Use the **shrinkvdisksize** command to reduce the size of a volume by the specified capacity.

Chapter 31. Command-line interface messages

The messages that display when you use the command-line interface (CLI) are listed here.

The CLI displays a return value upon completion of the command. If the command completes normally and without error, the return code is 0. If the command fails, the return code is **1** and the Error Code is sent to standard error. If the command succeeds, but the cluster is operating near its licensed virtualization limit, the return code can still be 1, and a warning Error Code is sent to standard error.

When you issue a **create** command, the message ID that is assigned to the new object is returned as part of the success message that is sent to standard output. If the **-quiet** parameter is used, only the message ID is sent.

Command-line interface messages

CLI messages are listed in alphanumeric order.

CLI message reference

CLI messages are listed in alphanumeric order.

CMMVC4041E You must use an 0x parameter for the -lba and -vdisklba parameters.

Explanation:

The parameter format for lsmdisklba needs explaining if using the incorrect format.

User response:

Retry the command using the described parameter format.

CMMVC4042E You must use an 0x parameter for the -lba and -mdisklba parameters.

Explanation:

The parameter format for lsmdisklba needs explaining if using the incorrect format.

User response:

Retry the command using the described parameter format.

CMMVC4043E You must use an 0x parameter for the -mdisklba parameter.

Explanation:

The parameter format for lsmdisklba needs explaining if using the incorrect format.

User response:

Retry the command using the described parameter format.

CMMVC4044E You must use an 0x parameter for the -drivelba parameter.

Explanation:

The parameter format for lsmdisklba needs explaining if using the incorrect format.

User response:

Retry the command using the described parameter format.

CMMVC5000I No message was found for major rc *MAJOR_RC* , minor rc *MINOR_RC* , for action/view id *ACTION_VIEW_ID* .

Explanation

A message is missing.

User response

Contact the support center.

CMMVC5700E The parameter list is not valid.

Explanation

You have entered a list of parameters that is not supported for the command.

User response

Specify a parameter list that is supported for the command, and resubmit the command.

CMMVC5701E No object ID was specified.

Explanation

The command that you have submitted requires that you specify an object identifier name or ID number, and you did not specify an object identifier.

User response

Specify an object ID, and resubmit the command.

CMMVC5702E **VALUE is below the minimum level.**

Explanation

You entered the specified string as a value for a parameter. The parameter requires a minimum value, and the specified string is less than the required minimum value.

User response

Specify a value that is supported by the parameter, and resubmit the command.

CMMVC5703E **The value or list starting with VALUE is above the maximum permitted for that value or has exceeded the number of items allowed in a list.**

Explanation

The specified string was entered as a value for a parameter. The string is either a stand-alone value or the first value in a list of values. If the string is a stand-alone value, the value is greater than the supported maximum value for the parameter. If the string is the first value in a list of values, the list contains more than the supported maximum number of entries for the parameter.

This error can occur after the **svctask chsystemethernet** command is run, if Ethernet traffic priority values are specified that are not integers in the range 0 - 7.

User response

Specify a value or list of values that is supported by the parameter, and resubmit the command.

CMMVC5704E **VALUE is not divisible by the permitted step value.**

Explanation

You have entered the specified string as a value for a parameter. The string is not a supported value for the parameter. One requirement is that the value is an even multiple of 16, and the specified string does not meet that requirement.

User response

Specify a value that is supported by the parameter, and resubmit the command.

CMMVC5705E **A required parameter is missing.**

Explanation

The command that you have submitted has at least one required parameter that you have not entered.

User response

Specify all of the required parameters, and resubmit the command.

CMMVC5706E **An invalid argument has been entered for the PARAMETER parameter.**

Explanation

You have entered a value for the specified parameter and the value is not supported for the parameter. The parameter supports a specific set of values.

User response

Specify a value that is supported by the parameter, and resubmit the command.

CMMVC5707E **Required parameters are missing.**

Explanation

The command that you have submitted has more than one required parameter that you have not entered.

User response

Specify all of the required parameters, and resubmit the command.

CMMVC5708E **The PARAMETER parameter is missing its associated arguments.**

Explanation

You have entered the specified parameter without an associated value. This parameter, like most parameters, requires an associated value.

User response

Specify the associated value, and resubmit the command.

CMMVC5709E **VALUE is not a supported parameter.**

Explanation

The specified string is not a supported parameter for the command that you have entered.

User response

Specify the correct parameter, and resubmit the command.

CMMVC5711E **VALUE is not valid data.**

Explanation

You have entered the specified string as a value for a parameter. The string is not a supported value for the parameter (for example, the specified string is an incorrect path).

User response

Specify a value that is supported by the parameter, and resubmit the command.

CMMVC5712E **Required data is missing.**

Explanation

You have entered an incomplete command.

User response

Specify command completely, and resubmit the command.

CMMVC5713E **Some parameters are mutually exclusive.**

Explanation

Certain commands have two or more parameters that are mutually exclusive. You have submitted a command using at least two mutually exclusive parameters.

User response

Specify a supported combination of parameters, and resubmit the command.

CMMVC5714E **The parameter list is empty.**

Explanation

Certain parameters require one or more values in a colon separated parameter list. You have specified at least one parameter without the required parameter list.

User response

Specify at least one value for all parameters that require a value, and resubmit the command.

CMMVC5715E **The parameter list does not exist.**

Explanation

Certain parameters require one or more values in a colon separated parameter list. You have specified at least one parameter without the required parameter list.

User response

Specify at least one value for all parameters that require a value, and resubmit the command.

CMMVC5716E **Non-numeric data was entered for the numeric field *FIELD*. Enter a numeric value.**

Explanation

The specified string was entered as a value for a parameter that supports only numeric values.

This error can occur after the **svctask chsystemethernet** command is run, if Ethernet traffic priority values are specified that are not integers in the range 0 - 7.

User response

Specify a numeric value in the numeric field, and resubmit the command.

CMMVC5717E **No match was found for the specified unit.**

Explanation

Certain parameters allow a user to specify a data unit such as mb or kb. You have entered a data unit for a parameter that supports data units, but the data unit that you have entered is not a supported data unit for the parameter.

User response

Specify the correct data unit, and resubmit the command.

CMMVC5718E **An unexpected return code was received.**

Explanation

The command has completed, but the acknowledgement of the command completion contains a return code that is not defined.

User response

Determine whether or not the command has succeeded. If the command has not succeeded, resubmit the command. If the problem persists, contact IBM technical support for assistance.

CMMVC5719E A value of *VALUE* requires the parameter *PARAMETER* to be specified.

Explanation

Certain commands have required combinations of parameters based on either the entry of a parameter or the value for a parameter. When you enter the specified value, you must enter the specified parameter.

User response

Specify the required parameter, and resubmit the command.

CMMVC5721E *VALUE* is not a valid time stamp format. The valid time stamp format is YYMMDDHHMMSS.

Explanation

The specified value is not a valid time stamp format. The valid format is YYMMDDHHMMSS.

User response

Use the correct time stamp format, and resubmit the command.

CMMVC5722E *VALUE* contains a month value that is not valid. The valid time stamp format is YYMMDDHHMMSS.

Explanation

The month value (MM) that you have specified is not valid.

User response

Specify a valid month value, and resubmit the command.

CMMVC5723E *VALUE* contains a day value that is not valid. The valid time stamp format is YYMMDDHHMMSS.

Explanation

The day value (DD) that you have specified is not valid.

User response

Specify a valid day value, and resubmit the command.

CMMVC5724E *VALUE* contains an hour value that is not valid. The valid time stamp format is YYMMDDHHMMSS.

Explanation

The hour value (HH) that you have specified is not valid.

User response

Specify a valid hour value, and resubmit the command.

CMMVC5725E *VALUE* contains a minutes value that is not valid. The valid time stamp format is YYMMDDHHMMSS.

Explanation

The minutes value (MM) that you have specified is not valid.

User response

Specify a valid minutes value, and resubmit the command.

CMMVC5726E *VALUE* contains a seconds value that is not valid. The valid time stamp format is YYMMDDHHMMSS.

Explanation

The seconds value (SS) that you have specified is not valid.

User response

Specify a valid seconds value, and resubmit the command.

CMMVC5727E *VALUE* is not a valid filter.

Explanation

You can filter the output of some views by using the -filtervalue parameter. The specified string that you have entered is not a supported value for the -filtervalue parameter in this view.

User response

Ensure that you use a supported value for the -filtervalue parameter, and resubmit the command.

CMMVC5728E %1 is not a valid time format. The valid time format is MMDDHHmmYYYY with YYYY<2070.

Explanation

The specified value should be in the format MMDDHHmmYYYY with YYYY less than 2070.

User response

Follow the correct format, and resubmit the command.

CMMVC5729E One or more components in the list is not valid.

Explanation

Certain parameters support one or more items of data in a colon separated list. At least one of the items in the list that you have entered is not correct.

User response

Ensure that you enter supported values in the list, and resubmit the command.

CMMVC5730E VALUE is only valid when VALUE has a value of VALUE .

Explanation

The specified command and parameter combination that you have entered requires the specified parameter value.

User response

Ensure that you specify the correct parameter value for the command and parameter combination that you enter, and resubmit the command.

CMMVC5731E VALUE can only be entered when VALUE has been entered.

Explanation

Certain commands have required combinations of parameters based either on the inclusion of a specified parameter, or on the value entered for a specified parameter. When you include the first specified string in the command, you must enter the second specified string as a parameter.

User response

Ensure that you enter a supported combination or parameters and values, and resubmit the command.

CMMVC5732E The command cannot be initiated because it was not run on the configuration node.

Explanation

The command that you have specified must be run on the configuration node.

User response

Log off of the node service IP address, log on to the management IP address, and run the command on the configuration node.

CMMVC5733E Enter at least one parameter.

Explanation

You must specify at least one parameter for the command that you have submitted.

User response

Specify at least one parameter, and resubmit the command.

CMMVC5734E A combination of values was entered that is not valid.

Explanation

You have specified a combination of values that is not correct.

User response

Specify a supported combination of values, and resubmit the command.

CMMVC5735E The name entered is not valid. Enter an alphanumeric string that does not start with a number.

Explanation

The first character of an object name cannot be numeric.

User response

Specify an alphanumeric string that does not start with a numeric, and resubmit the command.

CMMVC5737E The parameter PARAMETER has been entered multiple times. Enter the parameter only one time.

Explanation

The specified parameter was entered more than once.

User response

Delete all duplicate parameters, and resubmit the command.

CMMVC5738E The argument ARGUMENT contains too many characters.

Explanation

The field length of the specified argument is longer than the maximum supported field length for the argument.

User response

Specify the correct argument, and resubmit the command.

CMMVC5739E The argument *ARGUMENT* does not contain enough characters.

Explanation

The field length of the specified argument is less than the minimum supported field length for the argument.

User response

Specify the correct argument, and resubmit the command.

CMMVC5740E The filter flag *VALUE* is not valid.

Explanation

You can filter the output of some views by using the -filtervalue parameter. The specified string that you have entered is not a supported value for the -filtervalue parameter in this view.

User response

Ensure that you use a supported value for the -filtervalue parameter, and resubmit the command.

CMMVC5741E The filter value *VALUE* is not valid.

Explanation

You can filter the output of some views by using the -filtervalue parameter. Each filter has an associated value. The syntax is -filtervalue filter=value. The specified string that you have entered is not a supported value for the -filtervalue filter that you specified in this view.

User response

Ensure that you use a supported value for the -filtervalue filter that you specify, and resubmit the command.

CMMVC5742E A specified parameter is out of its valid range.

Explanation

You have entered data that is not in the range of values that is supported for the parameter that you have entered.

User response

Ensure that you enter data values that are supported for the parameter that you enter, and resubmit the command.

CMMVC5743E A specified parameter does not comply with the step value.

Explanation

A parameter was specified that does not comply with the step value.

User response

Specify the correct parameter, and resubmit the command.

CMMVC5744E Too many objects were specified in the command.

Explanation

There were too many objects specified in the command.

User response

Specify the correct object, and resubmit the command.

CMMVC5745E Too few objects were specified in the request.

Explanation

There were not enough objects specified in the command.

User response

Specify the correct object, and resubmit the command.

CMMVC5746E The requested operation cannot be applied to the object specified.

Explanation

The requested operation is not valid for this object.

User response

Specify a valid operation, and resubmit the command.

CMMVC5747E The action requested is invalid - internal error.

Explanation

The operation that was requested is not valid.

User response

Specify the correct operation, and resubmit the command.

CMMVC5748E The action requested is invalid - internal error.

Explanation

The operation that was requested is not valid.

User response

Specify the correct operation, and resubmit the command.

CMMVC5749E The dump filename specified already exists.

Explanation

The dump file name that was specified already exists.

User response

Specify a different dump file name, and resubmit the command.

CMMVC5750E The dump file could not be created - the file system is probably full.

Explanation

The dump file was not created. The file system might be full.

User response

Reduce the size of the file system by deleting obsolete logs or other unnecessary files, then retry the command.

CMMVC5751E The dump file could not be written to.

Explanation

The dump file could not be written to disk.

User response

Not applicable.

CMMVC5752E Request failed. The object contains child objects, these must be deleted first.

Explanation

The operation failed because the specified object contains child objects.

User response

Delete the child objects, and resubmit the command.

CMMVC5753E The specified object does not exist or is not a suitable candidate.

Explanation

The specified object does not exist or is not a suitable candidate.

User response

Specify the correct object, and resubmit the command.

CMMVC5754E The specified object does not exist, or the name supplied does not meet the naming rules.

Explanation

The specified object does not exist, or the name of the object does not meet the naming requirements.

User response

Specify the correct object name, and resubmit the command.

CMMVC5755E Cannot create as the sizes of the specified objects do not match.

Explanation

The sizes of the specified objects do not match.

User response

Not applicable.

CMMVC5756E Cannot perform the request as the object id is already mapped to another object or is the subject of an FC or RC relationship.

Explanation

The operation failed because the specified object is already mapped.

User response

Specify a different object, and resubmit the command.

CMMVC5757E Self Defining Structure (SDS) defaults not found - internal error.

Explanation

The defaults for the self describing structure were not found.

User response

Not applicable.

CMMVC5758E Object name already exists.

Explanation

The object name already exists.

User response

Specify a unique object name, and resubmit the command.

CMMVC5759E An internal error has occurred - memory could not be allocated.

Explanation

The memory cannot be allocated.

User response

Not applicable.

CMMVC5762E The request did not complete before the timeout period expired.

Explanation

The operation failed because the timeout period expired.

User response

Resubmit the command.

CMMVC5763E The node failed to go online.

Explanation

The node failed to go online.

User response

Not applicable.

CMMVC5764E The mode change request is invalid - internal error

Explanation

The specified mode change is not valid.

User response

Specify a different mode, and resubmit the command.

CMMVC5765E The object specified is no longer a candidate - a change occurred during the request.

Explanation

The specified object is no longer a candidate. A change occurred during the request.

User response

Specify a different object, and resubmit the command.

CMMVC5767E One or more of the parameters specified are invalid or a parameter is missing.

Explanation

One or more of the specified parameters is not valid.

User response

Specify the correct parameter, and resubmit the command.

CMMVC5769E The requested operation requires all nodes to be online - one or more nodes are not online.

Explanation

The operation requires that all nodes be online. One or more nodes are not online.

User response

Check that each node is online, and resubmit the command.

CMMVC5770E The SSH key file supplied is invalid.

Explanation

The file for the SSH key is not valid.

User response

Specify a different file, and resubmit the command.

CMMVC5771E The operation requested could not complete, usually due to child

objects existing. To force the operation, specify the force flag.

Explanation

The operation failed, probably, because the object contains child objects.

User response

Specify the -force flag to complete the operation, and resubmit the command.

CMMVC5772E The operation requested could not be performed because an update is in progress.

Explanation

The operation failed because an update is in progress.

User response

Wait for the update to complete, and resubmit the command.

CMMVC5773E The object selected is in the wrong mode to perform the requested operation.

Explanation

The operation failed because the selected object is in the wrong mode.

User response

Specify the correct mode, and resubmit the command.

CMMVC5774E The userid supplied is not valid.

Explanation

The userid is not valid.

User response

Specify a different userid, and resubmit the command.

CMMVC5775E The directory attribute specified is not valid.

Explanation

The directory attribute is not valid.

User response

Specify a different directory, and resubmit the command.

CMMVC5776E The directory listing could not be retrieved.

Explanation

The directory listing could not be retrieved.

User response

Specify a different directory listing, and resubmit the command.

CMMVC5777E The node could not be added to the IO Group, because the other node in the IO Group is in the same power domain.

Explanation

The node was not added to the I/O group because the other node in the I/O Group is in the same power domain.

User response

Specify a different node from another I/O group, and resubmit the command.

CMMVC5778E Cannot create another cluster, a cluster already exists.

Explanation

The cluster was not created because one already exists.

User response

Not applicable.

CMMVC5780E The action could not be completed using the Remote Cluster name. Use the Remote Cluster Unique ID instead.

Explanation

The unique ID of the remote cluster is required for this command.

User response

Specify the unique ID of the remote cluster, and resubmit the command.

CMMVC5810E The action failed because the specified resource was unavailable.

Explanation

The resource specified in the action was not available for use.

User response

Fix any errors associated with the specified resource, or reissue the command using an alternative resource.

CMMVC5781E The cluster ID specified is invalid.

Explanation

The cluster ID is not valid.

User response

Specify a different cluster ID, and resubmit the command.

CMMVC5782E The object specified is offline.

Explanation

The object is offline.

User response

Specify an object that is online, and resubmit the command.

CMMVC5783E The information is not available to complete this command.

Explanation

This error is only returned when the node is in the service state.

User response

None.

CMMVC5784E The cluster name specified is not unique, specify the cluster using the cluster ID.

Explanation

The cluster name is not unique.

User response

Specify the cluster using the cluster ID, and resubmit the command.

CMMVC5785E The filename specified contains an illegal character.

Explanation

The filename contains an illegal character.

1886 Spectrum Virtualize for SAN Volume Controller, FlashSystem, and Storwize Family: Command-Line Interface User's Guide

User response

Specify a valid filename, and resubmit the command.

CMMVC5786E The action failed because the cluster is not in a stable state.

Explanation

The action failed because the cluster is not in a stable state.

User response

Not applicable.

CMMVC5787E The cluster was not created because a cluster already exists.

Explanation

The cluster was not created because a cluster already exists.

User response

Not applicable.

CMMVC5788E The service IP address is not valid.

Explanation

The service IP address is not valid.

User response

Specify the correct service IP address, and resubmit the command.

CMMVC5789E The cluster was not modified because the IP address, subnet mask, service address, SNMP address, or gateway address is not valid.

Explanation

The cluster was not modified because the IP address, subnet mask, service address, SNMP address, or gateway address is not valid.

User response

Specify all correct attributes, and resubmit the command.

CMMVC5790E The node was not added to the cluster because the maximum number of nodes has been reached.

Explanation

The node was not added to the cluster because the maximum number of nodes has been reached.

User response

Not applicable.

CMMVC5791E The action failed because an object that was specified in the command does not exist.

Explanation

An entity that was specified in the command does not exist, therefore the action failed.

User response

Specify the correct entity, and resubmit the command.

CMMVC5792E The action failed because the I/O group is used for recovery.

Explanation

The recovery group does not support the command line interface.

User response

Use the management GUI or the **lsiogrp** command to see the list of active I/O groups. Rerun the command with a valid I/O group ID or name.

CMMVC5793E The node was not added to the cluster because the I/O group already contains a pair of nodes.

Explanation

The node was not added to the cluster because the I/O group already contains a pair of nodes.

User response

Not applicable.

CMMVC5794E The action failed because the node is not a member of the cluster.

Explanation

The node is not a member of the cluster, therefore the action failed.

User response

Specify a node that is contained in the cluster, and resubmit the command.

CMMVC5795E The node was not deleted because an update is in progress.

Explanation

The node was not deleted because an update is in progress.

User response

Wait for the update to complete, and resubmit the command.

CMMVC5796E The action failed because the I/O group that the node belongs to is unstable.

Explanation

A previous configuration command might not yet have completed.

User response

Wait for the previous command to complete, and resubmit the command.

CMMVC5797E The node was not deleted because this is the last node in the I/O group and there are virtual disks (VDisks) associated with the I/O group.

Explanation

The specified node is the last node in the I/O group and there are volumes associated with the I/O group, therefore the node could not be deleted.

User response

Not applicable.

CMMVC5798E The action failed because the node is offline.

Explanation

The action failed because the node is offline.

User response

Specify a node that is online, and resubmit the command.

CMMVC5799E The shut down was not successful because there is only one online node in the I/O group.

Explanation

There is only one online node in the I/O group, therefore the shut down operation was not successful.

User response

Not applicable.

CMMVC5800E	The action failed because an entity that was specified in the command does not exist.
-------------------	--

Explanation

The entity that was specified in the command does not exist, therefore the action failed.

User response

Specify a different entity, and resubmit the command.

CMMVC5801E	The update of the cluster could not proceed because every node in the cluster must be online. Either delete the node that is offline or bring the node online and resubmit the command
-------------------	---

Explanation

The update of the cluster could not proceed because every node in the cluster must be online.

User response

Either delete the node that is offline or bring the node online, and resubmit the command.

CMMVC5802E	The update of the cluster could not proceed because there is an I/O group in the cluster that contains only one node. The update requires that each node in an I/O group be shut down and restarted. If there is only one node in an I/O group, I/O operations could be lost if I/O operations are not stopped before beginning the update.
-------------------	--

Explanation

The update of the cluster could not proceed because there is an I/O group in the cluster that contains only one node. The update requires that each node in an I/O group be shut down and restarted. If there is only one node in an I/O group, I/O operations could be lost if I/O operations are not stopped before beginning the update.

User response

Either update the cluster using the -force option or specify a different node, and resubmit the command.

CMMVC5803E	The entry in the error log was not marked because the error is already fixed or unfixed, or the sequence number could not be found.
-------------------	--

Explanation

The entry in the event log was not marked because the sequence number was not found.

User response

Not applicable.

CMMVC5804E	The action failed because an object that was specified in the command does not exist.
-------------------	--

Explanation

The entity that was specified in the command does not exist, therefore the action failed.

User response

Specify a different entity, and resubmit the command.

CMMVC5805E	The progress information was not returned because the FlashCopy statistics are not ready yet.
-------------------	--

Explanation

The progress information was not returned because the FlashCopy statistics are not ready yet.

User response

Not applicable.

CMMVC5806E	The action failed because an object that was specified in the command does not exist.
-------------------	--

Explanation

The entity that was specified in the command does not exist, therefore the action failed.

User response

Specify a different entity, and resubmit the command.

CMMVC5807E	The action failed because the managed disk (MDisk) cannot be changed to the specified mode.
-------------------	--

Explanation

The action failed because the managed disk (MDisk) cannot be changed to the specified mode.

User response

Not applicable.

CMMVC5808E The action failed because the managed disk (MDisk) does not exist.

Explanation

The action failed because the managed disk (MDisk) does not exist.

User response

Specify a different MDisk, and resubmit the command.

CMMVC5809E The tracing of I/O operations was not started because it is already in progress.

Explanation

The tracing of I/O operations was not started because it is already in progress.

User response

Not applicable.

CMMVC5810E The action failed because the specified resource was unavailable.

Explanation

The resource specified in the action was not available for use.

User response

Fix any errors associated with the specified resource, or reissue the command using an alternative resource.

CMMVC5811E The quorum index number for the object was not set because the quorum disk does not exist.

Explanation

An existing quorum disk must be specified before the quorum index number of the object can be set.

User response

Specify an existing quorum disk, and resubmit the command.

CMMVC5812E The action failed because the managed disk (MDisk) is not in managed mode.

Explanation

The action is only permitted on MDisks that are currently in the managed mode.

User response

Either add the MDisk to a storage pool, or specify a different MDisk.

CMMVC5813E The quorum index number for the object was not set because the object has a sector size that is not valid.

Explanation

The sector size of the specified object will not allow the quorum index number for the object to be set.

User response

Change the sector size of the specified object, or specify a different object, and resubmit the command.

CMMVC5814E The quorum index number for the managed disk (MDisk) was not set because quorum is not allowed on one or more associated controllers.

Explanation

The quorum index number for the managed disk (MDisk) was not set because quorum is not allowed on one or more associated controllers.

User response

Specify an MDisk that has quorum enabled on all of its associated controllers, and resubmit the command.

CMMVC5815E The managed disk group was not created because an entity that was specified in the command does not exist.

Explanation

The storage pool was not created because an entity that was specified in the command does not exist.

User response

Specify a different entity, and resubmit the command.

CMMVC5816E **The action failed because an entity that was specified in the command does not exist.**

Explanation

The action failed because an entity that was specified in the command does not exist.

User response

Specify a different entity, and resubmit the command.

CMMVC5817E **The specified managed disk group was invalid.**

Explanation

The storage pool was not renamed because the name was not valid.

User response

Specify a different storage pool name, and resubmit the command.

CMMVC5818E **The managed disk group was not deleted because there is at least one MDisk in the group.**

Explanation

The storage pool was not deleted because there is at least one MDisk in the group.

User response

Not applicable.

CMMVC5819E **The managed disk (MDisk) was not added to the MDisk group because the MDisk is part of another MDisk group.**

Explanation

The managed disk (MDisk) was not added to the storage pool because the MDisk is part of another storage pool.

User response

Not applicable.

CMMVC5820E **The managed disk (MDisk) was not added to the MDisk group because an entity that was specified in the command does not exist.**

Explanation

The managed disk (MDisk) was not added to the storage pool because an entity that was specified in the command does not exist.

User response

Specify a different entity, and resubmit the command.

CMMVC5821E **The managed disk (MDisk) was not added to the MDisk group because not enough MDisk were included in the list.**

Explanation

The managed disk (MDisk) was not added to the storage pool because not enough MDisk were included in the list.

User response

Include more MDisk in the list, and resubmit the command.

CMMVC5822E **The managed disk (MDisk) was not added to the MDisk group because too many MDisk were included in the list.**

Explanation

The managed disk (MDisk) was not added to the storage pool because too many MDisk were included in the list.

User response

Delete the extra MDisk in the list, and resubmit the command.

CMMVC5823E **The managed disk (MDisk) was not deleted from the MDisk group because the MDisk is part of another MDisk group.**

Explanation

The managed disk (MDisk) was not deleted from the storage pool because the MDisk is part of another storage pool.

User response

Not applicable.

CMMVC5824E **The managed disk (MDisk) was not deleted from the MDisk group because it does not belong to the MDisk group.**

Explanation

The managed disk (MDisk) was not deleted from the storage pool because it does not belong to the storage pool.

User response

Not applicable.

CMMVC5825E **The managed disk (MDisk) was not deleted from the MDisk group because a virtual disk (VDisk) is allocated from one or more of the specified MDisks. A forced deletion is required.**

Explanation

The managed disk (MDisk) was not deleted from the storage pool because a volume is allocated from one or more of the specified MDisks.

User response

Specify the -force option, and resubmit the command.

CMMVC5826E **The virtual disk (VDisk) was not created because an entity that was specified in the command does not exist.**

Explanation

The volume was not created because an entity that was specified in the command does not exist.

User response

Specify a different entity, and resubmit the command.

CMMVC5827E **The command failed as a result of either an inconsistency between two or more of the entered parameters, or an inconsistency between a parameter and the requested action.**

Explanation

The command failed as a result of an inconsistency between two or more of the entered parameters.

User response

Specify one parameter, and resubmit the command.

CMMVC5828E **The virtual disk (VDisk) was not created because the I/O group contains no nodes.**

Explanation

The volume was not created because the I/O group contains no nodes.

User response

Not applicable.

CMMVC5829E **The image-mode or sequential-mode virtual disk (VDisk) was not created because more than one managed disk (MDisk) is specified.**

Explanation

The image-mode or sequential-mode volume was not created because more than one MDisk is specified.

User response

Specify a different MDisk, and resubmit the command.

CMMVC5830E **The image-mode virtual disk (VDisk) was not created because no managed disk (MDisk) was specified in the command.**

Explanation

The image-mode volume was not created because no managed disk (MDisk) was specified in the command.

User response

Specify a MDisk, and resubmit the command.

CMMVC5831E **The virtual disk (VDisk) was not created because the preferred node for I/O operations is not part of the I/O group.**

Explanation

The volume was not created because the preferred node for I/O operations is not part of the I/O group.

User response

Specify a different node, and resubmit the command.

CMMVC5832E **The property of the virtual disk (VDisk) was not modified because an entity that was specified in the command does not exist.**

Explanation

The property of the volume was not modified because an entity that was specified in the command does not exist.

User response

Specify a different entity, and resubmit the command.

CMMVC5833E **The property of the virtual disk (VDisk) was not modified because there are no nodes in the I/O group.**

Explanation

The property of the volume was not modified because there are no nodes in the I/O group.

User response

Not applicable.

CMMVC5834E **The I/O group for the virtual disk (VDisk) was not modified because the group is a recovery I/O group. To modify the I/O group, use the force option.**

Explanation

The I/O group for the volume was not modified because the group is a recovery I/O group.

User response

Specify the -force option, and resubmit the command.

CMMVC5835E **The virtual disk (VDisk) was not expanded because an entity that was specified in the command does not exist.**

Explanation

The volume was not expanded because an entity that was specified in the command does not exist.

User response

Specify a different entity, and resubmit the command.

CMMVC5836E **The virtual disk (VDisk) was not shrunk because it is locked.**

Explanation

Commands might still be running in the background.

User response

Wait for all commands to complete. Use the lsmigrate command to view any migrates running in the background.

CMMVC5837E **The action failed because the virtual disk (VDisk) is part of a FlashCopy mapping.**

Explanation

The action failed because the volume is part of a FlashCopy mapping.

User response

Specify a different volume that is not part of a FlashCopy mapping, and resubmit the command.

CMMVC5838E **The action failed because the virtual disk (VDisk) is part of a Remote Copy mapping.**

Explanation

The action failed because the volume is part of a Remote Copy mapping.

User response

Specify a different volume that is not part of a Remote Copy mapping, and resubmit the command.

CMMVC5839E **The virtual disk (VDisk) was not shrunk because an object that was specified in the command does not exist.**

Explanation

The volume was not shrunk because an object that was specified in the command does not exist.

User response

Specify a different object, and resubmit the command.

CMMVC5840E **The volume was not deleted because it is mapped to a host, or it is part of a FlashCopy mapping or Remote Copy relationship, or a cloud snapshot or restore operation is in progress, or it is involved in an image mode migration.**

Explanation

The volume was not deleted for one of the following reasons:

- It is mapped to a host
- It is part of a FlashCopy mapping
- It is in a remote copy relationship
- A cloud snapshot operation is in progress

- A restore operation is in progress

User response

Make sure that you specified the correct volume. If so, take one or more of the following actions:

- If the volume is mapped to a host, remove the host mapping.
- If the volume is part of a FlashCopy mapping, remove the mapping.
- If the volume is in a remote copy relationship, remove it from the relationship.
- If a cloud snapshot or restore operation is in progress, either wait for the operation to finish or cancel the operation.

When the volume is available for deletion, retry the delete command.

CMMVC5841E The virtual disk (VDisk) was not deleted because it does not exist.

Explanation

The volume was not deleted because it does not exist.

User response

Specify a different volume, and resubmit the command.

CMMVC5842E The action failed because an object that was specified in the command does not exist.

Explanation

The action failed because an entity that was specified in the command does not exist.

User response

Specify a different entity, and resubmit the command.

CMMVC5843E The VDisk-to-host mapping was not created because the VDisk does not have a capacity greater than zero bytes.

Explanation

The host map was not created because the volume does not have a capacity greater than zero bytes.

User response

Specify a volume in which its capacity is greater than zero bytes, and resubmit the command.

CMMVC5844E The VDisk-to-host mapping was not created because the SCSI logical unit number (LUN) ID is not valid.

Explanation

The host map was not created because the SCSI logical unit number (LUN) ID is not valid.

User response

Specify the correct SCSI logical unit number (LUN) ID, and resubmit the command.

CMMVC5845E The extent was not migrated because an object that was specified in the command does not exist.

Explanation

The extent was not migrated because an object that was specified in the command does not exist.

User response

Specify a different object, and resubmit the command.

CMMVC5846E The virtual disk (VDisk) was not migrated because an object that was specified in the command does not exist.

Explanation

The volume was not migrated because an object that was specified in the command does not exist.

User response

Specify a different object, and resubmit the command.

CMMVC5847E The virtual disk (VDisk) was not migrated because its associated managed disk (MDisk) is already in the MDisk group.

Explanation

The volume was not migrated because its associated managed disk (MDisk) is already in the storage pool.

User response

Not applicable.

CMMVC5848E The action failed because the virtual disk (VDisk) does not exist or it is being deleted.

Explanation

The action failed because the volume does not exist or it is being deleted.

User response

Specify a different volume, and resubmit the command.

CMMVC5849E The migration failed because some or all of the extents are already being migrated.

Explanation

The migration failed because some or all of the extents are already being migrated.

User response

Not applicable.

CMMVC5850E The extent was not migrated because there is a problem with the source extents.

Explanation

The extent was not migrated because there is a problem with the source extents.

User response

Not applicable.

CMMVC5851E The extent was not migrated because there is a problem with the target extents.

Explanation

The extent was not migrated because there is a problem with the target extents.

User response

Not applicable.

CMMVC5852E The migration failed because there are too many migrations in progress.

Explanation

The migration failed because there are too many migrations in progress.

User response

Wait for the migration process to complete, and resubmit the command.

CMMVC5853E The action failed because there was a problem with the group.

Explanation

An attempt was made to work on a volume which is using a storage pool with one of the following problems:

- The target and source storage pools have different extent sizes (group migrate).
- The target and source storage pools are the same (group migrate).
- The target and source storage pools are different (extents migrate).
- The target group (group migrate) is not valid.
- The source group (group migrate) is not valid.

User response

Ensure that none of the above conditions exist before reissuing the command.

CMMVC5854E The extent information was not returned because the extent is not used or does not exist.

Explanation

The extent information was not returned because the extent is not used or does not exist.

User response

Specify the correct extent, and resubmit the command.

CMMVC5855E The extent information was not returned because the managed disk (MDisk) is not used by any virtual disk (VDisk).

Explanation

The extent information was not returned because the managed disk (MDisk) is not used by any volume.

User response

Specify the correct MDisk, and resubmit the command.

CMMVC5856E The action failed because the virtual disk (VDisk) does not belong to the specified managed disk group.

Explanation

The action failed because the volume does not belong to the specified storage pool.

User response

Specify a different volume, and resubmit the command.

CMMVC5857E **The action failed because the managed disk (MDisk) does not exist or it is not a member of the managed disk group.**

Explanation

The action failed because the managed disk (MDisk) does not exist or it is not a member of the storage pool.

User response

Specify a different MDisk, and resubmit the command.

CMMVC5858E **The action failed because the virtual disk (VDisk) is in the wrong mode, the managed disk (MDisk) is in the wrong mode, or both are in the wrong mode.**

Explanation

The action failed because the volume is in the wrong mode, the managed disk (MDisk) is in the wrong mode, or both are in the wrong mode.

User response

Check that the volume and MDisk are in the correct mode, and resubmit the command.

CMMVC5859E **The migration did not complete because an error occurred during the migration of the last extent on an image-mode virtual disk (VDisk).**

Explanation

The migration did not complete because an error occurred during the migration of the last extent on an image-mode volume.

User response

Not applicable.

CMMVC5860E **The action failed because there were not enough extents in the managed disk group.**

Explanation

This error is also returned if a stripe set of MDisks has been specified and one or more of these MDisks does

not contain enough free extents to complete the creation of the volume.

User response

In this case, the storage pool reports that it has enough free capacity to create the volume. You can check the free capacity on each MDisk by submitting the command `lsfreeextents <mdiskname/ID>`. Alternatively, do not specify a stripe set and let the system choose the free extents automatically.

CMMVC5861E **The action failed because there were not enough extents on the managed disk (MDisk).**

Explanation

The action failed because there were not enough extents on the managed disk (MDisk).

User response

Specify another extent, and resubmit the command.

CMMVC5862E **The action failed because the virtual disk (VDisk) is being formatted.**

Explanation

The action failed because the volume is being formatted.

User response

Wait for the volume to be successfully formatted, and resubmit the command.

CMMVC5863E **The migration failed because there are not enough free extents on the target managed disk (MDisk).**

Explanation

The migration failed because there are not enough free extents on the target managed disk (MDisk).

User response

Specify another free extent, and resubmit the command.

CMMVC5864E **The extent information was not returned because the source extent is not used.**

Explanation

The extent information was not returned because the source extent is not used.

User response

Specify a different source extent, and resubmit the command.

CMMVC5865E **The action failed because the extent is out of range for the managed disk (MDisk) or virtual disk (VDisk) specified.**

Explanation

The extent information was not returned because the extent is out of range for the managed disk (MDisk) or volume.

User response

Specify a different extent which is in range for the MDisk or volume and resubmit the command.

CMMVC5866E **The action failed because the extent contains internal data.**

Explanation

The extent was not migrated because the extent contains internal data.

User response

Not applicable.

CMMVC5867E **The action failed because the worldwide port name is already assigned or is not valid.**

Explanation

The action failed because the worldwide port name is already assigned or is not valid.

User response

Specify a different worldwide port name, and resubmit the command.

CMMVC5868E **The action failed because an entity that was specified in the command does not exist.**

Explanation

The action failed because an entity that was specified in the command does not exist.

User response

Specify a different entity, and resubmit the command.

CMMVC5869E **The host object was not renamed because the host ID or name is not valid.**

Explanation

The host object was not renamed because the host ID or name is not valid.

User response

Specify a different host ID or name, and resubmit the command.

CMMVC5870E **The host object was not deleted because an entity that was specified in the command does not exist.**

Explanation

The host object was not deleted because an entity that was specified in the command does not exist.

User response

Specify the correct entity, and resubmit the command.

CMMVC5871E **The host object was not deleted because it is mapped to one or more volumes.**

Explanation

There is at least one volume mapped to this host. Therefore the host object cannot be deleted without the loss of data.

User response

Verify that you are attempting to delete the correct host. If so, use the **lshostvdiskmap** command to locate the volumes that are mapped to this host.

If you are sure that these mappings are no longer required, remove them using the **rmvdiskhostmap** command, and retry the original **rmhost** command.

CMMVC5872E **The port (WWPN) was not added to the host object because an object that was specified in the command does not exist.**

Explanation

The port (WWPN) was not added to the host object because an object that was specified in the command does not exist.

User response

Specify the correct object, and resubmit the command.

CMMVC5873E **No matching WWPN.**

Explanation

The action failed because there is no matching worldwide port name.

User response

Not applicable.

CMMVC5874E **The action failed because the host does not exist.**

Explanation

The action failed because the host does not exist.

User response

Specify a different host, and resubmit the command.

CMMVC5875E **The action failed because the virtual disk (VDisk) does not exist.**

Explanation

The action failed because the volume does not exist.

User response

Specify a different volume, and resubmit the command.

CMMVC5876E **The VDisk-to-host mapping was not created because the maximum number of mappings has been reached.**

Explanation

The host map was not created because the maximum number of mappings has been reached.

User response

Not applicable.

CMMVC5877E **The VDisk-to-host mapping was not created because the maximum number of SCSI LUNs has been allocated.**

Explanation

The host map was not created because the maximum number of SCSI LUNs has been allocated.

User response

Not applicable.

CMMVC5878E **The VDisk-to-host mapping was not created because this VDisk is already mapped to this host.**

Explanation

The host map was not created because this volume is already mapped to this host.

User response

Specify a different volume, and resubmit the command.

CMMVC5879E **The VDisk-to-host mapping was not created because a VDisk is already mapped to this host with this SCSI LUN.**

Explanation

The host map was not created because this SCSI LUN is already assigned to another mapping.

User response

Specify a different SCSI LUN, and resubmit the command.

CMMVC5880E **The virtual disk was not created because a capacity of zero bytes is not allowed for image mode disks.**

Explanation

The host map was not created because the volume has a capacity of zero bytes.

User response

Specify a different volume, and resubmit the command.

CMMVC5881E **The FlashCopy mapping was not created because an entity that was specified in the command does not exist.**

Explanation

The FlashCopy mapping was not created because an entity that was specified in the command does not exist.

User response

Specify a different entity, and resubmit the command.

CMMVC5882E **The FlashCopy mapping was not created because a mapping for the source or target virtual disk (VDisk) already exists.**

Explanation

The FlashCopy mapping was not created because a mapping for the source or target volume already exists.

User response

Specify a different source or target volume, and resubmit the command.

CMMVC5883E **The FlashCopy mapping was not created because the recovery I/O group is associated with the source or target virtual disk (VDisk).**

Explanation

The FlashCopy mapping was not created because the recovery I/O group is associated with the source or target volume.

User response

Specify a different recovery I/O group, and resubmit the command.

CMMVC5884E **The FlashCopy mapping was not created because the source or target virtual disk (VDisk) cannot be a member of a Remote Copy mapping.**

Explanation

The FlashCopy mapping was not created because the source or target volume cannot be a member of a Remote Copy mapping.

User response

Specify a different source or target volume, and resubmit the command.

CMMVC5885E **The FlashCopy mapping was not created because this source or target virtual disk (VDisk) cannot be a member of a FlashCopy mapping.**

Explanation

The FlashCopy mapping was not created because this source or target volume cannot be a member of a FlashCopy mapping.

User response

Specify a different source or target volume, and resubmit the command.

CMMVC5886E **The FlashCopy mapping was not created because the source or target virtual disk (VDisk) is associated with the recovery I/O group.**

Explanation

The FlashCopy mapping was not created because the source or target volume is associated with the recovery I/O group.

User response

Specify a different source or target volume, and resubmit the command.

CMMVC5887E **The FlashCopy mapping was not created because the source or target virtual disk (VDisk) must not be in router mode.**

Explanation

The FlashCopy mapping was not created because the source or target volume must not be in router mode.

User response

Specify a different source or target volume, and resubmit the command.

CMMVC5888E **The action failed because an entity that was specified in the command does not exist.**

Explanation

The action failed because an entity that was specified in the command does not exist.

User response

Specify the correct entity, and resubmit the command.

CMMVC5889E **The FlashCopy mapping was not deleted because an entity that was specified in the command does not exist.**

Explanation

The FlashCopy mapping was not deleted because an entity that was specified in the command does not exist.

User response

Specify a different entity, and resubmit the command.

CMMVC5890E	The FlashCopy mapping or consistency group was not started because starting consistency group 0 is not a valid operation.
-------------------	--

Explanation

The FlashCopy mapping or consistency group was not started because starting consistency group 0 is not a valid operation.

User response

Not applicable.

CMMVC5891E	The FlashCopy consistency group was not created because the name is not valid.
-------------------	---

Explanation

The FlashCopy consistency group was not created because the name is not valid.

User response

Specify a different name, and resubmit the command.

CMMVC5892E	The FlashCopy consistency group was not created because it already exists.
-------------------	---

Explanation

The FlashCopy consistency group was not created because it already exists.

User response

Not applicable.

CMMVC5893E	The action failed because an entity that was specified in the command does not exist.
-------------------	--

Explanation

The action failed because an entity that was specified in the command does not exist.

User response

Specify the correct entity, and resubmit the command.

CMMVC5894E	The FlashCopy consistency group was not deleted because you are trying to delete consistency group 0 or the name of the consistency group is not valid.
-------------------	--

Explanation

The FlashCopy consistency group was not deleted because the name of the consistency group is not valid or you are trying to delete consistency group 0.

User response

Specify the correct consistency group, and resubmit the command.

CMMVC5895E	The FlashCopy consistency group was not deleted because it contains mappings. To delete this consistency group, a forced deletion is required.
-------------------	---

Explanation

The FlashCopy consistency group was not deleted because it contains mappings.

User response

Specify that -force option to delete the consistency group.

CMMVC5896E	The FlashCopy mapping was not deleted because the mapping or consistency group is in the preparing state. The mapping or consistency group must be stopped first.
-------------------	--

Explanation

The FlashCopy mapping was not deleted because the mapping or consistency group is in the preparing state. The mapping or consistency group must be stopped first.

User response

Stop the consistency group, and resubmit the command.

CMMVC5897E	The FlashCopy mapping was not deleted because the mapping or consistency group is in the prepared state. The mapping or
-------------------	--

consistency group must be stopped first.

Explanation

The FlashCopy mapping was not deleted because the mapping or consistency group is in the prepared state. The mapping or consistency group must be stopped first.

User response

Stop the consistency group, and resubmit the command.

CMMVC5898E	The FlashCopy mapping was not deleted because the mapping or consistency group is in the copying state. The mapping or consistency group must be stopped first.
-------------------	--

Explanation

The FlashCopy mapping was not deleted because the mapping or consistency group is in the copying state. The mapping or consistency group must be stopped first.

User response

Stop the consistency group, and resubmit the command.

CMMVC5899E	The FlashCopy mapping was not deleted because the mapping or consistency group is in the stopped state. To delete the mapping, a forced deletion is required.
-------------------	--

Explanation

The FlashCopy mapping was not deleted because the mapping or consistency group is in the stopped state.

User response

Specify the -force option to delete the mapping.

CMMVC5900E	The FlashCopy mapping was not deleted because the mapping or consistency group is in the suspended state. The mapping or consistency group must be stopped first.
-------------------	--

Explanation

The FlashCopy mapping was not deleted because the mapping or consistency group is in the suspended

state. The mapping or consistency group must be stopped first.

User response

Stop the consistency group, and resubmit the command.

CMMVC5901E	The FlashCopy mapping was not prepared because the mapping or consistency group is already in the preparing state.
-------------------	---

Explanation

The FlashCopy mapping was not prepared because the mapping or consistency group is already in the preparing state.

User response

Not applicable.

CMMVC5902E	The FlashCopy mapping was not prepared because the mapping or consistency group is already in the prepared state.
-------------------	--

Explanation

The FlashCopy mapping was not prepared because the mapping or consistency group is already in the prepared state.

User response

Not applicable.

CMMVC5903E	The FlashCopy mapping was not prepared because the mapping or consistency group is already in the copying state.
-------------------	---

Explanation

The FlashCopy mapping was not prepared because the mapping or consistency group is already in the copying state.

User response

Not applicable.

CMMVC5904E	The FlashCopy mapping was not prepared because the mapping or consistency group is already in the suspended state.
-------------------	---

Explanation

The FlashCopy mapping was not prepared because the mapping or consistency group is already in the suspended state.

User response

Not applicable.

CMMVC5905E **The FlashCopy mapping or consistency group was not started because the mapping or consistency group is in the idle state. The mapping or consistency group must be prepared first.**

Explanation

The FlashCopy mapping or consistency group was not started because the mapping or consistency group is in the idle state.

User response

Prepare the mapping or consistency group, and resubmit the command.

CMMVC5906E **The FlashCopy mapping or consistency group was not started because the mapping or consistency group is in the preparing state.**

Explanation

The FlashCopy mapping or consistency group was not started because the mapping or consistency group is in the preparing state.

User response

Not applicable.

CMMVC5907E **The FlashCopy mapping or consistency group was not started because the mapping or consistency group is already in the copying state.**

Explanation

The FlashCopy mapping or consistency group was not started because the mapping or consistency group is already in the copying state.

User response

Not applicable.

CMMVC5908E **The FlashCopy mapping or consistency group was not started because the mapping or consistency group is in the stopped state. The mapping or consistency group must be prepared first.**

Explanation

The FlashCopy mapping or consistency group was not started because the mapping or consistency group is in the stopped state.

User response

Prepare the mapping or consistency group, and resubmit the command.

CMMVC5909E **The FlashCopy mapping or consistency group was not started because the mapping or consistency group is in the suspended state.**

Explanation

The FlashCopy mapping or consistency group was not started because the mapping or consistency group is in the suspended state.

User response

Not applicable.

CMMVC5910E **The FlashCopy mapping or consistency group was not stopped because the mapping or consistency group is in the idle state.**

Explanation

The FlashCopy mapping or consistency group was not stopped because the mapping or consistency group is in the idle state.

User response

Not applicable.

CMMVC5911E **The FlashCopy mapping or consistency group was not stopped because the mapping or consistency group is in the preparing state.**

Explanation

The FlashCopy mapping or consistency group was not stopped because the mapping or consistency group is in the preparing state.

User response

Not applicable.

CMMVC5912E **The FlashCopy mapping or consistency group was not stopped because the mapping or consistency group is already in the stopped state.**

Explanation

The FlashCopy mapping or consistency group was not stopped because the mapping or consistency group is already in the stopped state.

User response

Not applicable.

CMMVC5913E **The properties of the FlashCopy mapping were not modified because the mapping or consistency group is in the preparing state.**

Explanation

The properties of the FlashCopy mapping were not modified because the mapping or consistency group is in the preparing state.

User response

Not applicable.

CMMVC5914E **The properties of the FlashCopy mapping were not modified because the mapping or consistency group is in the prepared state.**

Explanation

The properties of the FlashCopy mapping were not modified because the mapping or consistency group is in the prepared state.

User response

Not applicable.

CMMVC5915E **The properties of the FlashCopy mapping were not modified because the mapping or**

consistency group is in the copying state.

Explanation

The properties of the FlashCopy mapping were not modified because the mapping or consistency group is in the copying state.

User response

Not applicable.

CMMVC5916E **The properties of the FlashCopy mapping were not modified because the mapping or consistency group is in the suspended state.**

Explanation

The properties of the FlashCopy mapping were not modified because the mapping or consistency group is in the suspended state.

User response

Not applicable.

CMMVC5917E **The FlashCopy mapping was not created because there is no memory in which to create the bitmap.**

Explanation

The FlashCopy mapping was not created because there is no memory to create the bitmap.

User response

Not applicable.

CMMVC5918E **The FlashCopy mapping was not prepared, either because there are no online nodes in the I/O group or because there are unrecovered FlashCopy mappings or unrecovered Global Mirror or Metro Mirror relationships in the I/O group.**

Explanation

This error might be caused by a temporary loss of all of the nodes in the I/O group, which causes all of the FlashCopy mappings and Global and Metro Mirror relationships of the I/O group to be unusable.

User response

Perform the following steps:

1. Ensure that at least one of the nodes in the I/O group of the mapping is online.
2. Fix all of the unfixed events in the event log.
3. Follow the fix procedures.

You might be required to delete and re-add ALL of the FlashCopy maps and Global and Metro Mirror relationships in the I/O group.

Resubmit the command.

CMMVC5919E **The FlashCopy mapping or consistency group was not started, either because there are no online nodes in the I/O group or because there are unrecovered FlashCopy mappings or unrecovered Global Mirror or Metro Mirror relationships in the I/O group.**

Explanation

This error might be caused by a temporary loss of all of the nodes in the I/O group, which causes all of the FlashCopy mappings and Global and Metro Mirror relationships of the I/O group to be unusable.

User response

Perform the following steps:

1. Ensure that at least one of the nodes in the I/O group of the mapping is online.
2. Fix all of the unfixed events in the event log.
3. Follow the fix procedures.

You might be required to delete and re-add ALL of the FlashCopy maps and Global and Metro Mirror relationships in the I/O group.

Resubmit the command.

CMMVC5920E **The FlashCopy mapping was not created because the consistency group is not idle.**

Explanation

The FlashCopy mapping was not created because the consistency group is not idle.

User response

Not applicable.

CMMVC5921E **The properties of the FlashCopy mapping were not modified**

because the consistency group is not idle.

Explanation

The properties of the FlashCopy mapping were not modified because the consistency group is not idle.

User response

Not applicable.

CMMVC5922E **The FlashCopy mapping was not created because the destination virtual disk (VDisk) is too small.**

Explanation

The FlashCopy mapping was not created because the destination volume is too small.

User response

Specify a different volume, and resubmit the command.

CMMVC5923E **The FlashCopy mapping cannot be created, either because there are no online nodes in the I/O group or because there are unrecovered FlashCopy mappings in the I/O group.**

Explanation

This error might be caused by a temporary loss of all of the nodes in the I/O group, which causes all of the FlashCopy mappings to be unusable.

User response

Perform the following steps:

1. Ensure that at least one of the nodes in the I/O group of the mapping is online.
2. Fix all of the unfixed events in the event log.
3. Follow the fix procedures.

You might be required to delete and re-add ALL of the FlashCopy maps and Global and Metro Mirror relationships in the I/O group.

Resubmit the command.

CMMVC5924E **The FlashCopy mapping was not created because the source and target virtual disks (VDisks) are different sizes.**

Explanation

The FlashCopy mapping was not created because the source and target volumes are different sizes.

User response

Specify a different source and target volume that are the same size, and resubmit the command.

CMMVC5925E The remote cluster partnership was not created because it already exists.

Explanation

The remote cluster partnership was not created because it already exists.

User response

Specify a different remote cluster partnership, and resubmit the command.

CMMVC5926E The remote cluster partnership was not created because there are too many partnerships.

Explanation

The remote cluster partnership was not created because there are too many partnerships.

User response

Not applicable.

CMMVC5927E The action failed because the cluster ID is not valid.

Explanation

The action failed because the cluster ID is not valid.

User response

Specify the correct cluster ID, and resubmit the command.

CMMVC5928E The action failed because the cluster name is a duplicate of another cluster.

Explanation

The action failed because the cluster name is a duplicate of another cluster.

User response

Specify a different cluster name, and resubmit the command.

CMMVC5929E The Remote Copy partnership was not deleted because it has already been deleted.

Explanation

The Remote Copy partnership was not deleted because it has already been deleted.

User response

Not applicable.

CMMVC5930E The Remote Copy relationship was not created because an object that was specified in the command does not exist.

Explanation

The Remote Copy relationship was not created because an object that was specified in the command does not exist.

User response

Specify the correct object, and resubmit the command.

CMMVC5931E The Remote Copy relationship was not created because the master or auxiliary virtual disk (VDisk) is locked.

Explanation

The Remote Copy relationship was not created because the master or auxiliary volume is locked.

User response

Unlock the master or auxiliary volume, and resubmit the command.

CMMVC5932E The Remote Copy relationship was not created because the master or auxiliary virtual disk (VDisk) is a member of a FlashCopy mapping.

Explanation

The Remote Copy relationship was not created because the master or auxiliary volume is a member of a FlashCopy mapping, and the partner cluster is running a downlevel software version.

User response

Not applicable.

CMMVC5933E **The Remote Copy relationship was not created because the master or auxiliary virtual disk (VDisk) is in the recovery I/O group.**

Explanation

The Remote Copy relationship was not created because the master or auxiliary volume is in the recovery I/O group.

User response

Not applicable.

CMMVC5934E **The Remote Copy relationship was not created because the master or auxiliary virtual disk (VDisk) is in the router mode.**

Explanation

The Remote Copy relationship was not created because the master or auxiliary volume is in the router mode.

User response

Not applicable.

CMMVC5935E **The action failed because an object that was specified in the command does not exist.**

Explanation

The action failed because an object that was specified in the command does not exist.

User response

Specify the correct object, and resubmit the command.

CMMVC5936E **The action failed because an object that was specified in the command does not exist.**

Explanation

The action failed because an object that was specified in the command does not exist.

User response

Specify the correct object, and resubmit the command.

CMMVC5937E **The action failed because an object that was specified in the command does not exist.**

Explanation

The action failed because an object that was specified in the command does not exist.

User response

Specify the correct object, and resubmit the command.

CMMVC5938E **The Remote Copy consistency group was not deleted because the consistency group contains relationships. To delete the consistency group, the force option is required.**

Explanation

Remote Copy consistency group was not deleted because the consistency group contains relationships.

User response

Specify the -force option to delete the consistency group.

CMMVC5939E **The action failed because the cluster is not in a stable state.**

Explanation

The action failed because the cluster is not in a stable state.

User response

Not applicable.

CMMVC5940E **The cluster that contains the auxiliary virtual disk (VDisk) is unknown.**

Explanation

The cluster that contains the auxiliary volume is unknown.

User response

Not applicable.

CMMVC5941E **The cluster that contains the master virtual disk (VDisk) has too many consistency groups.**

Explanation

The cluster that contains the master volume has too many consistency groups.

User response

Not applicable.

CMMVC5942E **The cluster that contains the auxiliary virtual disk (VDisk) has too many consistency groups.**

Explanation

The cluster that contains the auxiliary volume has too many consistency groups.

User response

Not applicable.

CMMVC5943E **The specified relationship is not valid.**

Explanation

The specified relationship is not valid.

User response

Specify the correct relationship, and resubmit the command.

CMMVC5944E **The specified consistency group is not valid.**

Explanation

The specified consistency group is not valid.

User response

Specify the correct consistency group, and resubmit the command.

CMMVC5945E **The specified master cluster is not valid.**

Explanation

The specified master cluster is not valid.

User response

Specify the correct master cluster, and resubmit the command.

CMMVC5946E **The specified auxiliary cluster is not valid.**

Explanation

The specified auxiliary cluster is not valid.

User response

Specify the correct auxiliary cluster, and resubmit the command.

CMMVC5947E **The specified master virtual disk (VDisk) is not valid.**

Explanation

The specified master volume is not valid.

User response

Specify the correct master volume, and resubmit the command.

CMMVC5948E **The specified auxiliary virtual disk (VDisk) is not valid.**

Explanation

The specified auxiliary volume is not valid.

User response

Specify the auxiliary volume, and resubmit the command.

CMMVC5949E **The specified relationship is unknown.**

Explanation

The specified relationship is unknown.

User response

Specify a different relationship, and resubmit the command.

CMMVC5950E **The specified consistency group is unknown.**

Explanation

The specified consistency group is unknown.

User response

Specify a different consistency group, and resubmit the command.

CMMVC5951E **The operation cannot be performed because the relationship is not a stand-alone relationship.**

Explanation

The operation cannot be performed because the relationship is not a stand-alone one.

User response

Not applicable.

CMMVC5952E **The relationship and consistency group have different master clusters.**

Explanation

The relationship and consistency group have different master clusters.

User response

Not applicable.

CMMVC5953E **The relationship and group have different auxiliary clusters.**

Explanation

The relationship and group have different auxiliary clusters.

User response

Not applicable.

CMMVC5954E **The master and auxiliary virtual disks (VDisks) are different sizes.**

Explanation

The master and auxiliary volumes are different sizes

User response

Not applicable.

CMMVC5955E **The maximum number of relationships has been reached.**

Explanation

The maximum number of relationships has been reached.

User response

Not applicable.

CMMVC5956E **The maximum number of consistency groups has been reached.**

Explanation

The maximum number of consistency groups has been reached.

User response

Not applicable.

CMMVC5957E **The master virtual disk (VDisk) is already in a relationship.**

Explanation

The master volume is already in a relationship.

User response

Specify a different master volume, and resubmit the command.

CMMVC5958E **The auxiliary virtual disk (VDisk) is already in a relationship.**

Explanation

The auxiliary volume is already in a relationship.

User response

Specify a different auxiliary volume, and resubmit the command.

CMMVC5959E **There is a relationship that already has this name on the master cluster.**

Explanation

There is a relationship that already has this name on the master cluster.

User response

Specify a different name, and resubmit the command.

CMMVC5960E **There is a relationship that already has this name on the auxiliary cluster.**

Explanation

There is a relationship that already has this name on the auxiliary cluster.

User response

Specify a different name, and resubmit the command.

CMMVC5961E **There is a consistency group that already has this name on the master cluster.**

Explanation

There is a consistency group that already has this name on the master cluster.

User response

Specify a different name, and resubmit the command.

CMMVC5962E **There is a consistency group that already has this name on the auxiliary cluster.**

Explanation

There is a consistency group that already has this name on the auxiliary cluster.

User response

Specify a different name, and resubmit the command.

CMMVC5963E **No direction has been defined.**

Explanation

No direction has been defined.

User response

Not applicable.

CMMVC5964E **The copy priority is not valid.**

Explanation

The copy priority is not valid.

User response

Not applicable.

CMMVC5965E **The virtual disks (VDisks) are in different I/O groups on the local cluster.**

Explanation

The volumes are in different I/O groups on the local cluster.

User response

Not applicable.

CMMVC5966E **The master virtual disk (VDisk) is unknown.**

Explanation

The master volume is unknown.

User response

Specify a different master volume, and resubmit the command.

CMMVC5967E **The auxiliary virtual disk (VDisk) is unknown.**

Explanation

The auxiliary volume is unknown.

User response

Specify a different auxiliary volume, and resubmit the command.

CMMVC5968E **The relationship cannot be added because the states of the relationship and the consistency group do not match.**

Explanation

The relationship cannot be added because the states of the relationship and the consistency group do not match.

User response

Not applicable.

CMMVC5969E **The Remote Copy relationship was not created, either because there are no online nodes in the I/O group or because there are unrecovered FlashCopy mappings or unrecovered Global Mirror or Metro Mirror relationships in the I/O group.**

Explanation

This error might be caused by a temporary loss of all of the nodes in the I/O group, which causes all of the FlashCopy mappings and Global and Metro Mirror relationships of the I/O group to be unusable.

User response

Perform the following steps:

1. Ensure that at least one of the nodes in the I/O group is online.
2. Fix all of the unfixed events in the event log.
3. Follow the fix procedures.

You might be required to delete and re-add ALL of the FlashCopy maps and Global and Metro Mirror relationships in the I/O group.

Resubmit the command.

CMMVC5970E **The Remote Copy relationship was not created because there is not enough memory.**

Explanation

The Remote Copy relationship was not created because there is not enough memory.

User response

Increase the memory with the `chiogrp` command.

CMMVC5971E	The operation was not performed because the consistency group contains no relationships.
-------------------	---

Explanation

The operation was not performed because the consistency group contains no relationships.

User response

Not applicable.

CMMVC5972E	The operation was not performed because the consistency group contains relationships.
-------------------	--

Explanation

The operation was not performed because the consistency group contains relationships.

User response

Not applicable.

CMMVC5973E	The operation was not performed because the consistency group is not synchronized.
-------------------	---

Explanation

The operation was not performed because the consistency group is not synchronized.

User response

Specify the Force option when starting the consistency group.

CMMVC5974E	The operation did not complete because one or more volumes in the consistency group are offline or inaccessible.
-------------------	---

Explanation

This error can occur because one or more of the source or target volumes for relationships within the consistency group is offline. The error can also be caused if one or more of the source or target volumes are inaccessible because it is participating in a FlashCopy mapping that is prepared or incomplete.

User response

Complete the following steps:

- Ensure that at least one of the nodes in the I/O group of each of the source and target volumes is online.
- Ensure that the source and target volumes for each relationship in the consistency group are online.
- Correct any problems that might be holding the source or target volumes offline. For example, a thin-provisioned volume might be held offline if all available space is allocated.
- Ensure that any FlashCopy mappings that involve the source or target volumes for each relationship are complete.
- Fix all of the unfixed events that are in the event log.

CMMVC5975E	The operation was not performed because the cluster partnership is not connected.
-------------------	--

Explanation

The operation was not performed because the cluster partnership is not connected.

User response

Not applicable.

CMMVC5976E	The operation was not performed because the consistency group is in the freezing state.
-------------------	--

Explanation

The operation was not performed because the consistency group is in the freezing state.

User response

Not applicable.

CMMVC5977E	The operation was not performed because it is not valid given the current consistency group state.
-------------------	---

Explanation

The operation was not performed because it is not valid given the current consistency group state.

User response

Not applicable.

CMMVC5978E	The operation was not performed because the relationship is consistent but is not synchronized. Restarting the relationship by
-------------------	---

using the -force parameter will make the relationship inconsistent until the background copy has completed.

Explanation

Input transactions have occurred on either the primary or secondary volumes since the ConsistentStopped or Idling state has occurred. Because the relationship is no longer synchronized, the state of the relationship is now Stopped.

The -force parameter of the starttrcrelationship command is required when the relationship is not synchronized because consistency would be lost by starting the copy operation. Submitting the starttrcrelationship command on an unsynchronized relationship without using the -force parameter is not supported.

If a relationship is in the InconsistentStopped, InconsistentCopying or ConsistentSynchronized state, the -force parameter is not required, but is supported.

User response

Consider using the -force parameter of the starttrcrelationship command, if appropriate.

CMMVC5980E	The operation was not performed because the master and auxiliary clusters are not connected.
-------------------	---

Explanation

The operation was not performed because the master and auxiliary clusters are not connected.

User response

Not applicable.

CMMVC5981E	The operation was not performed because the relationship is in the freezing state.
-------------------	---

Explanation

The operation was not performed because the relationship is in the freezing state.

User response

Not applicable.

CMMVC5982E	The operation was not performed because it is not valid given the current relationship state.
-------------------	--

Explanation

The operation was not performed because it is not valid given the current relationship state.

User response

Not applicable.

CMMVC5983E	dump file was not created. This might be due to the file system being full.
-------------------	--

Explanation

dump file was not created. This might be due to the file system being full.

User response

Not applicable.

CMMVC5984E	The dump file was not written to disk. This might be due to the file system being full.
-------------------	--

Explanation

The dump file was not written to disk. This might be due to the file system being full.

User response

Not applicable.

CMMVC5985E	The action failed because the specified directory is not permitted for this command.
-------------------	---

Explanation

You have attempted to copy, delete, or list dumps from a directory that is not valid. A list of valid directories for these commands is provided in the documentation.

User response

Ensure that the directory you specify is valid, and resubmit the command.

CMMVC5986E	The tracing of I/O operations was not started because the virtual disk (VDisk) or managed disk (MDisk) failed to return any statistics.
-------------------	--

Explanation

The tracing of I/O operations was not started because the volume or managed disk (MDisk) failed to return statistics.

User response

Not applicable.

CMMVC5987E **VALUE is not a valid command line option.**

Explanation

The specified string that you have entered is not a supported command line option.

User response

Specify a supported option, and resubmit the command.

CMMVC5988E **command should not be run by the root userid. Use the admin userid.**

Explanation

This command should not be issued if you are logged in with a root user ID. Use the admin userid.

User response

Log off of the root user ID and log in as admin.

CMMVC5989E **The operation was not performed because the relationship is offline.**

Explanation

The operation was not performed because the relationship is offline.

User response

Not applicable.

CMMVC5990E **The FlashCopy consistency group was not stopped as there are no FlashCopy mappings within the group.**

Explanation

The FlashCopy consistency group was not stopped as there are no FlashCopy mappings within the group.

User response

Not applicable.

CMMVC5991E **The Remote Copy consistency group was not stopped as there are no Remote Copy relationships within the group.**

Explanation

The Remote Copy consistency group was not stopped as there are no Remote Copy relationships within the group.

User response

Not applicable.

CMMVC5992E **The Remote Copy consistency group was not stopped as there are no Remote Copy relationships within the group.**

Explanation

The Remote Copy consistency group was not stopped as there are no Remote Copy relationships within the group.

User response

Not applicable.

CMMVC5993E **The specified update package does not exist.**

Explanation

The specified update package does not exist.

User response

Not applicable.

CMMVC5994E **Error in verifying the signature of the update package.**

Explanation

The system could not verify the signature of the update package due to the following reasons:

- There is not enough space on the system to copy the file.
- The package is incomplete or contains errors.

User response

If the copy failed with an error indicating that there was insufficient space on the system, free up additional space on your system. Otherwise, ensure that the cluster time and date stamp on the signature is correct. (For example, the time and date cannot be in the future.)

CMMVC5995E **An error prevented the unpacking of the update package.**

Explanation

The system disk is too full to allow the update package to be unpacked.

User response

Use the cleardumps command with the parameter - prefix /home/admin/upgrade/ to clear unused files, then reboot the node before attempting to unpack the update package again.

CMMVC5996E The specific update package cannot be installed over the current version.

Explanation

The update package is not compatible with the current version or the system.

User response

Check the available update packages and find the correct update package for your current version and for your system. If the update package is correct for your system, check the version requirements for the package. You might have to update the current version to an intermediate version before you update to the latest version. (For example, if your current version is 1 and you are trying to update to version 3, you might need to update to version 2 before applying the version 3 update.)

CMMVC5999W Featurization for this facility has not been enabled.

Explanation

Featurization for this facility has not been enabled.

User response

Not applicable.

CMMVC6000W Featurization for this facility has not been enabled.

Explanation

Featurization for this facility has not been enabled.

User response

Not applicable.

CMMVC6001E The FlashCopy consistency group was not started as there are no FlashCopy mappings within the group.

Explanation

The FlashCopy consistency group was not started as there are no FlashCopy mappings within the group.

User response

Create a FlashCopy within the appropriate group.

CMMVC6002E This command can only be run on a node that is in the service state.

Explanation

This command can only be run on a node that is in the service state.

User response

Not applicable.

CMMVC6003E This command can not be run on a node that is in the service state.

Explanation

This command can not be run on a node that is in the service state.

User response

Not applicable.

CMMVC6004E The delimiter value *VALUE* is invalid.

Explanation

The specified value is not a valid delimiter value.

User response

Specify a different delimiter.

CMMVC6005E The view request failed as the specified object is not a member of an appropriate group.

Explanation

A view was request on an object that has been incorrectly initialized.

User response

Ensure that the object is correctly initialized before resubmitting the view request.

CMMVC6006E The managed disk (MDisk) was not deleted because the resource was busy.

Explanation

An attempt was made to delete an MDisk from a storage pool that is being used as a source and destination for migration operations.

User response

Ensure that the storage pool is not being used for migration operations before reissuing the command.

CMMVC6007E The two passwords that were entered do not match.

Explanation

The two passwords entered for verification of your password change were not the same.

User response

Re-enter the passwords.

CMMVC6008E The key already exists.

Explanation

An attempt was made to load a duplicate SSH key.

User response

Not applicable.

CMMVC6009E Unable to allocate a block of memory in which to copy the returned data.

Explanation

The command line was unable to allocate a block of memory in which to copy the results of the query.

User response

Resubmit the command. If the problem persists, contact IBM technical support for assistance.

CMMVC6010E Unable to complete the command as there are insufficient free extents, or the command requested an expansion of 0 size.

Explanation

There are not enough free extents to meet the request.

User response

Not applicable.

CMMVC6011E This cluster is part of a remote cluster partnership. Because this

update package will make changes to the cluster state, it cannot be applied to the current code level until all remote cluster partnerships are deleted.

Explanation

You have attempted to apply software when a Remote Copy relationship to a remote cluster exists.

User response

Delete the Remote Copy relationship to the remote clusters, and resubmit the command.

CMMVC6012W The virtualized storage capacity is approaching the amount that you are licensed to use.

Explanation

The requested action has completed. However, the limits permitted by the license you purchased are approaching.

User response

Subsequent actions might require that you increase your licensed limits.

CMMVC6013E The command failed because there is a consistency group mismatch on the aux cluster.

Explanation

The action has failed as there was a difference in attributes between the Metro Mirror consistency groups involved.

User response

Ensure that the attributes of the two Metro Mirror consistency groups match before resubmitting the command.

CMMVC6014E The command failed because the requested object is either unavailable or does not exist.

Explanation

The command failed because the requested object is either unavailable or does not exist.

User response

Ensure that all parameters have been correctly entered. If this is the case determine why the object is unavailable, then resubmit the command.

CMMVC6015E	A delete request is already in progress for this object.
-------------------	---

Explanation

A delete request is already in progress for this object.

User response

Not applicable.

CMMVC6016E	The action failed as there would be, or are, no more disks in the MDisk group.
-------------------	---

Explanation

The action failed as there would be, or are, no more disks in the I/O group.

User response

Ensure that all parameters have been correctly entered.

CMMVC6017E	A parameter or argument contains invalid characters. Ensure that all characters are ASCII.
-------------------	---

Explanation

The command-line interface (CLI) will only accept ASCII input.

User response

Ensure that all input to the CLI is ASCII, then resubmit the command.

CMMVC6018E	The update pre-install process failed.
-------------------	---

Explanation

The update failed as there was an error during the preprocessing. The package is either not valid or corrupted.

User response

Ensure the package is a valid update package. Download the package from the source location again as it might have been corrupted during a network transfer.

CMMVC6019E	The update failed because a node pended.
-------------------	---

Explanation

The update failed because a node pended as the update was in progress.

User response

Ensure that all nodes are online and available before restarting the update process.

CMMVC6020E	The update failed because the system was unable to distribute the package to all of the nodes.
-------------------	---

Explanation

The system could not complete the process of updating files. A full disk is a possible cause.

User response

Ensure that all nodes are online, and use the cleandumps command to clean the updates directory.

CMMVC6021E	The system is currently busy performing another request. Try again later.
-------------------	--

Explanation

The requested action failed as the system is processing another request.

User response

Wait before resubmitting the request.

CMMVC6022E	The system is currently busy performing another request. Try again later.
-------------------	--

Explanation

The requested action failed as the system is processing another request.

User response

Wait before resubmitting the request.

CMMVC6023E	The system is currently busy performing another request. Try again later.
-------------------	--

Explanation

The requested action failed as the system is processing another request.

User response

Wait before resubmitting the request.

CMMVC6024E The auxiliary VDisk entered is invalid.

Explanation

The auxiliary volume is entered as a parameter in the command-line interface is not a valid auxiliary volume.

User response

Select a valid auxiliary volume, and resubmit the command.

CMMVC6025E The RC consistency group Master cluster is not the local cluster.

Explanation

The auxiliary volume is entered as a parameter in the command-line interface is not a valid auxiliary volume.

User response

Resubmit the command with a consistency group that belongs to the local cluster.

CMMVC6026E The RC consistency group is not in the stopped state.

Explanation

The action failed as the Metro Mirror consistency group is not in the stopped state.

User response

Ensure that the Metro Mirror consistency group is in the stopped state before resubmitting the command.

CMMVC6027E The RC consistency group is not the primary master.

Explanation

The RC consistency group requested in the command is not the Metro Mirror primary master.

User response

Ensure that the parameters have been entered correctly on the command line.

CMMVC6028E This package cannot be applied to the current code level because it contains changes to the cluster state and there are remote cluster partnerships defined.

Explanation

The action failed because there is a connected remote cluster. The update cannot be applied because it would put the remote cluster at a different code level than the local cluster.

User response

Ensure that the cluster partnership is unconfigured before resubmitting the command. Ensure that you unconfigure the remote cluster and update the code on it before reconfiguring the cluster partnership.

CMMVC6029E All nodes must have identical code level before a concurrent code update can be performed.

Explanation

The concurrent update failed as two or more nodes were at differing code levels. All nodes must be at the same code level before a software update can be performed.

User response

Use the service assistant to bring all nodes to the same level before resubmitting the concurrent update.

CMMVC6030E The operation was not performed because the FlashCopy mapping is part of a consistency group. The action must be performed at the consistency group level.

Explanation

An attempt was made to stop a FlashCopy mapping. This failed as the FlashCopy mapping is part of a consistency group.

User response

Issue the stop command to the FlashCopy consistency group. This will stop all FlashCopies within that group that are in progress.

CMMVC6031E The operation was not performed because the FlashCopy consistency group is empty.

Explanation

An attempt was made to prestart an empty FlashCopy consistency group.

User response

Not applicable.

CMMVC6032E The operation was not performed because one or more of the entered parameters is invalid for this operation.

Explanation

An parameter that is not valid was entered for the command.

User response

If attempting to change the I/O group to which the volume belongs, ensure that the volume is not already a part of the group.

CMMVC6033E The action failed due to an internal error.

Explanation

An internal error caused the action to fail.

User response

Not applicable.

CMMVC6034E The action failed because the maximum number of objects has been reached.

Explanation

The action failed because the maximum number of objects has been reached.

User response

Not applicable.

CMMVC6035E The action failed as the object already exists.

Explanation

An operation was requested to create an object that already exists.

User response

Ensure that the name you are attempting to apply to a new object does not exist, or change the name before re-issuing the command.

CMMVC6036E An invalid action was requested.

Explanation

The action failed because it is not a valid action with the command that was issued.

User response

Issue an action that is valid with the command.

CMMVC6037E The action failed as the object is not empty.

Explanation

The action failed because an object was specified.

User response

Resubmit the command without specifying an object.

CMMVC6038E The action failed as the object is empty.

Explanation

The action failed because an object was not specified.

User response

Specify an object, and resubmit the command.

CMMVC6039E The action failed as the object is not a member of a group.

Explanation

The action failed because the object is not a member of a group.

User response

Specify an object that is part of a group, and resubmit the command.

CMMVC6040E The action failed as the object is not a parent.

Explanation

The action failed because the object is not a parent object.

User response

Specify an object that is a parent, and resubmit the command.

CMMVC6041E The action failed as the cluster is full.

Explanation

The action failed because the cluster is full.

User response

Remove data from the cluster, and resubmit the command.

CMMVC6042E The action failed as the object is not a cluster member.

Explanation

The action failed because the object is not a member of the cluster.

User response

Specify an object that is a member of the cluster, and resubmit the command.

CMMVC6043E The action failed as the object is a member of a group.

Explanation

The action failed because the object is a member of a group.

User response

Specify an object that is not a member of a group, and resubmit the command.

CMMVC6044E The action failed as the object is a parent.

Explanation

The action failed because the object is a parent object.

User response

Specify an object that is not a parent object, and resubmit the command.

CMMVC6045E The action failed, as the -force flag was not entered.

Explanation

The action failed because the -force option was not entered.

User response

Specify the -force option in the command.

CMMVC6046E The action failed as too many candidates were selected.

Explanation

The action failed because too many candidates were specified.

User response

Specify fewer candidates in the command.

CMMVC6047E The action failed as too few candidates were selected.

Explanation

An action was requested with too few candidate objects.

User response

Determine the correct number of candidates required for the specific command and reissue the command.

CMMVC6048E The action failed as the object is busy.

Explanation

The action failed because the object is busy.

User response

Not applicable.

CMMVC6049E The action failed as the object is not ready.

Explanation

The action failed because the object is not ready.

User response

Not applicable.

CMMVC6050E The action failed as the command was busy.

Explanation

The action failed because the command is busy.

User response

Not applicable.

CMMVC6051E An unsupported action was selected.

Explanation

The action failed because it is not valid with the command.

User response

Specify an action that is valid with the command.

CMMVC6052E The action failed as the object is a member of a FlashCopy mapping.

Explanation

The object is a member of a FlashCopy mapping, thus it cannot be deleted.

User response

Specify an object that is not a member of a FlashCopy mapping, or remove the object from the FlashCopy mapping.

CMMVC6053E An invalid WWPN was entered.

Explanation

A worldwide port name (WWPN) that is not valid was specified.

User response

Specify a valid WWPN.

CMMVC6054E The action failed as not all nodes are online.

Explanation

One or more nodes are not online.

User response

Check that each node is online, and resubmit the command.

CMMVC6055E The action failed as an update is in progress.

Explanation

The action failed because a software update is in progress.

User response

Wait for the software update to complete, and resubmit the command.

CMMVC6056E The action failed as the object is too small.

Explanation

The action failed because the object is too small.

User response

Specify a different object, and resubmit the command.

CMMVC6058E The action failed as the object is in the recovery HWS.

Explanation

An attempt was made to perform an operation on a node that is in the recovery I/O group.

User response

Get the node into one of the other I/O groups and reissue the command.

CMMVC6059E The action failed as the object is in an invalid mode.

Explanation

The action failed because the object is in the wrong mode.

User response

Check that the object is in the correct mode, and resubmit the command.

CMMVC6060E The action failed as the object is being deleted.

Explanation

The action failed because the object is being deleted.

User response

Not applicable.

CMMVC6061E The action failed as the object is being resized.

Explanation

The action failed because the object is being resized.

User response

Check that the object is in the correct mode, and resubmit the command.

CMMVC6062E The action failed as the object is being moved between HWS.

Explanation

An attempt was made to perform an action against an object that is currently being moved between I/O groups.

User response

Re-issue the command when the move operation has completed.

CMMVC6063E The action failed as there are no more disks in the group.

Explanation

An attempt was made to perform an action against a group that contained no disks.

User response

Either add disks to the group and reissue the command, or select another group against which to execute the action.

CMMVC6064E The action failed as the object has an invalid name.

Explanation

An attempt was made to create or rename an object using a name that is not valid.

User response

Use a name that meets the naming standards and reissue the command.

CMMVC6065E The action failed as the object is not in a group.

Explanation

An attempt was made to perform an action on an object that was not in an appropriate group.

User response

Ensure that the object is a member of an appropriate group and reissue the command.

CMMVC6066E The action failed as the system is running low on memory.

Explanation

The system is running low on memory.

User response

Not applicable.

CMMVC6067E The action failed as the SSH key was not found.

Explanation

An attempt was made to perform an action using an SSH key that does not exist.

User response

Reissue the command using a key that does exist.

CMMVC6068E The action failed as there are no free SSH keys.

Explanation

An attempt was made to use an SSH key when there are no free SSH keys.

User response

Upload additional keys and reissue the command.

CMMVC6069E The action failed as the SSH key is already registered.

Explanation

An attempt was made to register an SSH key that was already registered.

User response

Not applicable.

CMMVC6070E An invalid or duplicated parameter, unaccompanied argument, or incorrect argument sequence has been detected. Ensure that the input is as per the help.

Explanation

The parameters entered for a command were not valid.

User response

Correct the parameters and reissue the command.

CMMVC6071E The VDisk-to-host mapping was not created because the VDisk is already mapped to a host.

Explanation

The volume is already mapped to a host.

User response

Not applicable.

CMMVC6073E The maximum number of files has been exceeded.

Explanation

The maximum number of files has been exceeded.

User response

Not applicable.

CMMVC6074E The command failed as the extent has already been assigned.

Explanation

The command failed as the extent has already been assigned.

User response

Assign a different extent, and resubmit the command.

CMMVC6075E	The expand failed as the last extent is not a complete extent.
-------------------	---

Explanation

The expand failed as the last extent is not a complete extent.

User response

Assign a different extent, and resubmit the command.

CMMVC6076E	The command failed because the virtual disk cache is not empty. Either wait for the cache to flush or use the force flag to discard the contents of the cache.
-------------------	---

Explanation

The command failed due to an error during the flushing of the volume.

User response

Not applicable.

CMMVC6077E	WARNING - Unfixed errors should be fixed before applying an update. Depending on the nature of the errors, they might cause the update process to fail. It is highly recommended to fix these errors before proceeding. If a particular error cannot be fixed, contact the support center.
-------------------	---

Explanation

Unfixed errors should be fixed before applying an update. Depending on the nature of the errors, they might cause the update process to fail. It is highly recommended to fix these errors before proceeding.

User response

If the error cannot be fixed, contact the support center.

CMMVC6078E	The action failed because the object is in an invalid mode.
-------------------	--

Explanation

An attempt was made to perform an action against an object in a mode that did not allow for that action to be performed.

User response

Get the object into a suitable mode and reissue the command.

CMMVC6079E	Metadata recovery could not complete the operation because a parameter is invalid.
-------------------	---

Explanation

Metadata recovery could not complete the operation because a parameter is not valid.

User response:

CMMVC6081E	Metadata Recovery is busy processing the previous operation.
-------------------	---

Explanation

Metadata Recovery is busy processing the previous operation.

User response:

CMMVC6082E	The attempt to abort metadata recovery failed because the previous operation has completed.
-------------------	--

Explanation

The attempt to cancel metadata recovery failed because the previous operation has completed.

User response

None.

CMMVC6083E	Metadata recovery could not find a valid dumpfile required for the rebuild operation.
-------------------	--

Explanation

Metadata recovery could not find a valid dumpfile required for the rebuild operation.

CMMVC6084E	Metadata recovery could not create/open/write the scan file, the disk might be full.
-------------------	---

Explanation

Metadata recovery could not create/open/write the scan file, the disk might be full.

User response:

CMMVC6085E	Metadata recovery could not create/open/write the dump file, the disk might be full.
-------------------	---

Explanation

Metadata recovery could not create/open/write the dump file, the disk might be full.

User response:

CMMVC6086E	Metadata recovery could not create/open/write the progress file, the disk might be full.
-------------------	---

Explanation

Metadata recovery could not create/open/write the progress file, the disk might be full.

User response:

CMMVC6087E	Metadata recovery could not map the buffers necessary to complete the operation.
-------------------	---

Explanation

Metadata recovery could not map the buffers necessary to complete the operation.

User response:

CMMVC6088E	The lba at which metadata recovery was requested does not contain metadata.
-------------------	--

Explanation

The lba at which metadata recovery was requested does not contain metadata.

User response:

CMMVC6089E	The metadata at the requested lba is flagged as invalid.
-------------------	---

Explanation

The metadata at the requested lba is flagged as not valid.

User response:

CMMVC6090E	The metadata header checksum verification failed.
-------------------	--

Explanation

The metadata header checksum verification failed.

User response:

CMMVC6091E	The metadata region checksum verification failed.
-------------------	--

Explanation

The metadata region checksum verification failed.

User response

Contact your administrator. Resubmit the command after the administrator confirms that the problem is resolved.

CMMVC6092E	The metadata recovery operation was aborted.
-------------------	---

Explanation

The metadata recovery operation was cancelled.

User response

Check your command and ensure that your input is correct. Resubmit the command. If you get the same error, contact your administrator.

CMMVC6093E	Metadata recovery internal error - (read only)
-------------------	---

Explanation

Metadata recovery internal error - (read only)

User response

Contact your administrator. When the administrator lets you know that the problem has been resolved, resubmit the command.

CMMVC6095E	Metadata recovery encountered the end of the disk.
-------------------	---

Explanation

Metadata recovery encountered the end of the disk.

User response

Contact the administrator and let them know about this error. The administrator must take care of this problem before you can continue.

CMMVC6096E	The metadata recovery task could not be initiated because the required back-end resource could not be found.
-------------------	---

Explanation

The back-end resource that is required for the task is unavailable.

User response:

Ensure that the required back-end resource is available, and reinitiate the task.

CMMVC6097E **The metadata recovery task could not be initiated because the system was unable to send the required I/O to the back-end resource.**

Explanation

The back-end resource is possibly not configured properly.

User response:

Ensure that the required back-end resource is accessible, and reinitiate the task.

CMMVC6098E **The copy failed as the specified node is the configuration node.**

Explanation

The copy failed because the specified node is the configuration node.

User response

Check your command. Correct the specified node and resubmit..

CMMVC6100E ***OPTION* not consistent with *ACTION***

Explanation

The specified option is not supported for the specified action.

User response

Remove the option, and resubmit the command.

CMMVC6101E ***OPTION* not consistent with *OPTION***

Explanation

The two specified options cannot be used together.

User response

Remove one of the options, and resubmit the command.

CMMVC6102E ***OPTION* and *OPTION* are alternatives**

Explanation

The two specified options are alternatives, and cannot be used together.

User response

Remove one of the options, and resubmit the command.

CMMVC6103E **Problem with *FILENAME* : *DETAILS***

Explanation

A problem occurred when opening the specified file. Determine the cause of the problem and correct it before trying again.

User response

Correct the problem, and resubmit the command.

CMMVC6104E **Action *ACTION* not run**

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6105E **Different names for source *SOURCE_CLUSTER_NAME* and target *TARGET_CLUSTER_NAME* clusters**

Explanation

The backup configuration cannot be restored to the target cluster because the source and target cluster have different names.

User response

Perform one of the following actions: (1) Use a different backup configuration. (2) Delete the cluster and recreate it with the same name as that stored in the backup configuration file.

CMMVC6106W **Target cluster has non-default *id_alias* *ALIAS* .**

Explanation

The specified *id_alias* of the target cluster is a non-default value. Clusters should have the default value. The non-default value suggests that the cluster is customized and is not suitable for restoration. Restoration changes the *id_alias*.

User response

Change the *id_alias* to a default value, and resubmit the command.

CMMVC6107E ***NUMBER_OF_OBJECTS* io_grp objects in target cluster; *NUMBER_OF_REQUIRED_OBJECTS* are required**

Explanation

The number of I/O groups in the target cluster is not sufficient to accommodate the I/O groups defined in the backup configuration file. Determine why there are not enough I/O groups.

User response

Correct the problem, and resubmit the command.

CMMVC6108I ***Disk controller system with a WWNN of *WWNN_VALUE* found.***

Explanation

A disk controller system with the required WWNN has been found.

User response

Not applicable.

CMMVC6109E ***Backup file version *version_id* is not compatible with current version *version_id****

Explanation

The backup file was generated on a cluster with a different version number than that of your current system.

User response

Make sure that you are copying the most up-to-date backup file onto the cluster. If you believe your backup file is correct, contact your service support representative.

CMMVC6110E ***Bad code level: *VALUE* .***

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6111E ***The cluster code level could not be determined from *VALUE* .***

Explanation

The code level of the cluster could not be determined. The code level should be of the format x.y.z, where x, y, and z are integers.

User response

If the cause of the problem cannot be determined, contact IBM technical support for assistance.

CMMVC6112W ***OBJECT_TYPE *OBJECT_NAME* has a default name.***

Explanation

An object in the cluster has a default name. This can cause problems when restoring a cluster because default names are changed during restoration. Object IDs are also changed during restoration.

User response

Choose an appropriate name for each object in the cluster, and resubmit the command.

CMMVC6113E ***The command *COMMAND* has failed with return code *RETURN_CODE* .***

Explanation

An attempt to run a command remotely failed using secure communications.

User response

Determine the cause of the problem, and resubmit the command. Specific steps are dependent on what command was running and what return code was given.

CMMVC6114E ***No help for action *ACTION* .***

Explanation

There is no help for the specified action topic.

User response

Not applicable.

CMMVC6115W ***Feature *FEATURE_PROPERTY* mismatch: *VALUE* expected; *VALUE* found.***

Explanation

The features in the backup configuration file and the target cluster do not match. There should be an exact match between the two. Nevertheless, the restore of the configuration can continue.

User response

Not applicable.

CMMVC6116I **Feature match for *FEATURE* .**

Explanation

The features in the backup configuration file and the target cluster are an exact match.

User response

Not applicable.

CMMVC6117E ***FIX_OR_FEATURE* is not available.**

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6118I ***TYPE* with *PROPERTY PROPERTY_VALUE* and *PROPERTY PROPERTY_VALUE* found.**

Explanation

An object in the cluster has been found with the correct properties.

User response

Not applicable.

CMMVC6119E ***TYPE* with *PROPERTY PROPERTY_VALUE* not found.**

Explanation

An object in the cluster with the correct properties has not been found. Restoration cannot proceed without the object.

User response

Determine why the object cannot be found. Ensure that the object is available, and resubmit the command.

CMMVC6120E **Target is not the configuration node**

Explanation

The target is not the configuration node.

User response

Redirect the action against the configuration node, and resubmit the command.

CMMVC6121E **No cluster id or id_alias in backup configuration.**

Explanation

Neither the cluster id_alias nor the ID can be extracted from the backup configuration file.

User response

If the cause of the problem cannot be determined, contact IBM technical support for assistance.

CMMVC6122E **No *TYPE* with *PROPERTY VALUE* is present in the table.**

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6123E **No *PROPERTY* for *TYPE NAME* .**

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6124E **No *TYPE* with *PROPERTY VALUE***

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6125E **No unique ID for *TYPE NAME***

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6126E **No *TYPE* with unique ID *VALUE***

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6127I The SSH key *IDENTIFIER* for *USER* is already defined; the SSH key will not be restored

Explanation

An identical SSH key for this user is already defined on the cluster. Therefore, the key in the backup file will not be restored.

User response

Specify a different SSH key, and resubmit the command.

CMMVC6128W *DIRECTORY*

Explanation

The files in the specified directory cannot be listed.

User response

Determine why the files cannot be listed, correct the problem, and resubmit the command.

CMMVC6129E VDisk-to-host mapping objects have VDisk_UID values that are not consistent.

Explanation

All of the host mapping objects do not have the same number for the volume LUN instance. Therefore, there is a possibility the backup configuration file is corrupt. The LUN instance number should be the same for all host mapping objects that are associated with a specific volume. The LUN instance number is incorporated into the volume ID property.

User response

Determine why the LUN instance number is not the same, correct the problem, and resubmit the command.

CMMVC6130W Inter-cluster *PROPERTY VALUE* will not be restored.

Explanation

The restoration of inter-cluster objects is not supported.

User response

Not applicable.

CMMVC6131E No location cluster information

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6132E The object *OBJECT* of type *TYPE* has a property *PROPERTY* with an incorrect value *INCORRECT_VALUE*. The operation cannot proceed until the property has the correct value *CORRECT_VALUE*. Take administrative action to change the value and try again.

Explanation

The specified object has the specified property of the specified type with the specified incorrect value. The property most likely reflects the state of the object.

User response

Change the state to the required value, and resubmit the command.

CMMVC6133E Required *TYPE* property *PROPERTY* not found

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6134E No argument for *OPTION*

Explanation

No argument has been supplied for the specified option, which requires an argument.

User response

Supply an argument, and resubmit the command.

CMMVC6135E Argument *VALUE* for *OPTION* is not valid.

Explanation

The specified argument that you have supplied is not valid for the specified option.

User response

Supply an valid argument, and resubmit the command.

CMMVC6136W No SSH key file *FILENAME*

Explanation

The specified file, which should contain the SSH key, is not present and will not be restored. The backup operation will continue.

User response

No action is required. You might have to manually restore the key.

CMMVC6137W No SSH key file *FILENAME*; key not restored

Explanation

An SSH key cannot be restored because the specified file, which is expected to contain the SSH key, is not present. The restore operation will continue.

User response

After the restore is complete, locate the file containing the key, and perform one of the following actions: (1) Rename the file so that it has the correct name, and resubmit the command. (2) Restore the key manually using the addsshkey command.

CMMVC6138E *OPTION* is required

Explanation

An option is missing. The option might be listed as optional, but circumstances make the option mandatory.

User response

Supply the option, and resubmit the command.

CMMVC6139E Incorrect XML tag nesting in *FILENAME*

Explanation

There is a problem with the content of a configuration file. There is a problem parsing the XML in the file, because the XML records are not consistent. The file might be corrupt, or the file has been truncated.

User response

Replace this copy with a good copy, and resubmit the command. If the problem persists, contact IBM technical support for assistance.

CMMVC6140E No default name for type *TYPE*

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6141E The option *OPTION* does not support an argument.

Explanation

An argument has been supplied for an option that does not support one.

User response

Remove the argument, and resubmit the command.

CMMVC6142E Existing *OBJECT_TYPE* *OBJECT_NAME* has a non-default name.

Explanation

The specified object in the target default cluster has a non-default name. This suggests that the cluster was customized. The cluster is therefore not suitable for restoration.

User response

Reset the cluster as per the instructions for restoring the cluster configuration, and resubmit the command.

CMMVC6143E The required configuration file *FILENAME* does not exist.

Explanation

A file that is critical for successful operation is missing.

User response

Check your command. Specify the correct configuration file and resubmit the command.

CMMVC6144W The object with default name *NAME* has been restored as *SUBSTITUTE_NAME*.

Explanation

An object with a default name has been restored with a different name. Ensure that you account for this name change when using the restored cluster in the future. To avoid this problem in the future, choose an appropriate name for each object in the cluster.

User response

Choose an appropriate name for each object in the cluster.

CMMVC6145I **First use the *COMMAND* -prepare command.**

Explanation

This advisory is given prior to CMMVC6103E when an intermediate file is missing.

User response

.The command you submitted cannot be processed at the moment. Follow the message and submit a different command first.

CMMVC6146E **Problem parsing *OBJECT_TYPE* data: *LINE***

Explanation

An unexpected error has occurred.

User response

Contact the support center.

CMMVC6147W ***TYPE NAME* has a name beginning with *PREFIX* .**

Explanation

An object has been encountered that has a name beginning with the specified reserved prefix. The only valid reason for an object with this kind of name is that a restoration command did not complete successfully.

User response

Ensure that no object uses the reserved prefix in its name, and resubmit the command.

CMMVC6148E **Target cluster has *NUMBER_OF_EXISTING_OBJECTS* objects of type *TYPE* instead of *NUMBER_OF_REQUIRED_OBJECTS* .**

Explanation

The target cluster does not have the specified required number of objects of the specified type.

User response

Correct the problem, and resubmit the command.

CMMVC6149E **An action is required.**

Explanation

An action is required to run the command.

User response

Supply an action, and resubmit the command.

CMMVC6150E **The action *ACTION* is not valid.**

Explanation

The specified action that you have entered is not valid.

User response

Specify a valid action, and resubmit the command.

CMMVC6151E **The option *OPTION* is not valid.**

Explanation

The specified option that you have entered is not valid.

User response

Specify a valid option, and resubmit the command.

CMMVC6152E **VDisk *VDISK_NAME* instance number *INSTANCE_NUMBER* is not valid.**

Explanation

The volume cannot be restored because the instance number, which must be a hexadecimal number, is not valid.

User response

Contact IBM technical support for assistance.

CMMVC6153E ***OBJECT* not consistent with *ACTION***

Explanation

The specified object is not supported for the specified action.

User response

Remove the object, and resubmit the command.

CMMVC6154E **Required *OBJECT_TYPE* property *PROPERTY_NAME* has a null value.**

Explanation

An unexpected error has occurred.

User response

Contact IBM technical support for assistance.

CMMVC6155I The command *COMMAND* processing has completed successfully.

Explanation

Only information and warning messages are issued.

User response

Not applicable.

CMMVC6156W *COMMAND* processing completed with errors.

Explanation

Processing was not successful.

User response

Not applicable.

CMMVC6157E Object is required.

Explanation

An object or target was not specified for the command.

User response

Refer to the documentation for the command and specify all required parameters.

CMMVC6164E *variable_error_message*

Explanation

This message is generated by the system and varies depending on the circumstances in which it was created.

User response

For help with a specific message, contact your service support representative.

CMMVC6165E The target is not the original configuration node with a WWNN of *WWNN_VALUE* .

Explanation

A backup configuration can only be restored to the original configuration node.

1928 Spectrum Virtualize for SAN Volume Controller, FlashSystem, and Storwize Family: Command-Line Interface User's Guide

User response

Re-create the default cluster with the correct configuration node, and resubmit the command.

CMMVC6166E The property *PROPERTY* of the object *OBJECT* has changed during *svconfig restore -execute*.

Explanation

The integrity of the restoration cannot be guaranteed.

User response

Resubmit the command from *svconfig restore -prepare*.

CMMVC6169E *variable_error_message*

Explanation

This message is generated by the system and varies depending on the circumstances in which it was created.

User response

For help with a specific message, contact your service support representative.

CMMVC6171I *percentage%* metadata compression

Explanation

The message displays the extent of metadata compression.

User response

This message is informational only. No action is required.

CMMVC6174I Pausing for *num_minutes* minute(s) after node addition(s)

Explanation

The system must process the addition of one or more nodes for the amount of time that is displayed.

User response

This message is informational only. No action is required.

CMMVC6175I Resuming after pause

Explanation

The system completed processing the addition of one or more nodes.

User response

This message is informational only. No action is required.

CMMVC6180E ***object_type [object_id] not restored because [object_type | object_property] is missing***

Explanation

The error message has two variants. One specifies a missing object type, such as a drive, and the other specifies a missing object property, such as a name. In either case, the system cannot continue with object creation because of the missing object or property.

User response

Add the specified object or property to the system. If you believe that the object or property already exists, contact your service support representative.

CMMVC6180W ***object_type object_identifier not restored because object with property property_value is missing***

Explanation

The system cannot continue with object creation because a dependent object is missing.

User response

Add the specified dependent object to the system. If you believe that the object already exists, contact your service support representative.

CMMVC6181E ***object_type object_id has property property_value; should be property_value_in_backup[; use -force to override | overridden]***

Explanation

The displayed object has a property value in its configuration that does not match the value for that property in the backup.

User response

Check the properties in the current configuration. The error message might include one of the following additions:

use -force to override

If this version of the message is displayed, you can retry the command with the addition of the -**force** parameter to retain the property value that is in the current configuration.

overridden

This version of the message is displayed for informational purposes only. The property value in the current configuration is retained. No user action is required.

Otherwise, you must correct the property value in the current configuration before you retry the command.

CMMVC6182E ***object_type object_name with property property_value cannot be [restored | backed up].***

Explanation

Either the displayed object was not restored, or was not backed up, as shown.

User response

The user response is different for each object type. Contact your service support representative.

CMMVC6186E ***io_grp io_group_name restored with id new_id instead of old_id .***

Explanation

This situation can occur when the configuration node is different from the node that was used to create the original cluster. This change affects the SCSI Inquiry value for the I/O group.

User response

This message is a warning only. No user response is required.

CMMVC6187W ***Extraneous object_type object_name discovered***

Explanation

Recovery identified an extraneous object of the displayed type and named it *object_name*.

User response

This message is only a warning. No action is required.

CMMVC6188W ***VARIANT #1: Current Config inconsistent with backup
object_type object_id does not exist in backup
VARIANT #2: Current Config inconsistent with backup***

object_type object_id now has
wrong_property wrong_value was
correct_value

Explanation

VARIANT #1: The object of the displayed type and ID is in the current configuration but not in the backup file. The object will not be recovered.

VARIANT #2: The recovery process found an inconsistency. The object of the displayed type and ID now has a property with an incorrect value.

User response

VARIANT #1: Re-create the missing object in the backup file after the recovery process is complete.

VARIANT #2: Manually restore the correct value after the recovery process is complete.

CMMVC6189W E-mail server settings could not be restored due to missing configuration information

Explanation

An attempt was made to restore email server settings that were not found on the backup device.

User response

Make sure that you specified the correct email server and that you made no typographical errors. If everything looks correct, contact your service support representative.

CMMVC6200E Discovery did not complete within time limit - check that this is expected

Explanation

User response

Contact IBM Support.

CMMVC6201E System layer must be changed to *new_layer* using chsystem before configuration can be restored

Explanation

User response

Contact IBM Support.

CMMVC6202E This command can only be run by the superuser

Explanation

User response

Contact IBM Support.

CMMVC6203E Enclosure serial number *serial_no* was found for enclosure ID *enclosure_1* but it is already in use for enclosure ID *enclosure_2*

Explanation

User response

Contact IBM Support.

CMMVC6204E Node *node_name* in backup is part of *io_grp io_group_1*, but the node is currently set to *io_grp io_group_2*

Explanation

User response

Contact IBM Support.

CMMVC6205E Cannot retrieve VPD for node *node_name* because it is currently in service mode.

Explanation

User response

Contact IBM Support.

CMMVC6206E Timeout exceeded waiting for *object_type object_id* to have expected *property_name expected_value*, actual *actual_value*.

Explanation

User response

Contact IBM Support.

CMMVC6207E Cannot restore encryption as more USB devices are required. Required *req_number_devices* device(s) but found *actual_number_devices* device(s).

Explanation

User response

Add the required number of USB devices and retry the command.

CMMVC6208E	The <i>feature_id</i> feature cannot be partially configured prior to a restore operation. The current state is <i>current_state</i>.
-------------------	--

Explanation

User response

Contact IBM Support.

CMMVC6209E	Unable to determine system code version.
-------------------	---

Explanation

User response

Contact IBM Support.

CMMVC6210E	Current Config inconsistent with backup because metadatavdisk with vdisk_id <i>volume_id</i> already exists.
-------------------	---

Explanation

User response

Contact IBM Support.

CMMVC6211E	The system contains fewer USB ports than required to recover encryption automatically. Manually set up encryption and then run the -prepare command again.
-------------------	---

Explanation

User response

Manually set up encryption and then run the -**prepare** command again.

CMMVC6212E	The host port mode did not change to transitional within the time limit.
-------------------	---

Explanation

The value of the `fc_targetportmode` variable should change to transitional within 1 minute. If it does not, the T4 recovery fails.

User response

Contact IBM Support.

CMMVC6213E	Active-active remote copy relationship <i>relationship_id</i> not added to consistency group <i>group_id</i>.
-------------------	--

Explanation

User response

Contact IBM Support.

CMMVC6214E	The system could not be restored because the backup configuration contains a hybrid system of Storwize V7000 Gen1 and Storwize V7000 Gen2 nodes. Currently this cluster is not Storwize V7000 Gen1 compatible.
-------------------	---

Explanation

An attempt is being made to recover a hybrid system from a config node. If you continue, the system cannot add Storwize V7000 Gen1 nodes and the system will be re-created with Storwize V7000 Gen1 compatibility mode disabled. You cannot read any Storwize V7000 Gen1 nodes to the system.

User response

If you continue, a former hybrid system will be re-created as a system exclusively. To continue to use a hybrid system, restart the recovery from a Storwize V7000 Gen1 node.

CMMVC6215W	Ensure that the system certificate is trusted by all key servers before running execute.
-------------------	---

Explanation

A new cluster was created as part of the T4 store process. The new cluster has a new cluster (client) certificate. This certificate must be exported and installed on all key servers so that subsequent recovery commands in the execute phase, such as **mkkeyserver**, succeed.

User response

The system SSL certificate must be trusted by all key servers before you run the **svconfig restore -execute** command. To export the system certificate, use the **chsystemcert -export** command and then install the certificate on the key servers. Alternately, to generate a signing request to be signed by a certificate authority, use the **chsystemcert -mkrequest** command and provide the Certificate Signing Request (CSR) to the certificate authority. To install the signed certificate, use the **chsystemcert -install -file** command.

CMMVC6216E Failed to generate key server certificates from the backup file.

Explanation

As part of the T4 restore script, if a key server configuration existed in the backup, key server SSL certificates are regenerated and written to new files, which are then used by the restore process. This error means that the restore process failed to regenerate the key server certificates.

User response

Contact your service support representative to manually restore the key server configuration, including server certificates.

CMMVC6218E The KeySecure username and password configuration must match the backup configuration before continuing. Current settings: username_set:%1, password_set:%2. Backup settings: username_set:%3, password_set:%4

Explanation

The T4 recovery script checks that the current Gemalto SafeNet KeySecure user name and password settings match the settings in the backup file. This error is displayed when the settings do not match, and must be configured before the recovery process can continue.

User response

Confirm that the correct configuration backup file is being used. Configure the KeySecure user name and password settings, and then continue by running the **svconfig restore -prepare** command.

CMMVC6219E The key server SSL certificates cannot be restored automatically from the backup. Manually set up

key server encryption and then run the -prepare command again.

Explanation

If key server configuration exists in the backup that is being restored during Tier 4 (T4) recovery, any key server SSL certificates are regenerated and written to new files that are used by the restoration process. This error occurs when the restoration process fails to regenerate the key server certificates because they are too large. This error typically occurs when multiple certificates are supplied, for example when a certificate chain is used.

User response

Manually configure key server encryption by using either the management GUI or the CLI, and then run the **svconfig restore -prepare** command again.

CMMVC6220E The LDAP administrator password cannot be restored automatically from the backup. Manually set the password and then run the -prepare command again.

Explanation

This error occurs when the LDAP administrator password cannot be restored automatically because the required cluster AES key is no longer available.

User response

Use the **chldap -username LDAP_admin_username -password password** command to set the LDAP administrator user name and password manually. Then, retry the command.

CMMVC6231E The action failed as the audit table is full.

Explanation

The action failed because the audit table is full.

User response

Save the audit log to disk and resubmit the command.

CMMVC6300E The create failed because the source and target VDisks are members of FlashCopy mappings that belong to different I/O groups.

Explanation

All FlashCopy mappings in a tree of connected mappings must be in the same I/O group. The new FlashCopy mapping that you attempted to create would have linked two existing trees that are in different I/O groups.

User response

You have three options. The first option is to resubmit the command and specify a different source or target volume. The second option is to delete all of the existing mappings that contain the source volume and resubmit the command. The third option is to delete all of the existing mappings that contain the target volume and resubmit the command.

CMMVC6301E	The create failed because the specified consistency group does not exist.
-------------------	--

Explanation

The FlashCopy mapping was not created because the consistency group that you specified does not exist. You must create a consistency group before you can place a mapping in that group.

User response

Either create the FlashCopy consistency group that you specified and resubmit the command, or resubmit the command and specify an existing consistency group.

CMMVC6302E	The create failed because the resulting tree of FlashCopy mappings would exceed the upper limit.
-------------------	---

Explanation

Either the source volume or the target volume, or both, are already members of other FlashCopy mappings. The FlashCopy mapping was not created because the new FlashCopy mapping that you attempted to create would have linked two existing mapping trees into a single tree that exceeds the maximum number of mappings that are supported for a single tree.

User response

You have two options. The first option is to resubmit the command and specify a different source or target volume. The second option is to delete a sufficient number of the existing FlashCopy mappings in which either the source or the target volume is a member so that the combined mapping tree does not exceed the

maximum number of mappings that are supported for a single tree, and resubmit the command.

CMMVC6303E	The create failed because the source and target VDisks are the same.
-------------------	---

Explanation

A particular volume cannot be both the source and the target in a FlashCopy mapping. The FlashCopy mapping was not created because you have specified the same volume as both the source and the target.

User response

Resubmit the command and specify source and target volumes that are not identical.

CMMVC6304E	The create failed because the source VDisk does not exist.
-------------------	---

Explanation

You must specify an existing volume as the source of a FlashCopy mapping. The FlashCopy mapping was not created because the source volume that you specified does not exist.

User response

Either create the source volume that you specified and resubmit the command, or resubmit the command and specify an existing volume as the source.

CMMVC6305E	The create failed because the target VDisk does not exist.
-------------------	---

Explanation

You must specify an existing volume as the target of a FlashCopy mapping. The FlashCopy mapping was not created because the target volume that you specified does not exist.

User response

Either create the target volume that you specified and resubmit the command, or resubmit the command and specify an existing volume as the target.

CMMVC6306E	The create operation failed because the source VDisk is the member of a FlashCopy mapping whose grain size is different to that specified.
-------------------	---

Explanation

All FlashCopy mappings that are in a tree of connected mappings must have the same grain size. The

FlashCopy mapping was not created because the source volume that you specified is either the source or the target volume of another FlashCopy mapping, and the grain size of the other mapping is different from the grain size that you specified for the mapping that you attempted to create.

User response

You have two options. The first option is to delete all of the FlashCopy mappings that contain the source volume that you specified where the grain size of the FlashCopy mapping is different from the grain size that you specified, and resubmit the command. The second option is to resubmit the command and do not specify the grain size attribute.

CMMVC6307E	The create operation failed because the target VDisk is the member of a FlashCopy mapping whose grain size is different to that specified.
-------------------	---

Explanation

All FlashCopy mappings that are in a tree of connected mappings must have the same grain size. The FlashCopy mapping was not created because the target volume that you specified is either the source or the target volume of another FlashCopy mapping, and the grain size of the other mapping is different from the grain size that you specified for the mapping that you attempted to create.

User response

You have two options. The first option is to delete all of the FlashCopy mappings that contain the target volume that you specified where the grain size of the FlashCopy mapping is different from the grain size that you specified, and resubmit the command. The second option is to resubmit the command and do not specify the grain size attribute.

CMMVC6308E	The create operation failed because the source VDisk is the member of a FlashCopy mapping whose IO group is different to that specified.
-------------------	---

Explanation

All FlashCopy mappings in a tree of connected mappings must be in the same I/O group. The FlashCopy mapping was not created because the source volume that you specified is the source or target volume in another FlashCopy mapping and the I/O group of the other FlashCopy mapping is different from the I/O group that you specified.

User response

You have two options. The first option is to delete all of the FlashCopy mappings that contain the source volume that you specified where the FlashCopy mapping is in a different I/O group from the I/O group that you specified, and resubmit the command. The second option is to resubmit the command and do not specify the I/O group attribute. If you perform the second option, the default value of the I/O group attribute is used.

CMMVC6309E	The create operation failed because the target VDisk is the member of a FlashCopy mapping whose IO group is different to that specified.
-------------------	---

Explanation

All FlashCopy mappings in a tree of connected mappings must be in the same I/O group. The FlashCopy mapping was not created because the target volume that you specified is the source or target volume in another FlashCopy mapping and the I/O group of the other FlashCopy mapping is different from the I/O group that you specified.

User response

You have two options. The first option is to delete all of the FlashCopy mappings that contain the target volume that you specified where the FlashCopy mapping is in a different I/O group from the I/O group that you specified, and resubmit the command. The second option is to resubmit the command and do not specify the I/O group attribute. If you perform the second option, the default value of the I/O group attribute is used.

CMMVC6310E	The modify failed because the specified FlashCopy mapping does not exist.
-------------------	--

Explanation

You cannot modify a FlashCopy mapping that does not exist. The modify command failed because the FlashCopy mapping that you specified does not exist.

User response

Resubmit the command and specify an existing FlashCopy mapping.

CMMVC6311E	The command failed because the source VDisk is the target of a FlashCopy mapping that is in the specified consistency group.
-------------------	---

Explanation

A particular volume cannot be both the source of one FlashCopy mapping and the target of another FlashCopy mapping in the same consistency group. The FlashCopy mapping was not created because the source volume of the FlashCopy mapping that you attempted to create is already the target volume of a FlashCopy mapping in the consistency group that you specified.

User response

Resubmit the command and specify a different consistency group.

CMMVC6312E The command failed because the target VDisk is the source of a FlashCopy mapping that is in the specified consistency group.

Explanation

A particular volume cannot be both the source of one FlashCopy mapping and the target of another FlashCopy mapping in the same consistency group. The FlashCopy mapping was not created because the target volume of the FlashCopy mapping that you attempted to create is already the source volume of a FlashCopy mapping in the consistency group that you specified.

User response

Resubmit the command and specify a different consistency group.

CMMVC6313E The command failed because the specified background copy rate is invalid.

Explanation

The command failed because the background copy rate that you specified is not a supported value.

User response

Either resubmit the command and specify a supported value for the background copy rate, or resubmit the command and do not specify the background copy rate attribute. If you do not specify the background copy rate attribute, the default background copy rate value is used.

CMMVC6314E The command failed because the specified cleaning rate is not valid.

Explanation

The command failed because the cleaning rate that you specified is not a supported value.

User response

Either resubmit the command and specify a supported value for the cleaning rate, or resubmit the command and do not specify the cleaning rate attribute. If you do not specify the cleaning rate attribute, the default cleaning rate value is used.

CMMVC6315E The command failed because the specified grain size is not valid.

Explanation

The command failed because the grain size that you specified is not a supported value.

User response

Either resubmit the command and specify a supported value for the grain size, or resubmit the command and do not specify the grain size attribute. If you do not specify the grain size attribute, the default grain size value is used.

CMMVC6319E The command has failed because a combination of IPv4 and IPv6 parameters were entered.

Explanation

The task accepts either IPv4 or IPv6 parameters. You cannot specify a combination of IPv4 and IPv6 parameters for this task.

User response

Specify only IPv4 or only IPv6 parameters, and resubmit the task.

CMMVC6320E The command has failed because the IPv4 address is not valid.

Explanation

The valid IPv4 address format is d.d.d.d, where d is a decimal value from 0-255.

User response

Specify a valid IPv4 address, and resubmit the task.

CMMVC6321E The command has failed because the IPv4 subnet mask is not valid.

Explanation

The valid IPv4 address format is d.d.d.d, where d is a decimal value from 0-255.

User response

Specify a valid IPv4 subnet mask, and resubmit the task.

CMMVC6322E **The command has failed because the IPv4 gateway address is not valid.**

Explanation

The valid IPv4 address format is d.d.d.d, where d is a decimal value from 0-255.

User response

Specify a valid IPv4 gateway address, and resubmit the task.

CMMVC6323E **The command has failed because the IPv6 address is not valid.**

Explanation

Valid IPv6 address formats are:

- x:x:x:x:x:x:x
- x:x:x:x:x:d.d.d.d

where d is a decimal value from 0-255 of an IPv4 address and x is a hexadecimal value of an IPv6 address.

A special syntax is available to compress long strings of zero bits. The use of '::' indicates multiple groups of zeros. The '::' can appear only once in an address. The '::' can also be used to compress the leading or trailing zeros in an address.

- Example: 123.123.123.123
- Example: 1080:0:0:0:8:800:200C:417A, which can be compressed to 1080::8:800:200C:417A
- Example: 0:0:0:0:0:FFFF:129.144.52.38, which can be compressed to ::FFFF:129.144.52.38
- Example: 0:0:0:0:0:0:13.1.68.3, which can be compressed to ::13.1.68.3

User response

Specify a valid IPv6 address, and resubmit the task.

CMMVC6324E **The command has failed because the IPv6 prefix is not valid.**

Explanation

The value that you entered for an IPv6 address prefix is not a valid IPv6 address prefix.

User response

Specify a valid IPv6 address prefix, and resubmit the task.

CMMVC6325E **The command has failed because the IPv6 gateway address is not valid.**

Explanation

Valid IPv6 address formats are:

- x:x:x:x:x:x:x
- x:x:x:x:x:d.d.d.d

where d is a decimal value from 0-255 of an IPv4 address and x is a hexadecimal value of an IPv6 address.

A special syntax is available to compress long strings of zero bits. The use of '::' indicates multiple groups of zeros. The '::' can appear only once in an address. The '::' can also be used to compress the leading or trailing zeros in an address.

- Example: 123.123.123.123
- Example: 1080:0:0:0:8:800:200C:417A, which can be compressed to 1080::8:800:200C:417A
- Example: 0:0:0:0:0:FFFF:129.144.52.38, which can be compressed to ::FFFF:129.144.52.38
- Example: 0:0:0:0:0:0:13.1.68.3, which can be compressed to ::13.1.68.3

User response

Specify a valid IPv6 gateway address, and resubmit the task.

CMMVC6326E **The command has failed because the IPv4 service state address is not valid.**

Explanation

The valid IPv4 address format is d.d.d.d, where d is a decimal value from 0-255.

User response

Specify a valid IPv4 service state address, and resubmit the task.

CMMVC6327E **The command has failed because the IPv6 service state address is not valid.**

Explanation

Valid IPv6 address formats are:

- x:x:x:x:x:x:x
- x:x:x:x:x:d.d.d.d

where d is a decimal value from 0-255 of an IPv4 address and x is a hexadecimal value of an IPv6 address.

A special syntax is available to compress long strings of zero bits. The use of '::' indicates multiple groups of zeros. The '::' can appear only once in an address. The '::' can also be used to compress the leading or trailing zeros in an address.

- Example: 123.123.123.123
- Example: 1080:0:0:0:8:800:200C:417A, which can be compressed to 1080::8:800:200C:417A
- Example: 0:0:0:0:FFFF:129.144.52.38, which can be compressed to ::FFFF:129.144.52.38
- Example: 0:0:0:0:0:13.1.68.3, which can be compressed to ::13.1.68.3

User response

Specify a valid IPv6 service state address, and resubmit the task.

CMMVC6328E **The command has failed because the console address is not valid.**

Explanation

The valid IPv4 address format is d.d.d.d, where d is a decimal value from 0-255.

Valid IPv6 address formats are:

- x:x:x:x:x:x:x
- x:x:x:x:x:d.d.d.d

where d is a decimal value from 0-255 of an IPv4 address and x is a hexadecimal value of an IPv6 address.

A special syntax is available to compress long strings of zero bits. The use of '::' indicates multiple groups of zeros. The '::' can appear only once in an address. The '::' can also be used to compress the leading or trailing zeros in an address.

- Example: 123.123.123.123
- Example: 1080:0:0:0:8:800:200C:417A, which can be compressed to 1080::8:800:200C:417A
- Example: 0:0:0:0:FFFF:129.144.52.38, which can be compressed to ::FFFF:129.144.52.38
- Example: 0:0:0:0:0:13.1.68.3, which can be compressed to ::13.1.68.3

User response

Specify a valid console address, and resubmit the task.

CMMVC6329E **The command has failed because the IP address or DNS is not valid.**

Explanation

The valid IPv4 address format is d.d.d.d, where d is a decimal value in the range 0 - 255.

Valid IPv6 address formats are:

- x:x:x:x:x:x:x
- x:x:x:x:x:d.d.d.d

where d is a decimal value in the range 0 - 255 of an IPv4 address and x is a hexadecimal value of an IPv6 address.

A special syntax is available to compress long strings of zero bits. The use of '::' indicates multiple groups of zeros. The '::' can appear only once in an address. The '::' can also be used to compress the leading or trailing zeros in an address.

- Example: 123.123.123.123
- Example: 1080:0:0:0:8:800:200C:417A, which can be compressed to 1080::8:800:200C:417A
- Example: 0:0:0:0:FFFF:129.144.52.38, which can be compressed to ::FFFF:129.144.52.38
- Example: 0:0:0:0:0:13.1.68.3, which can be compressed to ::13.1.68.3

User response

Retry the command, specifying a valid IP address or DNS name.

CMMVC6330E **The command has failed because an IPv6 address was specified and the cluster does not have an IPv6 address.**

Explanation

The cluster can only communicate with a server through an IPv6 address if an IPv6 cluster management IP address is configured.

User response

Either configure the cluster to have an IPv6 cluster management address or specify an IPv4 address, and resubmit the task.

Note: You do not need to remove the IPv4 address if you configure the cluster to have an IPv6 cluster management address.

CMMVC6331E **The command has failed because an IPv4 address was specified and the cluster does not have an IPv4 address.**

Explanation

The cluster can only communicate with a server through an IPv4 address if an IPv4 cluster management IP address is configured.

User response

Either configure the cluster to have an IPv4 cluster management address or specify an IPv6 address, and resubmit the task.

Note: You do not need to remove the IPv6 address if you configure the cluster to have an IPv4 cluster management address.

CMMVC6332E **The command has failed because an IPv6 email server address was specified and the cluster does not have an IPv6 address.**

Explanation

The cluster can only communicate with a server through an IPv6 address if an IPv6 cluster management IP address is configured.

User response

Either configure the cluster to have an IPv6 cluster management address or use an email server that has an IPv4 address, and resubmit the task.

Note: You do not need to remove the IPv4 address if you configure the cluster to have an IPv6 cluster management address.

CMMVC6333E **The command has failed because an IPv4 email server address was specified and the cluster does not have an IPv4 address.**

Explanation

The cluster can only communicate with a server through an IPv4 address if an IPv4 cluster management IP address is configured.

User response

Either configure the cluster to have an IPv4 cluster management address or use an email server that has an IPv6 address, and resubmit the task.

Note: You do not need to remove the IPv6 address if you configure the cluster to have an IPv4 cluster management address.

CMMVC6334E **The command failed as the email port number supplied is invalid.**

Explanation

The value that you entered for an email port number is not a valid email port number.

User response

Specify a valid email port number, and resubmit the task.

CMMVC6335E **The command failed as the combination of parameters provided are either mutually incompatible or would leave the cluster without a functioning protocol stack.**

Explanation

You have submitted a task with a combination of parameters and parameter values that is not supported or that does not provide the minimum amount of required information.

User response

Ensure that you specify a supported combination of parameters and parameter values, and resubmit the task.

CMMVC6336E **The virtual disk (VDisk) copy was not created because the grain size must be 32, 64, 128 or 256.**

Explanation

You have supplied an incorrect value for the -grainsize parameter when you attempted to create a thin-provisioned volume copy.

User response

Specify a supported grain size, and resubmit the command.

CMMVC6337E **The action failed because the warning size must be a multiple of 512 bytes.**

Explanation

You are attempting to create a thin-provisioned volume copy but you have entered an incorrect value for the -warning parameter. The value can either be a

percentage of the volume capacity or an absolute value that is a multiple of 512 bytes.

User response

Enter a supported warning value, and resubmit the command.

CMMVC6338E	The action failed because the warning size can not be larger than the virtual size.
-------------------	--

Explanation

You are attempting to create a thin-provisioned volume copy but you have entered an incorrect value for the -warning parameter. The warning value cannot be greater than the volume capacity.

User response

Enter a supported warning value, and resubmit the command.

CMMVC6339E	The virtual disk (VDisk) copy was not created because the virtual size was not provided.
-------------------	---

Explanation

You are attempting to create an image-mode thin-provisioned volume but you did not set the -size parameter.

User response

Resubmit the command using the -size parameter.

CMMVC6340E	The action failed because the value supplied for real size is not a multiple of 512 bytes.
-------------------	---

Explanation

You are attempting to create or resize a thin-provisioned volume copy but you have entered an incorrect value for the -rsize parameter. All sizes must be integer multiples of 512 bytes.

User response

Resubmit the command using a supported -rsize parameter value.

CMMVC6341E	The action failed because the virtual disk (VDisk) copy is not space-efficient or compressed.
-------------------	--

Explanation

You are attempting to run a command that is valid only for thin-provisioned or compressed volumes.

User response

Specify a thin-provisioned or compressed volume, and resubmit the command.

CMMVC6342E	The virtual disk (VDisk) copy was not shrunk because its real size cannot be less than its used size.
-------------------	--

Explanation

You are attempting to reduce the real size that is allocated to a thin-provisioned volume copy, but the command cannot be initiated because it would make the real size less than the size that is currently used.

User response

Determine the used size of the volume copy, and resubmit the command using a -rsize parameter value that is greater than or equal to the used size.

CMMVC6343E	The virtual disk (VDisk) copy was not shrunk because its real size can not be negative.
-------------------	--

Explanation

You are attempting to reduce the real size that is allocated to a thin-provisioned volume copy, but the command cannot be initiated because it would make the real size less than zero.

User response

Determine the real size of the volume copy, and resubmit the command using a supported -rsize parameter value.

CMMVC6344E	The repair operation cannot start because the virtual disk (VDisk) copy is already being repaired.
-------------------	---

Explanation

You are attempting to repair a thin-provisioned or compressed volume copy, but the copy is already being repaired.

User response

Specify the correct volume and copy parameters, and resubmit the command.

CMMVC6345E	The repair operation cannot start because the virtual disk (VDisk)
-------------------	---

copy was created using -import but the cluster could not recognize its format.

Explanation

You are attempting to repair a thin-provisioned or compressed volume copy that is reporting corrupt metadata. The cluster cannot repair the volume copy because it was not recognized as a valid thin-provisioned or compressed volume when it was imported into this cluster. The most probable cause is that the wrong MDisk was used when the volume copy was imported.

User response

Delete the volume copy, and resubmit the import operation using the same MDisk that was exported from the original cluster.

CMMVC6346E The repair operation cannot start because the space-efficient virtual disk (VDisk) copy was created using -import with a real size that is too small.

Explanation

You are attempting to repair a thin-provisioned volume copy that is reporting corrupt metadata. The cluster cannot repair the volume copy because although it was recognized as a valid thin-provisioned volume when it was imported into this cluster, the real size allocated to the volume copy is too small. The most probable cause is that the incorrect value was supplied with -rsize parameter when the volume copy was imported.

User response

Delete the volume copy. Resubmit the import operation either using a larger value for -rsize, or supplying the -rsize parameter without a value to let the system choose a real size.

CMMVC6347E The specific update package cannot be installed on this hardware level.

Explanation

The version of software that you are attempting to install does not support the hardware level of the configuration node.

User response

Check the release notes for the version of software that you want to install. Ensure that the version of

software that you install supports the hardware level of all of the nodes in the cluster, and resubmit the task.

CMMVC6348E The command failed as there was not enough information provided to process successfully.

Explanation

You have submitted a task with a combination of parameters and parameter values that does not provide the minimum amount of required information.

User response

Ensure that you specify a supported combination of parameters and parameter values, and resubmit the task.

CMMVC6349E The command was not initiated because the VDisk cache has been lost and you have not specified the -force option.

Explanation

You must specify the -force option when you move a volume from one I/O group to another and the volume has lost cache data.

User response

Resubmit the command and specify the -force option.

CMMVC6350E The command failed because there is insufficient mirror bitmap space.

Explanation

The command failed because there is insufficient free memory to allocate the bitmap that is needed for volume mirroring or formatting in the I/O group. Mirroring bitmaps are temporarily used for the formatting of non-mirrored volumes and for tracking the synchronization of mirrored volumes.

User response

Complete one of the following actions:

- Submit a **chiogrp** command to increase the bitmap space.
- Remove volume mirrors from the I/O group.
- Create the volume with formatting turned off.

Resubmit the command that caused this error.

CMMVC6351E The command failed because the virtual disk (VDisk) is not mirrored.

Explanation

Only mirrored volumes are supported for this command.

User response

Perform one of the following actions:

- Submit the appropriate command for a volume that is not mirrored.
- Submit a addvdiskcopy command to add a copy to the volume, and resubmit the command that caused this error.

CMMVC6352E The command failed because the number of copies of this virtual disk (VDisk) would exceed the limit.

Explanation

You cannot exceed the limit on the number of copies that are supported for a volume.

User response

Submit a rmvdiskcopy or splitvdiskcopy command to decrease the number of volume copies, and resubmit the command that caused this error.

CMMVC6353E The command failed because the copy specified does not exist.

Explanation

You must specify an existing copy for this command.

User response

Submit an lsvdiskcopy command to show all of the available copies for this volume. Select a copy that exists, and then resubmit the command that caused this error.

CMMVC6354E The command failed because a copy is not synchronized.

Explanation

The copy that you specify for this command must be a synchronized copy.

User response

Use the lsvdiskcopy command to view the synchronization status. Wait for the copy to

synchronize. If you want the synchronization process to complete more quickly, increase the rate by submitting a chvdisk command. When the copy is synchronized, resubmit the command that caused this error.

CMMVC6355E The command failed because an image mode copy is not synchronized.

Explanation

An attempt was made to remove an image mode copy, and the data on the copy is not synchronized with the host-accessible copy.

User response

Wait for the volume copy to resynchronize, then retry the command. Alternatively, specify the - **discardimage** or the - **force** parameter to force the delete operation.

CMMVC6356E The command failed because a copy is not synchronized and -force was not specified.

Explanation

When you specify a copy for this command, the copy must be synchronized unless you also specify the -force parameter.

User response

Perform one of the following actions:

- Use the lsvdiskcopy command to view the synchronization status. Wait for the copy to synchronize. If you want the synchronization process to complete more quickly, increase the rate by submitting a chvdisk command. When the copy is synchronized, resubmit the command that caused this error.
- Resubmit the command and specify the -force parameter.

Note: When you specify the -force parameter with the command that caused this error, the entire volume copy is resynchronized.

CMMVC6357E The command failed because the copy specified is not synchronized and -force was not specified.

Explanation

When you specify a copy for this command, the copy must be synchronized unless you also specify the -force parameter.

User response

Perform one of the following actions:

- Use the `lsvdisksyncprogress` command to view the synchronization status. Wait for the copy to synchronize. If you want the synchronization process to complete more quickly, increase the rate by submitting a `chvdisk` command. When the copy is synchronized, resubmit the command that caused this error.
- Resubmit the command and specify the `-force` parameter.

Note: When you specify the `-force` parameter with the command that caused this error, the created volume is no longer guaranteed to have identical data to the original volume when the split is performed.

CMMVC6358E The command failed because the copy specified is the only synchronized copy.

Explanation

The command failed because the copy specified is the only synchronized copy.

User response

Use the `lsvdisksyncprogress` command to view the synchronization status. Wait for another copy to synchronize. If you want the synchronization process to complete more quickly, increase the rate by submitting a `chvdisk` command. When the copy has synchronized, resubmit the command that caused this error.

CMMVC6359E The command failed because there are insufficient online synchronized copies.

Explanation

This error occurs when at least one of the volume copies is offline.

User response

Fix all of the errors that are associated with the volume copies, and resubmit the command.

CMMVC6363E The command failed because the Logical Block Address (LBA) specified is invalid for this virtual disk (VDisk).

Explanation

You must specify a Logical Block Address (LBA) that is a valid address for this volume.

User response

Use the `lsvdisk` command to obtain the volume size, and resubmit the command that caused this error using a logical block address that is in range.

CMMVC6364E The command failed because the logical block address (LBA) requested is too large for the disk.

Explanation

You have specified an LBA in conjunction with a volume or MDisk, but the LBA is too large and does not exist on the disk.

User response

Check the size of the disk, and resubmit the command using an LBA that exists on the disk.

CMMVC6365E The command timed out.

Explanation

The command has not completed in a reasonable amount of time. Processing of the command required the software to wait for a set of MDisk reads or writes to complete, and the predefined reasonable wait time has been exceeded.

User response

Resolve any MDisk or fabric event log entries, and resubmit the command.

CMMVC6366E One or more nodes in the cluster has hardware that is not supported by the new code.

Explanation

The version of code that you are attempting to install does not support the hardware in at least one node in the cluster.

User response

Check the release notes for the version of code that you want to install. update hardware so that all of the hardware in the cluster is supported by the new version of code, and resubmit the task.

CMMVC6367E A remote cluster is running software that is incompatible with the new software package.

Explanation

The version of software that you are attempting to install on the local cluster does not support the version of software that is installed on the remote cluster.

User response

Check the release notes for the version of software that you want to install. Perform one of the following actions:

- update the software on the remote cluster to a version that is supported by the version of software that you want to install on the local cluster before you update the software on the local cluster.
- Delete the cluster partnership to stop all remote copy relationships between the clusters, and resubmit the task.

CMMVC6368E	The new code might be incompatible with the remote cluster.
-------------------	--

Explanation

The version compatibility between clusters cannot be checked because the remote cluster is not accessible.

User response

Perform one of the following actions:

- Ensure that the link to the remote cluster is functioning properly, and resubmit the task.
- Delete the cluster partnership to stop all remote copy relationships between the clusters, and resubmit the task.

CMMVC6369W	The FlashCopy storage capacity that the cluster is using is approaching the FlashCopy storage capacity that is licensed.
-------------------	---

Explanation

You are being warned that the FlashCopy storage capacity license might be exceeded soon.

User response

update the FlashCopy storage capacity license to prevent recurrence of this warning message.

CMMVC6370W	The Remote Copy storage capacity that the cluster is using is approaching the Remote Copy storage capacity that is licensed.
-------------------	---

Explanation

You are being warned that the Remote Copy storage capacity license might be exceeded soon.

User response

update the Remote Copy storage capacity license to prevent recurrence of this warning message.

CMMVC6372W	The virtualized storage capacity that the cluster is using is approaching the virtualized storage capacity that is licensed.
-------------------	---

Explanation

You are being warned that the virtualized storage capacity license might be exceeded soon.

User response

update the virtualized storage capacity license to prevent recurrence of this warning message.

CMMVC6373W	The virtualized storage capacity that the cluster is using exceeds the virtualized storage capacity that is licensed.
-------------------	--

Explanation

You are being warned that the virtualized storage capacity license has been exceeded.

User response

Update the virtualized storage capacity license to prevent recurrence of this warning message.

CMMVC6374W	The FlashCopy storage capacity that the cluster is using exceeds the FlashCopy storage capacity that is licensed.
-------------------	--

Explanation

You are being warned that the FlashCopy storage capacity license has been exceeded.

User response

update the FlashCopy storage capacity license to prevent recurrence of this warning message.

CMMVC6375W	The Remote Copy storage capacity that the cluster is using exceeds the Remote Copy storage capacity that is licensed.
-------------------	--

Explanation

You are being warned that the Remote Copy storage capacity license has been exceeded.

User response

update the Remote Copy storage capacity license to prevent recurrence of this warning message.

CMMVC6394E The command failed because an attempt to make the virtual disk cache empty took too long.

Explanation

The failed command must empty the volume cache before attempting the requested action to ensure that data is preserved. The empty volume cache subtask has taken too long, and therefore the command that you have submitted was not initiated so that other configuration activity can occur.

The system continues attempting to empty the volume cache.

The storage associated with the volume is probably overloaded.

User response

Wait a few minutes to allow the volume cache to empty. Resubmit the command.

Alternatively, you can use the -force parameter, if the command supports the -force parameter, to bypass the empty volume cache subtask. However, specifying the -force parameter will discard cache data for the volume. Only use the -force flag with this command if you do not intend to use the existing contents of the volume.

In addition to the above actions, investigate the performance of the network storage devices associated with this volume. The performance of host applications using these devices might be degraded.

Remedial action to resolve a performance problem enables host application performance to return to optimal conditions, and prevents this error message from recurring when you resubmit the command that caused this error.

CMMVC6399E The command failed because there is not enough memory available for reservation.

Explanation

At least one node in the cluster cannot reserve the required amount of memory. This might be caused by pinned data in the cache.

User response

Check for events in the event log. Follow the fix procedures to resolve the problem.

CMMVC6400E The command failed because a specified managed disk (MDisk) is already in use.

Explanation

You cannot specify an MDisk for this command if it is already in a storage pool or is being used as an image mode volume.

User response

Specify an MDisk that is not being used as an image mode volume and is not in a storage pool, and resubmit the command.

CMMVC6401E The command failed because one or more of the specified managed disks (MDisks) that you have specified are not in the required managed disk group.

Explanation

The command requires that all of the MDisks that you specify must be in the same storage pool.

User response

Ensure that all of the MDisks that you specify are in the same storage pool, and resubmit the command.

CMMVC6402E The command failed because the managed disk (MDisk) is not in the required managed disk group.

Explanation

All of the MDisks that you specify must be in the required storage pool. At least one of the source MDisks that you have specified in the command is not in the required storage pool.

User response

Ensure that all of the MDisks that you specify are in the storage pool that you specify, and resubmit the command.

CMMVC6403E The command failed because the target managed disk (MDisk) is not in the required managed disk group.

Explanation

All of the MDiskS that you specify must be in the required storage pool. At least one of the target MDiskS that you have specified in the command is not in the required storage pool.

User response

Ensure that all of the MDiskS that you specify are in the storage pool that you specify, and resubmit the command.

CMMVC6404E	The command failed because the source and target managed disk groups must be different.
-------------------	--

Explanation

The source and target storage pools that you specify for a cross storage pool migration must be different.

User response

Ensure that the source and target storage pools that you specify for a cross storage pool migration are different, and resubmit the command.

CMMVC6405E	The command failed because the target copy was not specified.
-------------------	--

Explanation

A target copy must be specified when you use migrations on a volume and more than one volume copy exists.

User response

Specify the target copy, and resubmit the command.

CMMVC6406E	The command failed because the specified managed disk group does not exist.
-------------------	--

Explanation

At least one of the storage pools that you have specified in the parameter list does not exist.

User response

Ensure that each of the storage pools that you specify exists, and resubmit the command.

CMMVC6407E	The command failed because the managed disk group is invalid.
-------------------	--

Explanation

At least one storage pool ID is above the maximum value that is available for the system.

User response

Ensure that each storage pool ID that you specify in the parameter list exists, and resubmit the command.

CMMVC6408E	The command failed because too few managed disk groups were specified.
-------------------	---

Explanation

You must specify the number of storage pools that is consistent with the other parameters and parameter values that you specify with the command.

User response

Refer to the command documentation for valid combinations of parameters and parameter values. Use a valid combination of parameters and values, and resubmit the command.

CMMVC6409E	The command failed because too many managed disk groups were specified.
-------------------	--

Explanation

You must specify the number of storage pools that is consistent with the other parameters and parameter values that you specify with the command.

User response

Refer to the command documentation for valid combinations of parameters and parameter values. Use a valid combination of parameters and values, and resubmit the command.

CMMVC6410E	The command failed because too few managed disks (MDiskS) were specified.
-------------------	--

Explanation

You must specify the number of MDiskS that is consistent with the other parameters and parameter values that you specify with the command.

User response

Refer to the command documentation for valid combinations of parameters and parameter values. Use a valid combination of parameters and values, and resubmit the command.

CMMVC6411E	The command failed because too many managed disks (MDiskS) were specified.
-------------------	---

Explanation

You must specify the number of MDisk that is consistent with the other parameters and parameter values that you specify with the command.

User response

Refer to the command documentation for valid combinations of parameters and parameter values. Use a valid combination of parameters and values, and resubmit the command.

CMMVC6412E	The command failed because the managed disk group extent size is above maximum permitted size.
-------------------	---

Explanation

You cannot specify a storage pools extent size that is larger the maximum size.

User response

Specify a storage pool extent size that is less than or equal to the maximum size, and resubmit the command.

CMMVC6413E	The command failed because the managed disk (MDisk) is invalid.
-------------------	--

Explanation

At least one MDisk ID is above the maximum value that is available for the system.

User response

Ensure that each MDisk ID that you specify in the parameter list exists, and resubmit the command.

CMMVC6414E	The command failed because the managed disk (MDisk) is currently being migrated.
-------------------	---

Explanation

When you submit this command, you cannot specify an MDisk that is being migrated.

User response

Either wait until the migration has completed for the MDisk that you specify, or specify a different MDisk, and resubmit the command.

CMMVC6415E	The command failed because the managed disk group warning threshold is too low.
-------------------	--

Explanation

You must specify a storage pool warning threshold that is equal to or greater than the minimum size.

User response

Specify a storage pool warning threshold that is equal to or greater than the minimum size, and resubmit the command.

CMMVC6416E	The command failed because the managed disk group warning threshold is too high.
-------------------	---

Explanation

You must specify a storage pool warning threshold size that is equal to or less than the size of the storage pool when all of the MDisk have been added, or you must specify a storage pool warning percentage that is equal to or less than the maximum warning threshold percentage.

User response

Specify valid values for the storage pool warning threshold size or percentage, and resubmit the command.

CMMVC6417E	The command failed because the managed disk group warning threshold is invalid.
-------------------	--

Explanation

To specify the warning threshold there must be at least one managed MDisk in the storage pool.

User response

Ensure that there is at least one MDisk defined for the storage pool or remove the warning threshold, and resubmit the command.

CMMVC6418E	The command failed because the virtual disk (VDisk) is in the process of being resized.
-------------------	--

Explanation

When you submit this command, you cannot specify a volume that is being resized.

User response

Wait for the resize volume operation to complete. If you still want to submit this command after the operation has completed, resubmit the command.

CMMVC6419E **The command failed because one or more of the specified managed disks (MDisks) are in the process of being deleted.**

Explanation

When you submit this command, you cannot specify an MDisk that is being deleted with the -force option.

User response

Wait for the delete MDisk operation to complete. Do not include any MDisk that have been deleted in the list of MDisk that you specify, and resubmit the command.

CMMVC6421E **The specified size exceeds the maximum permitted for this feature.**

Explanation

- A **chiogrp** command was attempted where the maximum bitmap memory for one or more functions was exceeded. The maximum supported amount of bitmap memory for the RAID function, the Volume Mirroring function and the Metro Mirror or Global Mirror Copy Services functions is 512 MB. The maximum supported amount of bitmap memory for the FlashCopy® function is 2048 MB.
- Alternatively, a remote copy was attempted that used a memory size of 512 MB when the value of the **remote_copy_free_memory** variable reached 0. This scenario is unlikely.

User response

Retry the command, specifying a smaller amount of memory where necessary.

CMMVC6422E **The specified size is too big. Total size of memory across all features exceeds maximum permitted.**

Explanation

- The maximum combined amount of memory across all functions other than FlashCopy® is 552 MB. A **chiogrp** command was used to change the memory allocations for an I/O group where the specified -**size** value (which defaults to units of megabytes) caused the total memory to exceed the maximum.
- Alternatively, an attempt was made to create a large HyperSwap volume, but enough memory was not available to complete the request.

User response

Review the amount of memory that is used by each feature by running an **lsiogrp** command that specifies the name or ID of an I/O group. Run one or more **chiogrp** commands to redistribute the amount of memory that each feature uses without exceeding the maximum. For more information, run the **help chiogrp** command.

CMMVC6423E **The Send Inventory email operation failed because email is not started.**

Explanation

The send inventory email functionality has been enabled but the email service has not been started.

User response

Disable the send inventory email functionality or start the email service.

CMMVC6424E **The Send Inventory email operation failed because there are no inventory email users.**

Explanation

The send inventory functionality has been enabled but no email users with the ability to receive inventory emails have been created.

User response

Either turn off the send inventory email functionality or create an email user account that is capable of receiving inventory emails. Refer to the documentation for the mke-mailuser command for help on creating email users.

CMMVC6425E **The action failed because the maximum number of objects has been reached.**

Explanation

The action failed because the maximum number of objects has been reached.

User response

Check the object specified in the command and determine if you need to specify a different object. Make the correction and resubmit the command.

CMMVC6426E **The command failed because a specified managed disk (MDisk) is already in use.**

Explanation

You cannot specify an MDisk that is already configured as an image mode volume.

User response

Specify an unmanaged disk, and resubmit the task.

CMMVC6427E	The command failed because one or more of the specified managed disks (MDisks) are not in the required managed disk group.
-------------------	---

Explanation

The create volume task requires that all of the MDisks that you specify must be in the same storage pool.

User response

Ensure that all of the MDisks that you specify are in the same storage pool, and resubmit the task.

CMMVC6428E	The command failed because the source managed disk (MDisk) is not in the required managed disk group.
-------------------	--

Explanation

The task requires that all of the source MDisks that you specify must be in the same storage pool.

User response

Ensure that all of the source MDisks that you specify are in the same storage pool, and resubmit the task.

CMMVC6429E	The command failed because the target managed disk (MDisk) is not in the required managed disk group.
-------------------	--

Explanation

The task requires that all of the target MDisks that you specify must be in the same storage pool.

User response

Ensure that all of the target MDisks that you specify are in the same storage pool, and resubmit the task.

CMMVC6430E	The command failed because the target and source managed disk groups must be different.
-------------------	--

Explanation

The cross storage pool migration task does not support specifying the same storage pool to be both the source and target storage pool.

User response

Specify a source storage pool and a target storage pool that are not identical, and resubmit the task.

CMMVC6431E	The command failed because the target copy was not specified.
-------------------	--

Explanation

When you use migrations on a volume and there is more than one copy, you must specify which copy to use as the target copy.

User response

Specify the target copy, and resubmit the task.

CMMVC6432E	The command failed because the specified managed disk group does not exist.
-------------------	--

Explanation

All of the storage pools that you specify must already exist.

User response

Ensure that all of the storage pools that you specify already exist, and resubmit the task.

CMMVC6433E	The command failed because the managed disk group is invalid.
-------------------	--

Explanation

All of the storage pool IDs that you specify must have a value that is less than or equal to the maximum supported storage pool ID value.

User response

Ensure that all storage pools have supported ID values. Ensure that all of the storage pools that you specify already exist, and resubmit the task.

CMMVC6434E	The command failed because too few managed disk groups were specified.
-------------------	---

Explanation

The combination of parameters and parameter values that you have specified is not supported. The task

requires that you specify more storage pools than the number that you have specified.

User response

Specify a supported combination of parameters and parameter values, and resubmit the task.

CMMVC6435E	The command failed because too many managed disk groups were specified.
-------------------	--

Explanation

The combination of parameters and parameter values that you have specified is not supported. The task requires that you specify fewer storage pools than the number that you have specified.

User response

Specify a supported combination of parameters and parameter values, and resubmit the task.

CMMVC6436E	The command failed because too few managed disks (MDisks) were specified.
-------------------	--

Explanation

The combination of parameters and parameter values that you have specified is not supported. The task requires that you specify more MDisks than the number that you have specified.

User response

Specify a supported combination of parameters and parameter values, and resubmit the task.

CMMVC6437E	The command failed because too many managed disks (MDisks) were specified.
-------------------	---

Explanation

The combination of parameters and parameter values that you have specified is not supported. The task requires that you specify fewer MDisks than the number that you have specified.

User response

Specify a supported combination of parameters and parameter values, and resubmit the task.

CMMVC6438E	The command failed because the managed disk group extent size is above maximum permitted size.
-------------------	---

Explanation

The storage pool extent size that you have specified is greater than the supported maximum value.

User response

Specify a supported storage pool extent size, and resubmit the task.

CMMVC6439E	The command failed because the managed disk (MDisk) is invalid.
-------------------	--

Explanation

Each MDisk ID must have a value that is less than or equal to the maximum supported MDisk ID value.

User response

Ensure that all of the MDisks have supported ID values. Ensure that all of the MDisks that you specify already exist, and resubmit the task.

CMMVC6440E	The command failed because the managed disk (MDisk) is currently being migrated.
-------------------	---

Explanation

When you submit this task, you cannot specify an MDisk that is being migrated.

User response

Ensure that the MDisk that you specify is not migrating, and resubmit the task. If you want to specify the same MDisk and resubmit the task, ensure that the migration for that MDisk has completed before you resubmit the task.

CMMVC6441E	The command failed because the managed disk group warning threshold is too low.
-------------------	--

Explanation

The value that you have specified for the storage pool warning threshold is less than the minimum supported value.

User response

Specify a supported value for the storage pool warning threshold, and resubmit the task.

CMMVC6442E	The command failed because the managed disk group warning threshold is too high.
-------------------	---

Explanation

Either the value for the storage pool warning percentage is greater than the maximum supported value, or the storage pool warning disk size is greater than the storage pool capacity.

User response

Specify supported values for storage pool warning percentage and disk size, and resubmit the task.

CMMVC6443E	The command failed because the managed disk group warning threshold is invalid.
-------------------	--

Explanation

If you submit this command and specify a storage pool warning threshold percentage, you must specify a storage pool that contains at least one MDisk and you must specify a supported value for the storage pool warning threshold percentage.

User response

Either do not specify a storage pool warning threshold percentage, or specify a supported value for the storage pool warning threshold percentage and specify a storage pool that contains at least one MDisk, and resubmit the task.

CMMVC6444E	The command failed because the virtual disk (VDisk) is in the process of being resized.
-------------------	--

Explanation

You cannot specify a volume that is being resized when you submit this task.

User response

Wait for the resize volume task to complete. You can specify the same volume and resubmit this task only after the resize volume task that is in progress has completed.

CMMVC6445E	The command failed because one or more of the specified managed disks (MDisks) are in the process of being deleted.
-------------------	--

Explanation

You cannot specify an MDisk that is being force deleted.

User response

Wait until all force delete MDisk tasks have completed. Ensure that all of the MDisks that you specify still exist, and resubmit the task.

CMMVC6446E	The command failed because the managed disk groups have different extent sizes.
-------------------	--

Explanation

This task requires that the extent size of the source storage pool and the extent size of the target storage pool must be identical.

User response

If you want to resubmit this command, ensure that the source and target storage pools have the same extent size. If you want to move a volume to a storage pool that has a different extent size, you must use the procedure that is documented in the technical notes.

CMMVC6447E	The command failed because the virtual disk (VDisk) is currently being migrated.
-------------------	---

Explanation

You cannot specify a volume that is being migrated.

User response

Either wait until the volume migration process has completed and resubmit the task, or specify a volume that is not being migrated and resubmit the task.

CMMVC6448E	Deleting this node will cause data loss for resources associated with the I/O group of this node.
-------------------	--

Explanation

This node contains resources which are vital to the I/O group and unavailable elsewhere. Removing this node will cause a loss of customer data.

It is recommended that this node not be removed unless the customer data supported by it is of no consequence.

User response

The -force option must be used to remove this node.

CMMVC6449E	The operation was not performed because the partnership owns Global or Metro Mirror relationships or consistency groups.
-------------------	---

Explanation

The cluster partnership cannot be removed while there are Global or Metro Mirror relationships or consistency groups that are configured in the local cluster and that are associated with the remote cluster of the partnership.

User response

Identify all of the Global or Metro Mirror relationships or consistency groups in the local cluster that are configured between this cluster and the remote cluster of the partnership. Remove all of the relationships and groups that you have identified, and resubmit the task.

Note: Do not remove relationships or groups that are associated with a different cluster, and do not remove relationships or groups that are contained entirely within the local cluster.

CMMVC6450W A FlashCopy mapping was created but physical_flash is not enabled.

Explanation

The create FlashCopy mapping task has succeeded. However, physical_flash should be enabled when you create a FlashCopy mapping in the physical disk license scheme.

User response

Ensure that you have the appropriate virtualization license for the cluster configuration that you want to enable. Ensure that the license settings for this cluster match the license.

Delete the FlashCopy mapping or enable physical_flash.

CMMVC6451W A Global Mirror or Metro Mirror relationship was created but physical_remote is not enabled.

Explanation

The create Global Mirror or Metro Mirror relationship task has succeeded. However, physical_remote should be enabled when you create a Global Mirror or Metro Mirror relationship and the cluster uses the physical disk license scheme.

User response

Ensure that you have the appropriate virtualization license for the cluster configuration that you want to enable. Ensure that the license settings for this cluster match the license.

Delete the Global Mirror or Metro Mirror relationship or enable physical_remote.

CMMVC6452W You are using the physical disk license scheme but the values for physical_flash and physical_remote are not set.

Explanation

The task has succeeded. However, you should enable physical_flash before you create a FlashCopy mapping and you should enable physical_remote before you create a Global Mirror or Metro Mirror mapping.

User response

Enable physical_flash before you create a FlashCopy mapping. Enable physical_remote before you create a Global Mirror or Metro Mirror relationship.

CMMVC6453W You have disabled the physical disk license scheme but the capacity license scheme is not set.

Explanation

The task has succeeded. However, you should configure a license scheme before you create a FlashCopy, Global Mirror or Metro Mirror relationship. You can configure a physical disk license scheme or a capacity license scheme, but not both.

User response

If you do not have a virtualization feature license that is valid for this cluster, contact your IBM sales representative and obtain a license. Ensure that the license settings for this cluster match the license that you have for this cluster.

CMMVC6454E The command failed because the physical disk license scheme is not enabled.

Explanation

You can only enable physical_flash or physical_remote when the physical disk license scheme is enabled.

User response

Ensure that you have the appropriate virtualization license for the cluster configuration that you want to enable. Ensure that the license settings for this cluster match the license. Resubmit the task if it supported by the license.

CMMVC6455E The command failed because a capacity license scheme parameter was specified but the

physical disk license scheme is enabled.

Explanation

You cannot enable the capacity license scheme or specify a capacity license scheme parameter while the cluster is using the physical disk license scheme.

User response

Ensure that you have the appropriate virtualization license for the cluster configuration that you want to enable. Ensure that the license settings for this cluster match the license. Resubmit the task if it supported by the license.

CMMVC6456E The command failed because a physical disk license scheme parameter was specified but the capacity license scheme is enabled.

Explanation

You cannot enable the physical disk license scheme or specify a physical disk license scheme parameter while the cluster is using the capacity license scheme.

User response

Ensure that you have the appropriate virtualization license for the cluster configuration that you want to enable. Ensure that the license settings for this cluster match the license. Resubmit the task if it supported by the license.

CMMVC6457E One or more quorum disks are on the specified controller.

Explanation

You cannot disable the setting that allows a controller to support a quorum disk while a quorum disk is configured on the controller.

User response

Move all quorum disks from the controller to a different storage system using the setquorum command, and resubmit this task.

CMMVC6458E The specified controller cannot support quorum disks.

Explanation

The controller type of the controller that you specified does not support quorum disks.

User response

Specify a controller that has a controller type that supports quorum disks, and resubmit the task.

CMMVC6459E The mkrcrelationship command failed because the same VDisk was specified as the master and auxiliary VDisk.

Explanation

A relationship cannot be created from a volume to itself. The mkrcrelationship command requires that you specify two different volumes for the master and auxiliary positions. These can be two volumes in the local cluster, or a volume in each of two different clusters.

User response

Specify a master volume and an auxiliary volume that are not identical to each other, and resubmit the task.

CMMVC6460E The command failed because the migration source is offline.

Explanation

The source of the migration is offline. The offline source is either an image mode MDisk or the entire storage pool.

User response

- If you submitted the rmmddisk command and specified a regular MDisk, determine the storage pool to which the source MDisk is defined, and follow the procedure for bringing the storage pool online. There will be an entry in the event log for the corresponding storage pool.
- If you submitted the rmmddisk command and specified an image mode MDisk, determine the source MDisk and follow the procedure for bringing the image mode MDisk online. There will be an entry in the event log for the corresponding MDisk.
- If you submitted a command to migrate a copy of an image mode volume, determine the corresponding source MDisk and follow the procedure for diagnosing problems with MDisk. There will be an entry in the event log for the corresponding MDisk.
- If you submitted any other command to migrate a volume copy, determine the storage pool to which the volume is defined, and follow the procedure for bringing the storage pool online. There will be an entry in the event log for the corresponding storage pool.

CMMVC6461E **The command failed because starting the migration will result in VDisks going offline in the source managed disk group.**

Explanation

A migration from an image mode volume will use the source storage pool and the source storage pool assumes the combined state of the image mode MDisk and the storage pool. If the online or offline states of the image mode MDisk and the storage pool are different on different nodes, the source volume might go offline or all of the volumes in the source storage pool might go offline.

User response

For each node, note the online or offline states of the source volume and the source storage pool. If one entity is online and the other is offline, bring online whichever is offline. Taking the online entity offline is not recommended because other volumes might go offline.

CMMVC6462E **The command failed because starting the migration will result in VDisks going offline because the target managed disk group is offline.**

Explanation

The migration process assigns the volume an online or offline state based on the states of the source and target storage pools. In this case, based on the offline state of the target storage pool the volume that is currently online would have been taken offline. The command cannot be initiated because this action is not supported. There will be an entry in the event log for the corresponding storage pool.

User response

For each node, note the online or offline state of the source and target storage pools. For each node, if one of these two storage pools is online and the other is offline, bring online whichever storage pool is offline. Taking the online storage pool offline is not recommended because other volumes might go offline.

CMMVC6463E **The command failed because Starting the migration will result in VDisks going offline because a target MDisk is offline.**

Explanation

The volume is currently online. The migration process assigns the volume an online or offline state based on the states of the source and target MDisks. In this case, based on the offline state of the target MDisk, the volume would have been taken offline. The task cannot be initiated because this action is not supported.

User response

Bring the target MDisk online by following the recommended procedure for bringing an MDisk online, and resubmit the command.

CMMVC6464E **The Create FlashCopy mapping task cannot be initiated because the size of the source VDisk is being changed by a previously submitted task.**

Explanation

You cannot submit this task while the Change volume size task is in progress.

User response

Wait until the Change volume size task completes, and then resubmit the task.

CMMVC6465E **The Create FlashCopy mapping task cannot be initiated because the size of the target VDisk is being changed by a previously submitted task.**

Explanation

You cannot submit this task while the Change volume size task is in progress.

User response

Wait until the Change volume size task completes, and then resubmit the task.

CMMVC6466E **The Create FlashCopy mapping task cannot be initiated because an identical map already exists.**

Explanation

A map between the source and target volumes that you have specified is defined. You cannot define a map that is exactly the same as a map that is already defined.

User response

Specify a unique map when you submit this task.

CMMVC6467E **The Create FlashCopy mapping task cannot be initiated because a FlashCopy map with the same target VDisk already exists in the consistency group.**

Explanation

You cannot create more than one FlashCopy map with the same target volume in the same consistency group.

User response

Specify a target volume for the FlashCopy map that is unique to the consistency group when you submit this task.

CMMVC6468E **The Start or Prepare FlashCopy mapping task cannot be initiated because the target volume is the source of a different FlashCopy map that is being restored.**

Explanation

You cannot start or prepare a map while the target of the map is the source volume of another FlashCopy mapping that is being restored.

User response

Ensure that the target volume in the map that you are attempting to start or prepare is not the source volume of another FlashCopy mapping that is being restored when you submit the task. You could stop the associated map that is being restored, or you could wait for the map that is being restored to reach the Idle_or_Copied state.

CMMVC6469E **The Split stop FlashCopy map task cannot be initiated because the mapping is either being restored or is not in the copy complete state.**

Explanation

You cannot split stop a FlashCopy map while it is being restored or is not in the copy complete state.

User response

Ensure that the map is not being restored and is in the copy complete state when you submit this task.

CMMVC6470E **The Start or Prepare FlashCopy mapping task cannot be initiated because the target VDisk is being used by a different FlashCopy map.**

Explanation

You cannot start or prepare a map while the target of the map is also the target volume of another map that is in one of the following states: copying, stopping, suspended, prepared or preparing.

User response

Ensure that the target volume in the map that you are attempting to start or prepare is not the target volume of another FlashCopy mapping that is in one of the unsupported states when you submit this task.

CMMVC6471E **The Create cluster partnership task cannot be initiated because a cluster in the existing partnership has a downlevel code version that does not support this configuration.**

Explanation

One scenario in which this error occurs is when a cluster at a higher version is partnered to a cluster at a lower version that does not support multiple cluster mirroring, and you attempt to create another partnership to a cluster at the higher version to implement multiple cluster mirroring. Adding a partnership to a third cluster is not supported while at least one cluster in the current partnership is at the lower version.

User response

Either update the downlevel cluster software version to a version that supports this task or remove the partnership to the cluster that has the downlevel software version, and resubmit the task.

CMMVC6472E **The Create cluster partnership task cannot be initiated because the remote cluster with which you are attempting to create a partnership has a downlevel code version that does not support this configuration.**

Explanation

The code versions of the clusters in the existing partnership do not support a partnership with a cluster that has the code version of the remote cluster with which you are attempting to create a partnership. If a

cluster at version 5.1.0 or later is already in a partnership with another cluster at version 5.1.0 or later, you can only add a partnership to a cluster at version 5.1.0 or later, and cannot add a partnership to a cluster at version 4.3.1 or earlier. If a cluster at version 5.1.0 or later is already in a partnership with another cluster at version 4.3.1 or earlier, you cannot add another partnership while the partnership with the cluster at version 4.3.1 exists. If a cluster is not in a partnership, you can create a partnership between it and a cluster at any version. One scenario in which this error occurs is when you attempt to add a partnership with a remote cluster at version 4.3.1 or earlier to a cluster at version 5.1.0 or later that is already in partnership with another cluster at version 5.1.0 or later.

User response

Either update the downlevel cluster code version to a version that supports this task or remove all existing partnerships from the cluster to which you want to partner the cluster that has the downlevel version, and resubmit the task.

CMMVC6473E The partnership task cannot be initiated because the supported maximum number of accessible remote clusters would be exceeded.

Explanation

With multiple cluster mirroring, you can build a configuration of a chain of clusters. There is a limit to the number of clusters that you can configure in the chain. The task would have resulted in exceeding the supported maximum number of clusters in a chain.

User response

Ensure that the resulting configuration is supported when you submit this task.

CMMVC6474E The Create partnership task cannot be initiated because there is a Global Mirror or Metro Mirror relationship or consistency group that has a deleted partnership.

Explanation

You must resolve the unpartnered objects error that is related to the deleted partnership with a Global Mirror or Metro Mirror relationship or consistency group before you can create a partnership from the local cluster to more than one other cluster.

User response

Resolve the unpartnered objects error, and resubmit the task. To resolve the error, either delete the unpartnered Global Mirror or Metro Mirror relationship or consistency group from the deleted partnership, or create a partnership for the unpartnered objects.

CMMVC6475E The Add relationship to group task cannot be initiated because the master cluster of the relationship that you are attempting to add to the group is the auxiliary cluster of the group, and the auxiliary cluster of the relationship that you are attempting to add to the group is the master cluster of the group.

Explanation

All of the relationships within a group must have the same master cluster as the group and must have the same auxiliary cluster as the group. The determination as to which cluster is assigned as the master cluster when you create a relationship or consistency group is based on the cluster from which you submit the task.

User response

- Perform one of the following three options:
- Delete the group and create the group so that the master cluster of the group is identical to the master cluster of the relationship and the auxiliary cluster of the group is identical to the auxiliary cluster of the relationship.
 - Delete the relationship and create the relationship so that the master cluster of the relationship is identical to the master cluster of the group and the auxiliary cluster of the relationship is identical to the auxiliary cluster of the group.
 - Specify a group and a relationship that have identical master clusters and identical auxiliary clusters.

Resubmit the task.

CMMVC6478E The Enable remote authentication service task cannot be initiated because the server settings are not configured.

Explanation

You cannot enable the remote authentication service until the server has been configured with all of the required settings. You must specify the user name, password, and remote authentication server URL, and if required, the SSL certificate.

User response

Ensure that the server settings are configured correctly, and resubmit the task.

CMMVC6479E The task cannot be initiated because the user group table is full.

Explanation

The maximum supported number of user groups is already configured in the user group table.

User response

Delete a user group that is not required from the table, and resubmit the task.

CMMVC6480E The task cannot be initiated because the user group that you have specified is not defined.

Explanation

You must specify a user group that exists in the user group table.

User response

Either create the user group that you had specified or specify an existing user group, and resubmit the task.

CMMVC6481E The Modify user group task cannot be initiated because you have specified a default user group.

Explanation

Examples of default user groups are SecurityAdmin, Administrator, CopyOperator, Service, and Monitor.

User response

Specify a user group that is not a default user group when you submit this task.

CMMVC6482E The Delete user group task cannot be initiated because you have specified a default user group.

Explanation

Examples of default user groups are SecurityAdmin, Administrator, CopyOperator, Service, and Monitor.

User response

Specify a user group that is not a default user group when you submit this task.

CMMVC6483E The task cannot be initiated because the user group name that you have specified already exists.

Explanation

Each user group must have a unique name.

User response

If you want to define a new user group with the name that you had specified, you must first delete the existing user group that has that same name. Specify a user group name that does not exist when you submit this task.

CMMVC6484E The task cannot be initiated because the role that you have specified is not supported.

Explanation

Examples of valid roles are SecurityAdmin, Administrator, CopyOperator, Service, and Monitor.

User response

Specify a supported role, and resubmit the task.

CMMVC6485E The Delete user group task has failed because there is at least one user that is defined as a member of the group, and you did not specify the -force parameter.

Explanation

You cannot delete a user group that is not empty unless you specify the -force parameter. If you use the -force parameter when you delete a user group, all of the users that were in the deleted user group are added to the Monitor user group.

User response

Ensure that you specify the correct user group. For each member of the specified user group that you want to belong to a user group other than Monitor, move that member to the desired group. If the user group has at least one member, specify the -force parameter when you submit the task.

CMMVC6486E The task cannot be initiated because the user table is full.

Explanation

The maximum supported number of users is already configured in the user table.

User response

Delete a user that is not required from the table, and resubmit the task.

CMMVC6487E **The task cannot be initiated because the user name that you have specified already exists.**

Explanation

Each user must have a unique name.

User response

If you want to define a new user with the name that you had specified, you must first delete the existing user that has that same name. Specify a user name that does not exist when you submit this task.

CMMVC6488E **The task cannot be initiated because you have specified a user group ID that is not correct.**

Explanation

You must specify a valid user group ID when you submit this task.

User response

Specify a valid user group ID, and resubmit the task.

CMMVC6489E **The task cannot be initiated because you have specified more than one password.**

Explanation

This task allows you to specify only one password.

User response

Specify only one password, and resubmit the task.

CMMVC6490E **The task cannot be initiated because you have specified both a user group and the use of the remote authentication service.**

Explanation

You cannot specify a user group when you specify the use of the remote authentication service.

User response

Either specify a user group or specify the use of the remote authentication service, but not both, and resubmit the task.

CMMVC6491E **The task cannot be initiated because an SSH key and password were not specified for the remote authentication service.**

Explanation:

An SSH key and password are required for the remote authentication service.

User response

Specify a valid SSH key and password when issuing this task.

CMMVC6492E **The task cannot be initiated because you have specified a local user but you have not specified a user group.**

Explanation

You must specify a user group when you specify a local user for this task.

User response

Specify a valid user group if you specify a local user when you submit this task.

CMMVC6493E **The task cannot be initiated because the user that you have specified is not defined.**

Explanation

You must specify a user that exists in the user table.

User response

Either create the user that you had specified or specify an existing user, and resubmit the task.

CMMVC6494E **The task cannot be initiated because you cannot remove a default user.**

Explanation

Examples of default users are SecurityAdmin, Administrator, CopyOperator, Service, and Monitor.

User response

Specify a user that is not a default user when you submit this task.

CMMVC6495E **The task cannot be initiated because the user superuser must be a local user.**

Explanation

You cannot define the user superuser to use the remote authentication service.

User response

Ensure that you have specified the correct user, and resubmit the task.

CMMVC6496E The task cannot be initiated because you cannot remove the superuser password.

Explanation

The user superuser must always have a password defined.

User response

Ensure that you have specified the correct user when you submit the task.

CMMVC6497E The task cannot be initiated because the user that you have specified does not have a password defined.

Explanation

You cannot remove a password that does not exist.

User response

Ensure that you have specified the correct user when you submit the task.

CMMVC6498E The task cannot be initiated because the user that you have specified does not have an SSH key defined.

Explanation

You cannot remove an SSH key that does not exist.

User response

Ensure that you have specified the correct user when you submit the task.

CMMVC6499E The task has failed because the SSH key that you have specified is already defined for another user.

Explanation

A single SSH key cannot be defined for more than one user.

User response

Either specify a unique SSH key for the user that you had specified or delete the user that has the SSH key that you had specified, and resubmit the task.

CMMVC6500E The action failed because the source and destination virtual disks (VDisks) are the same.

Explanation

The action failed because the source and destination volumes are the same.

User response

Recheck your command and make the correction to the source or destination or both that you have specified. Then resubmit the command after you have made the correction.

CMMVC6501E The action failed because the node hardware is incompatible with the current I/O group member.

Explanation

The action failed because the node hardware is incompatible with the current I/O group member.

User response

Recheck your command for the specified I/O group and verify that it is correct. Make the correction and resubmit the command. If your original command is correct, do further research to correct this problem.

CMMVC6502E The FlashCopy mapping was not prepared because preparing consistency group 0 is not a valid operation.

Explanation

The FlashCopy mapping was not prepared because preparing consistency group 0 is not a valid operation.

User response

Recheck your command and ensure that you specified the correct consistency group. Make the correction and resubmit the command. If you specified the correct consistency group, then more research is necessary to correct this problem.

CMMVC6503E The FlashCopy mapping or consistency group was not stopped because stopping consistency group 0 is not a valid operation.

Explanation

The FlashCopy mapping or consistency group was not stopped because stopping consistency group 0 is not a valid operation.

User response

Recheck your command to ensure that you specified the FlashCopy mapping or consistency group that you intended. Make the correction and resubmit the command. If the command was correct, more research is needed before you can resubmit the command.

CMMVC6504E	The task cannot be initiated because the SSH key file that you have specified does not contain a valid SSH key.
-------------------	--

Explanation

You must specify an SSH key file that contains a valid SSH key.

User response

Specify an SSH key file that contains a valid SSH key, and resubmit the task.

CMMVC6505E	The task has failed because an error has occurred while communicating with the authentication service.
-------------------	---

Explanation

The cluster is configured to use an authentication service to control which users are authorized to access the cluster. An error has occurred while the cluster was attempting to contact the authentication service. The error is probably the result of an incorrect configuration, either of the cluster or of the authentication service. This error occurs if the SSL certificate, user name or password is incorrect.

User response

Ensure that the authentication service is functioning properly. Ensure that the cluster authentication service configuration is correct. Resubmit the task.

CMMVC6506E	The task has failed because a timeout has occurred while communicating with the authentication service.
-------------------	--

Explanation

The cluster is configured to use an authentication service to control which users are authorized to access

the cluster. A timeout has occurred while the cluster was attempting to contact the authentication service. This timeout is probably the result of a TCP/IP network problem or of an incorrect configuration. Configuring the incorrect IP address or protocol in the authentication service URL causes this error. The protocol can be either http or https.

User response

Ensure that the cluster authentication service configuration is correct. Ensure that the Ethernet network between the cluster and the authentication service is functioning properly. Ensure that the authentication service is functioning properly. Resubmit the task.

CMMVC6507E	The task has failed because the authentication service reports an incorrect user name or password.
-------------------	---

Explanation

The cluster is configured to use an authentication service to control which users are authorized to access the cluster.

If the password for the user name has recently been changed on the authentication service, you might be required to force the cluster to refresh its authentication cache. You can force the refresh using the cluster console View Cluster Properties, Remote Authentication panel or by submitting the Command-Line Interface command `chauthservice -refresh`.

User response

Ensure that the user name and password that you use is correct.

If the password for the user name has recently been changed on the authentication service, force the cluster to refresh its authentication cache.

If the user name that you are using also has a password configured on the cluster, ensure that the password that is configured on the cluster is identical to the password that is configured for that user name on the authentication service.

Resubmit the task.

CMMVC6508E	The task has failed because the authentication service reports that the authentication token has expired.
-------------------	--

Explanation

The cluster is configured to use an authentication service to control which users are authorized to access

the cluster. The authentication token, which is saved as a browser cookie, has expired. You can modify the token expiration property that is set by the authentication service to reduce the frequency of this error in the future.

User response

Either acquire a new authentication token or log in with a user name and password, and resubmit the task.

CMMVC6510E	The task has failed because the user name or password is not correct.
-------------------	--

Explanation

The password that you are using does not match the password that is configured on the cluster for the user name that you are using.

User response

Enter the correct user name or password, and resubmit the task.

CMMVC6511E	The task has failed because the cluster is not configured correctly to use the authentication service.
-------------------	---

Explanation

The user name that you are using is configured to be authenticated using an authentication service, but either the cluster is not configured to use an authentication service or the function is not enabled.

User response

If you want to use an authentication service, configure the cluster to use the service.

If you do not want to use an authentication service, modify the configuration of the user name on the cluster to remove the designation for the use of the authentication service.

Resubmit the task.

CMMVC6512E	The task has failed because you cannot both create a new quorum disk and set that new disk to active using the same command.
-------------------	---

Explanation

The create new quorum disk task and set disk to active task must be done using two separate tasks.

User response

Submit a create new quorum disk task. When that task has completed, submit a task to activate the new disk.

CMMVC6513E	The task has failed because you cannot activate a quorum disk until all of the quorum disks have been initialized.
-------------------	---

Explanation

The initialization process for at least one disk has not yet completed. You cannot select a disk as the active disk until the initialize process for all of the quorum disks has completed.

User response

Wait until the initialize quorum disk process has completed for all of the quorum disks, and resubmit the task.

CMMVC6514E	The task has failed because the disk that you have selected to activate is not online.
-------------------	---

Explanation

A disk must be online to be eligible for activation.

User response

Either bring the disk that you have selected online or select a different disk that is already online, and resubmit the task.

CMMVC6515E	The task has failed because at least one quorum disk is in the Excluded state.
-------------------	---

Explanation

You cannot activate a quorum disk when one or more of the quorum disks are in the Excluded state.

User response

Either create additional quorum disks or change the configuration so that none of the quorum disks is in the Excluded state. Ensure that none of the quorum disks are in the Excluded state, and resubmit the task.

CMMVC6516E	The command has failed because an IPv4 cluster address cannot be removed while remote IPv4 services are configured.
-------------------	--

Explanation

The configured management IP address protocols determine whether IPv4 or IPv6 or both are enabled on the cluster. If a cluster does not have an IPv4 cluster address the IPv4 protocol stack will not be enabled, and therefore remote services such as email servers or SNMP servers cannot be accessed through an IPv4 address.

User response

If you can only access the service through an IPv4 address and you need to continue to use the service, you will also have to continue to specify an IPv4 cluster address even if you do not intend to manage your cluster through this address.

Otherwise, re-configure the cluster so that all remote services use only IPv6 addresses, and resubmit the task to remove the IPv4 cluster address.

CMMVC6517E	The command has failed because an IPv6 cluster address cannot be removed while remote IPv6 services are configured.
-------------------	--

Explanation

The configured management IP address protocols determine whether IPv4 or IPv6 or both are enabled on the cluster. If a cluster does not have an IPv6 cluster address the IPv6 protocol stack will not be enabled, and therefore remote services such as email servers or SNMP servers cannot be accessed through an IPv6 address.

User response

If you can only access the service through an IPv6 address and you need to continue to use the service, you will also have to continue to specify an IPv6 cluster address even if you do not intend to manage your cluster through this address.

Otherwise, re-configure the cluster so that all remote services use only IPv4 addresses, and resubmit the task to remove the IPv6 cluster address.

CMMVC6518E	The task has failed because no roles are defined for the current user on the cluster.
-------------------	--

Explanation

The cluster has been configured to use an authentication service to control which users are authorized to access the cluster. The user's credentials were accepted by the authentication service, but none of the groups defined for the user on

the authentication service match any of the user groups that are defined on the cluster.

User response

Perform the following steps in sequence:

1. Determine which user groups are defined for the user on the authentication service.
2. Ensure that at least one user group that is defined for the user on the authentication service is also defined on the cluster.
3. Ensure that at least one user group that is defined for the user on both the authentication service and the cluster has its 'remote' parameter set to 'enabled'.
4. Resubmit the task.

CMMVC6519E	The task has failed because you cannot change the user group of the 'superuser' account to anything other than 'SecurityAdmin'.
-------------------	--

Explanation

The user group that is assigned to the user name 'superuser' must always be 'SecurityAdmin'. This assignment cannot be changed.

User response

Ensure that you specify a user account other than 'superuser' if you submit a task to change the user group of a user account from 'SecurityAdmin' to a different user group.

CMMVC6520E	You cannot use this task to modify the properties of the current user because those properties are only defined by an authentication service.
-------------------	--

Explanation

The current user is not defined on the cluster. The current user is defined on an authentication service, and the cluster is configured to use that authentication service. You must use the authentication service to change the current user's password.

If you want to enable command-line interface (CLI) access to the cluster by using an SSH key, you must define the current user on the cluster and associate the SSH key with that user. If you also want to continue using the authentication service for the current user, you must enable the 'remote' setting for the new current user account that you create on the cluster.

User response

If you want to change your password, use the authentication service for that task.

If you want to enable command-line interface (CLI) access to the cluster by using an SSH key, define your user account on the cluster and associate the ssh key with that definition. If you also want to continue using the authentication service to authorize your user account, enable the 'remote' setting for your newly created user account on the cluster.

CMMVC6521E The task cannot be initiated because it would have resulted in a user account definition for a local user that specifies neither a password nor an SSH key.

Explanation

The definition of a local user must always specify either a password or an SSH key.

User response

When you submit this task, ensure that you have specified the correct user account and parameters, and that all local user definitions would still specify either a password or an SSH key after the task completes.

CMMVC6522E Authorization has failed.

Explanation

An SSH login attempt has failed. This message will be followed by a second message that will contain detailed information about the cause of the error.

User response

Follow the instructions in the second error message to solve the problem.

CMMVC6523E The URL that you have entered is not valid.

Explanation

The URL must start with either http:// or https:// and must use only the following characters: A-Z, a-z, 0-9, - _ : [] . ~ / %.

User response

Ensure that the URL that you enter starts with one of the supported strings and contains only supported characters, and resubmit the task.

CMMVC6524E The name that you have entered is not valid. The name cannot begin

or end with a space character, and the name cannot contain any of the following characters: * : , \ ' %

Explanation

A space cannot be the first or last character in the name that you enter. Also, the following characters are not supported anywhere in the name: * : , \ ' %

User response

Ensure that the name that you enter does not begin or end with the space character and that it does not contain any of the unsupported characters listed above, and resubmit the task.

CMMVC6525E The password that you have entered is not valid. The password cannot begin or end with a space character.

Explanation

A space cannot be the first or last character in the password that you enter.

User response

Ensure that the password that you enter does not begin or end with the space character, and resubmit the task.

CMMVC6526E The Create VDisk task cannot be initiated because the number of copies that you have requested is not equal to the number of unique MDisk groups that you have specified.

Explanation

When you submit this task, you must specify a unique storage pool for each volume copy that you request.

User response

Specify the same number of unique storage pools as the number of volume copies that you request, and resubmit the task.

CMMVC6527E The name that you have entered is not valid. The name can contain letters, numbers, spaces, periods, dashes, and underscores. The name must begin with a letter or an underscore. The name must not begin or end with a space.

Explanation

A number or space cannot be the first character and a space cannot be the last character in the name that you enter. Also, the following characters are not supported anywhere in the name: * : , " ' % #

User response

Ensure that the name you enter does not begin with a number, does not begin or end with a space character, and does not contain any of the unsupported characters listed above, and resubmit the task.

CMMVC6528E The command cannot be initiated because the MDisk mode is not set to Array.

Explanation

Any MDisk that you specify for this command must be a local MDisk that is an array of LDisks. The mode of the MDisk that you have specified is not Array.

User response

Either select a different MDisk that is a local MDisk and is an array of LDisks, or configure the system so that the MDisk that you have specified is a local MDisk and is an array of LDisks, and resubmit the command.

CMMVC6529E The command cannot be initiated because the maximum supported number of MDisks already exists.

Explanation

This command requires that an MDisk is available for array creation. There are no available MDisks for array creation because the maximum number of MDisks is already configured on the cluster.

User response

Ensure that a local MDisk is available, and resubmit the command. To make a local MDisk available for this task, either delete an array on an existing local MDisk or remove a SAN attached MDisk and configure a local MDisk.

Some other considerations to fix this error:

- Each distributed array occupies 16 slots, starting at an mdisk id divisible by 16, therefore you might also consider the need to delete 16 unwanted mdisks starting on a mdiskid boundary divisible by 16. If you need additional information see lsmdisk.
- Or, you can delete an unwanted distributed array to make space for a distributed array.

- You must also issue the detectmdisk command to ensure that the mdisk inventory is updated after deleting mdisks.

CMMVC6530E The command cannot be initiated because the maximum supported number of arrays already exists.

Explanation

The cluster already has the maximum number of arrays that it can support. The command attempted to add a new array.

User response

Remove an array that is no longer needed, and resubmit the command.

CMMVC6532E The command cannot be initiated because there is insufficient free memory that is available to the I/O group.

Explanation

This command requires that there is sufficient free memory available for the specified I/O group to allocate the memory that is required for the new array.

User response

Ensure that there is sufficient memory available to the I/O group, and resubmit the command. You can increase the amount of memory that is allocated to the I/O group. You can also reduce the amount of memory that is used by reducing the number volume mirrors or Copy Services relationships in the I/O group.

CMMVC6533E The command cannot be initiated because the specified array member does not exist in the selected array.

Explanation

This command requires that the array member that you specify is an LDisk. It is possible that the array member that you specified was an LDisk that was recently deconfigured due to an error. You can use the lsarraymember command to display the available members of an array.

User response

Select an array member that has an associated LDisk, and resubmit the command.

CMMVC6534E The command cannot be initiated because the drive that you have specified does not exist.

Explanation

You have specified a drive ID that is not defined.

User response

Use the `lsdrive` command to display existing drive IDs. Specify only existing drive IDs, and resubmit the command.

CMMVC6535E	The command cannot be initiated because you have specified an incorrect number of drives to configure an array using the RAID geometry that you have specified.
-------------------	--

Explanation

Each RAID geometry requires a minimum number of available drives in order to configure an array using that geometry. For example, a RAID 6 geometry requires that you specify at least four available drives. The number of drives that you have specified is less than the minimum number of drives that are required for the RAID geometry that you have specified.

User response

Ensure that you specify a sufficient number of drives to accommodate the RAID geometry that you specify, and resubmit the command. You might want to specify a different number of drives or a different RAID geometry.

CMMVC6536E	The command cannot be initiated because you have specified more drives than the specified RAID geometry permits.
-------------------	---

Explanation

The number of drives that you specify must be within the supported range of number of drives that is supported for the RAID geometry that you specify. For example, a RAID 1 geometry requires that you specify exactly two available drives.

User response

Specify a number of available drives that is supported for the RAID geometry that you specify, and resubmit the command.

CMMVC6537E	The command cannot be initiated because the drive that you have specified has a Use property that is not supported for the task.
-------------------	---

Explanation

The command cannot be run because the current use value of a drive that was specified in the command prevents the command from being applicable.

User response

Refer to the command documentation to determine what drive use values are supported by this command. You can use the `lsdrive` command to find the current use value of a drive. Select a drive that has a supported use value when you submit this command.

CMMVC6538E	The command cannot be initiated because at least one of the drives that you have specified has a Use property that is not Candidate.
-------------------	---

Explanation

Every drive that you specify for this command must have a Use property of Candidate. You can submit the `lsdrive` command to display the Use property of existing drives.

User response

Ensure that all of the drives that you specify have a Use property of Candidate, and resubmit the command.

CMMVC6539E	The command cannot be initiated because the array does not have sufficient redundancy.
-------------------	---

Explanation

The array must have sufficient redundancy when you submit this command. The task that you have requested would have taken the array offline.

User response

Fix all errors that are related to the array that you have specified and restore redundancy to the array before you resubmit the command.

CMMVC6540E	The task cannot be initiated because the thin-provisioned grain size is too small to accommodate the provisioned capacity that you have requested for the volume.
-------------------	--

Explanation

The provisioned capacity that you requested requires a larger number of grains than the supported maximum for the specified grain size.

User response

Either increase the grain size, decrease the requested provisioned capacity of the volume, or both, and then resubmit the task.

CMMVC6541E The task cannot be initiated because the provisioned capacity that you have requested for the volume is larger than the maximum capacity that is supported for the extent size.

Explanation

The extent size of the storage pool that you selected would require a larger number of extents than the supported maximum to accommodate the provisioned capacity that you requested for the volume.

User response

Either select a different storage pool that has an extent size that is large enough to accommodate the requested provisioned capacity or specify a provisioned capacity that is supported for the extent size of the storage pool that you selected, and resubmit the task.

CMMVC6542E The remote authentication task has failed.

Explanation

An error has occurred while attempting to authenticate a user account using a remote authentication service. You can run the svc_snap task to gather cluster information that can be used in problem determination.

User response

Contact IBM technical support for assistance.

CMMVC6543E The task cannot be initiated because you can only specify a direct-attached managed drive when you submit the task.

Explanation

The drive that you have specified either is not managed or is not a local drive.

User response

Specify a direct-attached MDisk when you submit this task.

CMMVC6544E The task cannot be initiated at this time because the direct-attached

managed drive that you have specified is too busy. Resubmit the task when the drive is less busy.

Explanation

The task takes approximately thirty seconds to complete. When the direct-attached managed drive is busy, the time that is required to complete the task increases. When the drive is too busy, the task cannot complete in a reasonable amount of time.

User response

Resubmit the task when the direct-attached managed drive is less busy.

CMMVC6545E The Apply Drive Software task has failed to access the software download image.

Explanation

Either the image file cannot be read, the validation signature is incorrect, the drive type or software type is not correct, or the image file is corrupted.

User response

Reinstall the software download image, and resubmit the task. If the problem persists, contact IBM technical support for assistance.

CMMVC6546E A drive error was detected during the Apply Drive Software task.

Explanation

At least one of the drives that was requested for update by the Apply Drive Software task has failed.

User response

Either remove the failed drives from the list of drives for the Apply Drive Software task and resubmit the task, or perform problem determination on the failed drives.

CMMVC6547W The Download FPGA firmware task has been initiated. The MDisk remains Offline while the task is in progress. Do not remove power from the drive or node while the task is in progress.

Explanation

The task might take approximately fifteen minutes to complete. When the task completes, the drive status changes to Online automatically.

User response

Ensure that electrical power is continuously being supplied to the node and the drive, at least until the task completes and the drive status changes to Online.

CMMVC6548E The FPGA firmware cannot be applied because the drive has a use other than candidate.

Explanation

Updating a drive FPGA level is not guaranteed to maintain data integrity, therefore the drive must not be part of an array. To ensure this, the drive must have a use of "candidate" before the package can be applied.

User response

If the drive is currently in the "failed" state, run through all maintenance actions required for the drive before continuing. If the drive is a spare or is unused, the drive use can be changed through the GUI or through the **chdrive** command. If a drive is currently part of an array, a hot-spare drive must be configured and the drive use changed to "failed" before changing the use to "candidate".

CMMVC6549E The Authentication task has failed because the authentication service URL that you have specified is not a valid URL.

Explanation

This error might be caused by the authentication service not operating correctly or by an incorrect URL being defined for the authentication service. You can use the **chauthservice** command to change the URL that is defined in the cluster for the authentication service.

User response

Ensure that the authentication service is operating correctly. Ensure that the authentication service URL that is defined in the cluster is correct, and resubmit the task.

CMMVC6550E The Authentication task has failed because the network address that is specified in the authentication service URL cannot be resolved.

Explanation

The authentication service URL that is defined in the cluster has a network address that cannot be resolved. You can use the **chauthservice** command to change the URL that is defined in the cluster for the authentication service.

1966 Spectrum Virtualize for SAN Volume Controller, FlashSystem, and Storwize Family: Command-Line Interface User's Guide

User response

Ensure that the authentication service is operating correctly. Ensure that the authentication service URL that is defined in the cluster is correct. Ensure that the network connection between the cluster and the authentication service is operating correctly, and resubmit the task.

CMMVC6551E The Authentication task has failed because the combination of user name and password that is defined in the cluster for authorization by the authentication service is not defined on the authentication service.

Explanation

The authentication service has refused an authentication request from the cluster. You can use the **chauthservice** command to change the user name or the password that is defined in the cluster for the authentication service.

User response

Ensure that the user name and password combination that is defined in the cluster for the authentication service is also defined on the authentication service, and resubmit the task.

CMMVC6552E The Authentication task has failed because an SSL connection could not be established with the authentication service.

Explanation

This error might be caused by an incorrect SSL configuration on the authentication service server or by a rejection by the authentication service server of the SSL certificate that is configured on the cluster. You can use the **chauthservice** command to set the SSL certificate that is defined in the cluster for the authentication service server.

User response

Ensure that the SSL configuration on the authentication service server is correct and that the SSL certificate that is defined in the cluster for the authentication service server is correct, and resubmit the task.

CMMVC6553E The task cannot be initiated because at least one quorum disk is not in the correct state.

Explanation

All of the quorum disks must have a state of Online when you set an MDisk to be the active quorum disk.

User response

Ensure that all of the quorum disks have a state of Online, and resubmit the task.

CMMVC6554E	The Authentication task has failed because the user name that was received from the authentication service is not a valid cluster user name.
-------------------	---

Explanation

The cluster user name cannot exceed 256 characters in length, and cannot contain any of the following characters:

- colon :
- percent sign %
- comma ,
- double quote ""
- single quote '

User response

Change the definition of the user name in the remote authentication service so that it conforms to the cluster user name requirements, and resubmit the task.

CMMVC6555E	The Authentication task has failed because the authentication service either sent an incorrect response, or it sent a response that indicates that the authentication request has failed for a reason other than incorrect authentication credentials.
-------------------	---

Explanation

Either the format of the response from the authentication service is not valid or the response indicates a failure to authenticate that is not related to the credentials that were being authenticated.

User response

Ensure that the authentication service is functioning correctly, and resubmit the task. If the problem persists, contact the authentication service technical support for assistance.

CMMVC6556E	The task cannot be initiated because an error has occurred while attempting to read a file.
-------------------	--

Explanation

The task specified the name of a file on the file system of the cluster configuration node. The specified file cannot be opened. This error might be caused by a typographical error in the file name that you specified or by a failover of the configuration node to a different node than the node into which you are currently logged in.

User response

Ensure that the file has been copied to the current configuration node and that you are logged in to that node, specify the correct file name, and resubmit the task.

CMMVC6557E	The task cannot be initiated because the file that you have specified is too large.
-------------------	--

Explanation

The task specified the name of a file on the file system of the cluster configuration node. The specified file cannot be used because it exceeds the maximum size supported for the task. If the file has been corrupted, you can copy the correct version of the file onto the configuration node to restore the correct file size. The maximum file size is described in the task help.

User response

Specify the correct file name and ensure that the size of the file does not exceed the supported maximum file size for this task, and resubmit the task.

CMMVC6558E	The command cannot be initiated because it might cause VDisks to go Offline. Refer to the cluster Command-Line Interface (CLI) command help for this command.
-------------------	--

Explanation

You are being warned that this command might result in taking volumes Offline. After you completely understand the possible consequences by reading the command help, you can override the safety precautions and avoid this message by using the -force flag.

User response

1. Submit the `lsnode dependantvdisks` command to determine which volumes will go Offline if you resubmit this command using the `-force` flag. If you received this message when you submitted the `applysoftware` command, you must submit the `lsnode dependantvdisks` command for every node in the cluster; for all other commands you must submit the `lsnode dependantvdisks` command for the node that you specified as a parameter in the command that generated this message.
2. This step is required because it is critically important that you understand the implications of using the `-force` flag for the specific command that you have submitted: Refer to the CLI command help to determine what safety precautions are bypassed when you use the `-force` flag. The ignored precautions differ, depending on the command.
3. If you want to bypass the safety precautions when you resubmit the command, you must use the `-force` flag.

CMMVC6559E The Add or Change email user command has failed because you have specified a user type of 'support' and you have specified either the -warning or -info parameter value as 'on'.

Explanation

The user type 'support' is intended to be used to indicate that the user is from a hardware maintenance support service external to your organization. Therefore, only events with the more serious notification type of 'error' can be sent to a 'support' user type.

User response

Ensure that you have specified the correct user type. If you want this user to receive warning or information notifications, do not specify the `-usertype support` parameter and value. If you specify the user type as 'support', you must specify the `-warning` and `-info` parameters as 'off'.

CMMVC6560E The command has failed because the specified IP address is already in use by the cluster.

Explanation

You cannot specify an IP address that is already configured to be used by the cluster.

User response

Ensure that the IP address that you specify is not already configured for use by the cluster, and resubmit the task.

CMMVC6561E The set quorum active task has failed because either another set quorum active task is in progress or the selected disk cannot be set as the active quorum disk.

Explanation

This is a multi-step task and can take from a few seconds to several minutes to complete. Only one set quorum active task can be in progress at any specified time. This error has one of two causes. Either another set quorum task is already in progress, or the internal cluster logic did not accept your request to make the selected disk the active quorum disk.

User response

Check the state of the MDisk and complete any outstanding fix procedures. If another set quorum active task might be in progress, wait for several minutes for that task to complete, and resubmit this task. If you have received this error when there is no other set quorum active task in progress, specify a different disk to replace the current active quorum disk and specify the same quorum index number, and resubmit this task.

CMMVC6562E The requested size exceeds the maximum supported value.

Explanation

You have submitted a command that has a size parameter and an associated unit option that has a default value of Megabytes (MB, 2e20 bytes) when the `-unit` option is not specified. The value that you have specified for the size parameter in combination with the specified or default unit value is greater than the maximum supported size of (2e64 - 1) bytes.

User response

Ensure that the size that you specify is correct for the value of the unit option that is defaulted or specified, and that the size is not greater than the maximum supported size, and resubmit the task.

CMMVC6563E The command has failed because a user that you have specified is not configured to receive email notifications.

Explanation

All of the users that you specify as a target recipient in the **testemail** command must already have at least one of the following email notification flags set to 'on': -error, -warning, or -info.

User response

Ensure that all of the users that you specify have at least one email notification flag set to 'on', and resubmit the command.

CMMVC6564E **You cannot make this user a remote user because the password type is not valid for a remote user.**

Explanation

The remote authentication server has requirements that do not accept legacy type passwords. This user has a legacy type password.

User response

Either specify a new password and resubmit the command, or first modify the password and then resubmit the command to designate remote authentication for this user.

CMMVC6565E **The command has failed because the specified node is not online.**

Explanation

The command requires that the status of the node that you specify is Online.

User response

Ensure that the node that you specify has a status of Online when you submit this command.

CMMVC6566E **The command cannot be submitted because specifying the -failover parameter requires that you also specify either the -name, -iscsialias or -noiscsialias parameter.**

Explanation

You have not specified the required failover data that is required when you specify the -failover parameter.

User response

Ensure that you want to specify the -failover parameter. When you specify the -failover parameter

with this command, ensure that you also specify either the -name, -iscsialias or -noiscsialias parameter.

CMMVC6567E **The Apply Drive Software task cannot be initiated because no download images were found in the package file.**

Explanation

The drive software update package file was unpacked but no download software images were found in the package.

User response

Acquire a valid flash drive software update package file, and resubmit the task using the new package file.

CMMVC6568E **The Apply Drive Software task cannot be initiated because for at least one of the specified drives, the specified file does not contain an image for that drive's technology.**

Explanation

The package file documentation lists the drive types for which there are images.

User response

Acquire a valid drive software update package file that contains an image for this drive type, and resubmit the task using the new package file.

CMMVC6569E **The Apply Drive Software task has failed because no download images were found in the package file of this software type.**

Explanation

The package file documentation lists the drive types and software types for which there are images. The value of the -type parameter that you enter for software type is case-sensitive.

User response

Ensure that the value that you enter for the -type parameter exactly matches the software type that is contained in the flash drive software update package file, and resubmit the command.

CMMVC6570E **The command was not initiated because the cache mode of the virtual disk (VDisk) is already in the state that you had requested.**

Explanation

You have issued a change volume cache mode command but requested the current mode, so there would not have been a change. Therefore, the command was ignored.

User response

List the volume properties to determine the current cache mode. If you want to change the cache mode, ensure that you specify a cache mode that is different from the current cache mode, and resubmit the command.

CMMVC6571E	The command has failed because the I/O group that manages the virtual disk (VDisk) that you specified was offline when you submitted the command. You can use the -force flag to force the operation, which might result in the loss of cache data.
-------------------	--

Explanation

If you submit this command without the -force flag, the I/O group that manages the volume that you specify must have a state of Online.

Note: Use of the -force flag when you change the cache mode might result in loss of the cache data for the volume, depending on the current cache mode and requested cache mode. One example of a risk of potential loss of cache data would be changing the cache mode from readwrite to none.

User response

Either follow service procedures to bring the I/O group online or specify the -force flag to force the change of the cache mode of the volume, and resubmit the task.

CMMVC6572E	The command has failed because the I/O group that manages the virtual disk (VDisk) that you specified is not stable.
-------------------	---

Explanation

The unstable I/O group condition is typically transient, and usually occurs during I/O group failover or fail back processing.

User response

Wait a few minutes, and resubmit the command.

CMMVC6573E	The command has failed because the VDisk that you specified is a source or target of a FlashCopy
-------------------	---

mapping that is in the prepared state.

Explanation

If the volume is the source or target of a FlashCopy mapping, the FlashCopy mapping must be in the idle_copied state or the stopped state when you change the cache mode of the volume.

User response

Either remove or stop the FlashCopy mapping and wait for the FlashCopy mapping state to become idle_copied or stopped, and resubmit the command.

CMMVC6574E	The command has failed because the VDisk that you specified is a source or target of a FlashCopy mapping that is in the suspended state.
-------------------	---

Explanation

If the volume is the source or target of a FlashCopy mapping, the FlashCopy mapping must be in the idle_copied state or the stopped state when you change the cache mode of the volume.

User response

Either remove or stop the FlashCopy mapping and wait for the FlashCopy mapping state to become idle_copied or stopped, and resubmit the command.

CMMVC6575E	The command has failed because the VDisk that you specified is a source or target of a FlashCopy mapping that is in the preparing state.
-------------------	---

Explanation

If the volume is the source or target of a FlashCopy mapping, the FlashCopy mapping must be in the idle_copied state or the stopped state when you change the cache mode of the volume.

User response

Either remove or stop the FlashCopy mapping and wait for the FlashCopy mapping state to become idle_copied or stopped, and resubmit the command.

CMMVC6576E	The command has failed because the VDisk that you specified is a source or target of a FlashCopy mapping that is in the stopping state.
-------------------	--

Explanation

If the volume is the source or target of a FlashCopy mapping, the FlashCopy mapping must be in the idle_copied state or the stopped state when you change the cache mode of the volume.

User response

Either remove or stop the FlashCopy mapping and wait for the FlashCopy mapping state to become idle_copied or stopped, and resubmit the command.

CMMVC6577E	The command has failed because the VDisk that you specified is a source or target of a FlashCopy mapping that is in the copying state.
-------------------	---

Explanation

If the volume is the source or target of a FlashCopy mapping, the FlashCopy mapping must be in the idle_copied state or the stopped state when you change the cache mode of the volume.

User response

Either remove or stop the FlashCopy mapping and wait for the FlashCopy mapping state to become idle_copied or stopped, and resubmit the command.

CMMVC6578E	The command has failed because the iSCSI name is already assigned or is not valid.
-------------------	---

Explanation

The cluster does not support duplicate iSCSI names. A valid iSCSI name cannot contain a comma or leading or trailing spaces.

User response

Ensure that you specify a unique and valid iSCSI name, and resubmit the command.

CMMVC6579E	The command cannot be initiated because the cluster Ethernet port 1 must always be fully configured in either the IPv4 or IPv6 format.
-------------------	---

Explanation

This error can be caused by an attempt to delete the only address that is configured on the primary Ethernet port on the cluster.

User response

When you delete an IP address on the primary Ethernet port, ensure that the other supported IP format is already configured on that port.

CMMVC6580E	The command cannot be initiated because the iSCSI alias that you specified contained either leading or trailing space characters.
-------------------	--

Explanation

The space character cannot be the starting or ending character of an iSCSI alias name.

User response

Ensure that the iSCSI alias that you specify does not begin or end with a space character, and resubmit the command.

CMMVC6581E	The command has failed because the maximum number of allowed iSCSI qualified names (IQNs) has been reached, or the IQN is already assigned or is not valid.
-------------------	--

Explanation

IQNs cannot exceed the maximum number allowed, must not be duplicated, must not contain a comma, and must not contain leading or trailing spaces.

User response

If the number of IQNs is within the allowed maximum, ensure that you specify a unique and valid IQN, and resubmit the command.

CMMVC6582E	The task has failed because the host that you specified is not mapped to an I/O group.
-------------------	---

Explanation

You cannot add a port to a host until you map the host to at least one I/O group.

User response

Map the host to at least one I/O group, and then resubmit the command.

CMMVC6583E	The command has failed because the name that you specified contains a character that is not supported for a node or cluster name.
-------------------	--

Explanation

A node or cluster name cannot contain any of the following characters or ASCII hexadecimal values:

- 0000-001F ASCII control characters
- 0020-002C The space character !""# \$ % the ampersand character ' () * + ,
- 002F /
- 003B-0040 ; the 'less than' character = > ? @
- 005B-0060 [\] ^ _ `
- 007B-007F { | } ~ and the DEL character

User response

Specify a valid name, and resubmit the command.

CMMVC6584E	The command cannot be initiated because it would unconfigure the remote authentication service while the service is enabled.
-------------------	---

Explanation

You cannot unconfigure the remote authentication service while it is enabled.

User response

Ensure that the remote authentication service is not being used, disable the service, and resubmit the task.

CMMVC6585E	The command cannot be initiated because the array that you have specified has a geometry of RAID 0, which is not a redundant geometry.
-------------------	---

Explanation

The array that you specify for this command must have a redundant geometry, and RAID 0 is not a redundant geometry.

User response

Ensure that you specify an array that has a redundant geometry when you submit the command.

CMMVC6586E	The command cannot be initiated because the action would cause array data loss due to the unsynchronized state of the array.
-------------------	---

Explanation

To avoid data loss, this command is not permitted to process an array that is not synchronized.

User response

Use the `lsarraysyncprogress` command to ensure that the synchronization process completes for this array, and resubmit the task.

CMMVC6587E	The command did not complete because I/O for the array was not quiesced within the allotted time period.
-------------------	---

Explanation

All outstanding I/O for the array must complete before the configuration can be changed. The command has failed because there is still outstanding I/O to be processed for the array, and the maximum amount of time allotted to the command has expired.

User response

Resubmit the task.

CMMVC6588E	The command cannot be initiated because a drive that you have specified has a capacity that is smaller than the minimum capacity that is required for the array that you have specified.
-------------------	---

Explanation

You can use the `lsarraymembergoals` command to identify the capacity requirement for a member of the array that you specified.

User response

Specify a drive that has sufficient capacity for the array that you specify when you submit the command.

CMMVC6589E	The command was not initiated because the drive that you have specified does not sufficiently match the array member goals and you did not specify the -balanced parameter.
-------------------	--

Explanation

If you do not specify the -balanced parameter, the new drive must be an exact match for the array member goals when you exchange a new drive for an existing array member. The new drive that you have specified does not match the goals. If you want to use the drive that you specified to replace an existing member of the array that you specified, you must specify the -balanced parameter, which forces the array member goals to be changed to accommodate the new drive.

User response

Either select a different drive that matches the array member goals or specify the `-balanced` parameter to force a change in the array member goals to accommodate the new drive, and resubmit the command.

CMMVC6590E	The command cannot be initiated because you did not specify the <code>-allowdegraded</code> parameter and the associated array member has insufficient spare protection.
-------------------	---

Explanation

This command requires that spare drives are available to assume the function of array member drives that are removed from the array. The requirement can be bypassed by using the `-allowdegraded` parameter.

User response

Either configure sufficient additional spare drives or specify the `-allowdegraded` parameter, and resubmit the command.

CMMVC6591E	The command cannot be initiated because the specified sequence number does not match the sequence number of any errors in the error log.
-------------------	---

Explanation

The sequence number that is specified in the command must be identical to the sequence number of an event in the event log.

User response

Check the event log to verify the sequence number of the event that you want to specify, and resubmit the command using the correct sequence number.

CMMVC6592E	The command cannot be initiated because at least one parameter that was specified is not supported when submitting a command to view the details of an error log entry.
-------------------	--

Explanation

Filtering parameters such as `'-order severity'` or `'-status alert'` that are valid when listing multiple event log entries are not supported for the command to view the details of a single event log entry.

User response

Check the command syntax, and use supported syntax when you submit the command.

CMMVC6593E	The command cannot be initiated because the error log entry has a status that is not supported for the command.
-------------------	--

Explanation

Only events with a status of `'alert'` or `'message'` can be manually marked as fixed or unfixed. Events with a status of `'monitoring'` or `'expired'` are not required to be marked as fixed or unfixed.

User response

Check the event log to verify the sequence number of the event that you want to specify. Ensure that the event that you specify has a status that is supported for the command when you submit the command.

CMMVC6594E	The command cannot be initiated because a drive was specified twice in the drive list.
-------------------	---

Explanation

The drive list cannot contain any duplicate entries because the same drive cannot be a member of an array more than once.

User response

Ensure that the drive list that you specify does not contain any duplicate entries when you submit this task.

CMMVC6595E	The command cannot be initiated because a drive that you have specified has a technology type that is not supported for the command.
-------------------	---

Explanation

The command supports only certain drive technology types. You have specified at least one drive that has a technology type that is not supported for the command.

User response

Consult the command documentation to determine which drive technology types are supported for the command. Submit the `lsdrive` command to determine which drives are available. Specify an available drive that has a technology type that is supported for the command when you submit the command.

CMMVC6596E **The command has failed because you have specified an I/O group that does not exist.**

Explanation

You must specify an existing I/O group when you submit this command.

User response

Specify an existing I/O group, and resubmit the command.

CMMVC6597E **The command has failed because the email settings are not configured.**

Explanation

The cluster email system settings must be configured before you can submit a command for error notifications.

User response

Configure the cluster email system settings to enable error notifications and resubmit the command.

CMMVC6608E **The command cannot be initiated because Easy Tier is active on the virtual disk copy.**

Explanation

Easy Tier is active on the volume copy, which prevents the success of the command.

User response

Disable Easy Tier on the volume copy or on the storage pool in which the volume copy resides, and resubmit the command.

CMMVC6609E **The command cannot be initiated because the size of the Mdisk is smaller than the extent size of the MDisk group.**

Explanation

The sizing of the Mdisk in relation to the storage pool is not correct, which prevents the success of the command.

User response

Use a larger Mdisk or make the extent size of the storage pool smaller than the Mdisk, and resubmit the command.

CMMVC6610E **The update cannot start because one or more I/O groups are in maintenance mode.**

Explanation

Maintenance mode is used during system servicing, which prevents updates.

User response

Complete system servicing, turn off maintenance mode, and resubmit the command.

CMMVC6611E **The command has failed because the specified enclosure is offline.**

Explanation

The specified enclosure is offline, which has prevented the success of the command.

User response

Fix any errors associated with the specified enclosure, and resubmit the command.

CMMVC6612E **The command has failed because of a hardware error.**

Explanation

A hardware error has occurred, which has prevented the success of the command.

User response

Fix any errors in the specified object, and resubmit the command.

CMMVC6613E **The command has failed because the specified enclosure type is not supported.**

Explanation

You have attempted to use an enclosure of an unsupported type.

User response

Do not attempt to use the specified enclosure type.

CMMVC6614E **The command has failed because the specified canister is offline.**

Explanation

The specified canister is offline, which has prevented the success of the command.

User response

Fix any errors associated with the specified canister, and resubmit the command.

CMMVC6615E **The command cannot be initiated because nodes from this enclosure cannot be added to the specified I/O group, or another enclosure is in the process of being added.**

Explanation

The nodes in the enclosure being added are used elsewhere in the cluster, the target I/O group contains nodes of a different control enclosure, or another enclosure has not yet completed the process of being added.

User response

If a node already exists in the I/O group, add nodes from the same enclosure only. If the I/O group is empty, you can use a different control enclosure in which the nodes are not in a cluster. If you are currently adding another enclosure, wait for the completion of that process. Ensure that both nodes of an added enclosure are online and that the enclosure is listed in the output of the `lsenclosure` command.

CMMVC6616E **All available quorum disks are dependent on the MDisks that you have specified.**

Explanation

The list of MDisks that you have specified contains all activated quorum disks. If all of the MDisks in the list were to become inaccessible, the system would be unable to backup important data. Operating the system without any online quorum disks is not recommended.

User response

Move one or more quorum disks to MDisks that will remain online.

CMMVC6617E **All available quorum disks are dependent on the drives that you have specified.**

Explanation

The list of drives that you have specified contains all activated quorum disks. If all of the drives in the list were to become inaccessible, the system would be unable to backup important data. Operating the system without any online quorum disks is not recommended.

User response

Move one or more quorum disks to drives that will remain online.

CMMVC6618E **All available quorum disks are dependent on the enclosure that you have specified.**

Explanation

Before removing the enclosure that you have specified, the system must be configured so at least one of the drives that are allocated to hold quorum will remain online when the enclosure goes offline.

User response

Assign one or more drives in the control enclosure as a quorum drive. After you have configured the quorum drives, test for dependencies.

CMMVC6619E **All available quorum disks are dependent on the canister that you have specified.**

Explanation

Before removing the canister that you have specified, the system must be configured so at least one of the drives that are allocated to hold quorum will remain online when the canister goes offline.

User response

Assign one or more of the drives in the control enclosure as a quorum drive. After you have configured the quorum drives, test for dependencies.

CMMVC6620E **The command cannot be initiated because the drives that you have specified are in different I/O groups.**

Explanation

All of the specified drives that comprise the array must be in the same I/O group.

User response

Specify one or more drives in the same I/O group, and resubmit the command.

CMMVC6621E **The command cannot be initiated because the array member that you have specified already exists.**

Explanation

A drive has already been configured for the specified array member. You can use the `lsarraymember` command to display the available members of an array.

User response

Specify an array member without a corresponding drive, and resubmit the command.

CMMVC6622E	The command cannot be initiated because the drive has failed validation tests.
-------------------	---

Explanation

When a drive is made a candidate, the new drive is validated to ensure that adding it to the configuration will not adversely affect the existing or future array status. Either the current status of the drive has not allowed the validation to be performed, or the validation has failed.

User response

Fix any errors associated with the specified drive, or specify a different drive, and resubmit the command.

CMMVC6623E	The command cannot be initiated because the drive validation test has timed out.
-------------------	---

Explanation

When a drive is made a candidate, the new drive is validated to ensure that adding it to the configuration will not adversely affect the existing or future array status. The test timed out, which caused the validation to fail.

User response

Fix any errors that are associated with the specified drive, or specify a different drive, and resubmit the command.

CMMVC6624E	The command cannot be initiated because the drive is not in an appropriate state to perform the task.
-------------------	--

Explanation

The drive that you have specified is offline. A format task is permitted to an offline drive only if the drive has indicated that a format is required and connectivity to the drive is available.

User response

Fix any errors that are associated with the specified drive, or specify a different drive, and resubmit the command.

CMMVC6625E	The command cannot be initiated because a task is in progress on the drive.
-------------------	--

Explanation

A drive can complete only one task at a time. A previous task remains uncompleted. You can monitor the progress of the task using the `lsdriveprogress` command.

User response

Wait for the previous task to complete, and resubmit the command.

CMMVC6626E	The task was not initiated because a command was rejected by the drive that you have specified.
-------------------	--

Explanation

When attempting to initiate a task, a sequence of commands is sent to the drive. One or more of these commands was rejected by the drive that you have specified.

User response

Fix any errors that are associated with the enclosure and cabling, and resubmit the command.

CMMVC6627E	The enclosure that you have specified cannot be changed to managed mode because of a SAS configuration problem that is described in the event log.
-------------------	---

Explanation

The status of the enclosure that you have specified will not allow the enclosure to be managed by the cluster.

User response

Ensure that the enclosure is online and cabled correctly, and resubmit the command.

CMMVC6628E	The enclosure that you have specified cannot be changed to unmanaged mode because one or more drives are in use.
-------------------	---

Explanation

The status of the enclosure that you have specified will not allow the enclosure to be unmanaged by the cluster.

User response

Stop using the drives, and resubmit the command.

CMMVC6630E	A drive dump was not created because a command was rejected by the drive that you have specified.
-------------------	--

Explanation

When initiating a drive dump, a sequence of commands is sent to the drive. One or more of these commands was rejected by the drive that you have specified.

User response

Fix any errors associated with the drive, enclosure, and cabling, or specify a different drive, and resubmit the command.

CMMVC6631E	The task was not completed because the drive that you have specified was unavailable.
-------------------	--

Explanation

The drive that you have specified did not have the required connectivity to complete the task.

User response

Fix any errors associated with the drive, or specify a different drive, and resubmit the command.

CMMVC6953E	The action cannot be completed because volumes are dependent on the specified mdisk. Force is required.
-------------------	--

Explanation

A volume depends on a drive that was specified on the **applydrivesoftware** command.

User response

For systems that support RAID0 arrays, if the drive is a member of a RAID0 array consider whether to introduce more redundancy to protect the data on that drive. If the drive is not a member of a RAID0 array, fix any errors in the event log that relate to the array. When the drive is a member of an array with sufficient redundancy, repeat the command. Alternatively,

consider running the command and specifying the **-force** option.

Warning: With any drive software update, there is a risk that the drive might become unusable. Use the **-force** option only if you accept this risk.

CMMVC6972E	The command cannot be initiated because the maximum number of extents for an MDisk would be exceeded.
-------------------	--

Explanation:

Each MDisk has a limited number of extents, which varies according to the extent size set by the **mdiskgrp**, this limit would be exceeded by this command.

User response

Create a different pool with a larger extent size by using **mkmdiskgrp**. Then, retry the command by using **mdiskgrp**.

Ensure that you are familiar with the maximum configurations of the system. Search for the term "configuration limits and restrictions" in the Search support and downloads search box at the <http://www.ibm.com/support> website. The relationship between extent size and the maximum MDisk capacity is shown in the Extents table.

CMMVC6974E	The command cannot be initiated because there are too many bad blocks on the MDisk.
-------------------	--

Explanation

This error can occur when a managed disk has close to the maximum number of bad blocks, and might reach the maximum number of bad blocks during an expansion process. If the maximum number of bad blocks is reached, the expansion is suspended.

User response

Use the **dumpmdiskbadblocks** and the **lsvdisklba** commands to find bad blocks and rewrite the areas where bad blocks are found. Then, retry the command.

CMMVC6976E	The command cannot be initiated because the MDisk has an array parity rebuild ongoing.
-------------------	---

Explanation

This error can occur when an attempt is made to run a command while an array is not synchronized because data is being rebuilt during a copyback process.

User response

Wait until the data is rebuilt, and then retry the command. You can use the **lsarraysyncprogress** command to view the progress of the synchronization.

CMMVC6977E	The command cannot be initiated because the MDisk has an array initialization ongoing.
-------------------	---

Explanation

This error can occur when an attempt is made to run a command while an array is initializing.

User response

Wait until the array is initialized, and then retry the command. You can use the **lsarrayinitprogress** command to view the progress of the initialization.

CMMVC6978E	The command cannot be initiated because the MDisk has an array member rebuild ongoing.
-------------------	---

Explanation

This error can occur when an attempt is made to run a command while an array member is being rebuilt.

User response

Wait until the array member is rebuilt, and then retry the command. You can use the **lsarraymemberprogress** command to view the progress of the recovery process.

CMMVC6979E	The command cannot be initiated because the MDisk has an array member exchange ongoing.
-------------------	--

Explanation

This error can occur when an attempt is made to run a command while an array member is being exchanged (swapped).

User response

Wait until the array member is exchanged, and then retry the command.

CMMVC6988E	The command cannot be initiated because the maximum number of iSCSI qualified names (IQNs) for the cluster has been reached.
-------------------	---

Explanation

The specified cluster is already configured with the maximum number of IQNs.

User response

None.

CMMVC6998E	The maximum number of iSCSI qualified names (IQNs) plus WWPNs for the cluster is already configured.
-------------------	---

Explanation

The command cannot be initiated because the maximum number of iSCSI qualified names (IQNs) plus WWPNs for the cluster has been reached.

User response

Determine whether the action is required.

If the action is required, review the current configuration to determine whether any current iSCSI qualified name or WWPN definitions are not required. Remove at least one iSCSI qualified name or WWPN that is not required, and resubmit the command.

CMMVC6999E	The command cannot be initiated because the maximum number of iSCSI qualified names (IQNs) for the host has been reached.
-------------------	--

Explanation

The specified host is already configured with the maximum number of IQNs.

User response

None.

CMMVC7003E	The command cannot be initiated because the power supply unit (PSU) that you have specified is offline.
-------------------	--

Explanation

The power supply unit (PSU) that you specify must be online when you submit the command.

User response

Fix any errors associated with the specified PSU. Ensure that the PSU is online, and resubmit the command.

CMMVC7004E	The command cannot be initiated because the node canister port that you have specified does not exist.
-------------------	---

Explanation

You have submitted a command and specified a node canister port that does not exist. You can submit the `lssasfabric` command to show all of the available node canister ports for the associated I/O group.

User response

Specify a node canister port that exists when you submit the command.

CMMVC7005E	The command cannot be initiated because enclosures do not exist for the I/O group that you have specified.
-------------------	---

Explanation

You have submitted a command and specified an I/O group that is not associated with an enclosure. You can submit the `lsencllosure` command to show all of the existing enclosures and their associated I/O groups.

User response

Specify an I/O group that is associated with an enclosure when you submit the command.

CMMVC7006E	The command failed because no enclosures are viewable through the specified canister port.
-------------------	---

Explanation

There are no enclosures on which the command can be run using the parameters that you have specified.

User response

Use the `lssasfabric` command to check whether you have specified the correct node canister port ID and I/O group ID for the enclosures. If none of the enclosures on which you intend to run the command appear in this view, ensure that the enclosures are physically attached, not offline, and that the port that you have specified is not excluded on the node canister or the expansion canister for that enclosure.

CMMVC7007E	The task cannot be initiated because the enclosure that contains the specified drive is not supported.
-------------------	---

Explanation

The `chdrive -use` command specifies a drive for use within a system. However, the enclosure of the specified drive is not a hardware type that is supported for use with the product that you are using.

User response

Ensure that your enclosure is a product supported hardware type.

CMMVC7008E	The task cannot be initiated because the enclosure containing the specified drive is unmanaged and cannot be managed because of an enclosure cabling problem.
-------------------	--

Explanation

The `chdrive -use` specifies a drive for use within a system. However, the enclosure of the specified drive is not managed and is either cabled incorrectly or has incurred a hardware problem on the SAS network. More drives and enclosures cannot be added to the enclosure of the specified drive until the network problem is resolved.

User response

Check the event log, resolve all unfixed errors, and resubmit the command.

CMMVC7009E	The task cannot be initiated because the maximum number of managed enclosures has been reached.
-------------------	--

Explanation

The number of the managed enclosures that can be attached to the system is limited. This limit has been reached.

User response:

None.

CMMVC7010E	The command cannot be initiated because the MDisk mode is set to Array.
-------------------	--

Explanation

This command requires the selected MDisk to be a SAN MDisk (an MDisk that is not an array made from local drives). The selected MDisk has its mode set to Array.

User response

Use `lsmdisk` to list the MDisk, and resubmit the command against an MDisk with a mode other than Array.

CMMVC7011E	The array cannot be created because no quorum disks are currently configured.
-------------------	--

Explanation

When creating an array, quorum disks are required to back up metadata for the array. Creating an array while no quorum disks are configured is not permitted. Quorum disks can be assigned to drives in the control enclosure automatically, or manually by using the **chquorum** command.

User response

Manage the control enclosure, and ensure that all drives within the enclosure are online before resubmitting the command.

CMMVC7012E	The command cannot be initiated because the action will cause the array to go offline.
-------------------	---

Explanation

The array member drives are offline, which can result in an MDisk going offline. An offline MDisk can cause other MDisks in a storage pool to go offline.

User response

Ensure that the drives are online, and resubmit the command.

CMMVC7013E	The command cannot be initiated because a drive within the enclosure that you have specified is configured as a spare or array member.
-------------------	---

Explanation

Each drive within the enclosure that you have specified must not be configured as a spare or array member. One or more of the drives within the specified enclosure do not meet this requirement. Use the **lsdrive** command to see which drives within the enclosure have a drive use of spare or member.

User response

Ensure that no drives within the enclosure are configured as spares or array members, and resubmit the command.

CMMVC7014E	The command cannot be initiated because one or more of the drives are not supported for this RAID level.
-------------------	---

Explanation

Only certain RAID levels are supported in some configurations.

User response

Consult the configuration guide to determine supported RAID levels.

CMMVC7015E	The command cannot be initiated because one or more of the drives are located in the wrong node.
-------------------	---

Explanation

For RAID 0, all of the members must be located in the same node. For RAID 1 or RAID 10, mirrored pairs must be located in different nodes.

User response

Consult the configuration guide to determine which drives to use for the selected RAID level.

CMMVC7016E	Authorization has failed because the private key is not valid for the user name that you have specified.
-------------------	---

Explanation

The private key and user name that you have provided do not match what has been defined on the cluster.

User response

Ensure that the private key is valid for the specified user name, and log in again.

CMMVC7017E	Login has failed because the maximum number of concurrent CLI sessions has been reached.
-------------------	---

Explanation

The cluster supports up to 10 concurrent CLI sessions. The login attempt would have exceeded the supported limit.

User response

Reduce the number of open CLI sessions, and log in again.

CMMVC7018E	The command failed because the requested VDisk size is too large.
-------------------	--

Explanation

The system has a maximum size for virtual disks (VDisks) that is currently 256 TB. While creating a new VDisk or resizing an existing VDisk, you requested a VDisk size that exceeds the maximum.

User response

Resubmit the command with a smaller VDisk size.

CMMVC7019E **The command failed because the VDisk size is not a multiple of 512 bytes.**

Explanation

VDisk capacity must be a complete number of blocks, where one block is 512 bytes. While creating a new VDisk or resizing an existing VDisk, you requested a VDisk size that is an incomplete number of blocks.

User response

Resubmit the command with a valid VDisk size.

CMMVC7020E **The command failed because the maximum number of VDIsks for this I/O group already exist.**

Explanation

The system has a limit of VDIsks per I/O group. A new VDisk cannot be created in an I/O group that has already reached the limit of VDIsks.

User response

Choose another I/O group or delete some VDIsks in this I/O group.

CMMVC7021E **The command failed because the maximum number of VDisk copies already exist.**

Explanation

The system has a limit on the number of VDisk copies that can be created. An additional VDisk copy cannot be created because the limit has been reached.

User response

Delete some existing VDisk copies and resubmit the command.

CMMVC7022E **The command failed because NTP is active.**

Explanation

You have attempted to manually set the cluster time while the cluster is configured to use NTP (network time protocol) to set its time.

User response

Disable NTP, and resubmit the command. If you are trying to set the time manually because the cluster time is incorrect, check the settings on the NTP server.

CMMVC7023E **The command failed because the requested node name is in use as the failover name of another node.**

Explanation

You have attempted to add a node to a cluster or rename a node that is already in the cluster. The new name that you have requested for the node is not valid because one of the nodes in the cluster has been configured with the requested new name as its failover name.

User response

Either resubmit the command specifying a different node name, or modify the configuration of the node in the cluster to change its matching failover name to a different failover name.

CMMVC7024E **The command failed because the maximum number of file systems already exist.**

Explanation

The maximum number of file systems has been reached. Additional file systems cannot be created.

User response

Remove an unused file system and reissue the command, or extend an existing file system by creating the VDisk there.

CMMVC7025E **The command failed because the VDisk is associated with a file system and cannot be removed under your current user role.**

Explanation

You are attempting to remove a VDisk that is associated with a file system. However, you do not possess the required role for file system actions and VDisk removal.

User response

Resubmit the task using the remove VDisk command.

CMMVC7026E **The command failed because VDIsks exist in the file system.**

Explanation

You are attempting to delete an MDisk group with which VDIsks are associated. The MDisk group cannot be removed while the associated VDIsks remain.

User response

Remove the file system VDisks, and resubmit the command to remove the MDisk group.

CMMVC7027E **The command failed because the requested action is not permitted on a VDisk that is in a file system.**

Explanation

The VDisk that you have specified is associated with a file system, which disallows the requested action.

User response

The command cannot be completed on this VDisk. It will only succeed with a VDisk that is not associated with a file system.

CMMVC7028E **The task cannot be completed because the FlashCopy target VDisk that you have specified is in a Metro Mirror or Global Mirror relationship, and the I/O group of the VDisk is different than that of the proposed FlashCopy mapping.**

Explanation

The FlashCopy map must be in the same I/O group as the target VDisk because the VDisk is a component of a remote copy relationship.

User response

Specify the I/O group of the target VDisk when creating the FlashCopy map.

CMMVC7029E **The task cannot be completed because one or more of the target VDisks of the FlashCopy mappings is the primary of a mirroring Metro Mirror or Global Mirror relationship.**

Explanation

The target VDisk is part of a remote copy relationship that is active.

User response

Either force stop the FlashCopy consistency group or stop any remote copy relationships.

CMMVC7030E **The task cannot be completed because the target VDisk of the FlashCopy mapping is the primary of a mirroring Metro Mirror or Global Mirror relationship.**

Explanation

The target of the FlashCopy map is a component of an active FlashCopy map.

User response

Either force stop the FlashCopy map or stop the remote copy relationship.

CMMVC7031E **The task cannot be completed because the FlashCopy mapping target VDisk is a secondary in a Metro Mirror or Global Mirror relationship, or is the primary in an active relationship.**

Explanation

The target VDisk of the FlashCopy map is part of an active remote copy relationship.

User response

Stop the remote copy relationship.

CMMVC7032E **The task cannot be completed because one or more of the target VDisks of the FlashCopy mappings is either a secondary in a Metro Mirror or Global Mirror relationship or the primary of an active relationship.**

Explanation

A target VDisk of a FlashCopy map in the consistency group is part of an active remote copy relationship.

User response

Stop any remote relationships containing a target VDisk of a map in the consistency group.

CMMVC7033E **The task failed because the current hardware configuration is not valid.**

Explanation

You have issued the "chnodehw" command to enable new hardware that is faulty, unsupported, or incompletely installed.

User response

Follow service procedures as prompted by the management GUI to correct the hardware configuration. Then reissue the command.

CMMVC7036E The action failed because quorum is not permitted on the drive that you have specified.

Explanation

Quorum is only permitted on specific drive types. The drive that you have selected will not support quorum.

User response

Reissue the command specifying a different drive.

CMMVC7037E The action failed because the drive cannot be found.

Explanation

You have specified a drive does not appear to exist.

User response

Reissue the command specifying a different drive.

CMMVC7038E The action failed because the system was unable to initialize the quorum disk.

Explanation

A sequence of SCSI commands must be sent to a quorum disk before it can become available for use. One of these SCSI commands has failed.

User response

Fix any errors associated with the disk, choose a different resource for quorum, and then reissue the command.

CMMVC7039E The action failed because the specified drive is not online.

Explanation

The drive that you have specified is offline possibly as a result of errors.

User response

Fix any errors associated with the drive, or choose a different resource for quorum, then reissue the command.

CMMVC7040E The action failed because the specified MDisk is not online.

Explanation

The MDisk that you have specified is offline possibly as a result of errors.

User response

Fix any errors associated with the MDisk, or choose a different resource for quorum, then reissue the command.

CMMVC7041E The action failed because a better quorum candidate is available for use as quorum and override has not been enabled.

Explanation

Quorum disks are selected automatically based on a set of selection criteria. The resource that was selected is inferior to an alternative resource.

User response

Choose a different resource for quorum, or refer to the quorum documentation before using the -override parameter.

CMMVC7042E The action failed because the -override yes parameter was used without a specified drive or MDisk.

Explanation

The -override yes parameter must specify a drive or MDisk.

User response

Reissue the command with the correct syntax.

CMMVC7043E The action failed because the required extents could not be allocated.

Explanation

When an MDisk is specified for quorum, some extents must be allocated for use by the quorum disk. Sufficient extents were not available.

User response

Reissue the command using a different MDisk or migrate data from the MDisk to free up sufficient extents.

CMMVC7044E The action failed because the specified drive is either degraded or excluded.

Explanation

The drive that you have specified either contains errors or is in the Excluded state.

User response

Fix any errors associated with the drive, or choose a different resource for quorum, then reissue the command.

CMMVC7045E The action failed because the specified MDisk is either degraded or excluded.

Explanation

The MDisk that you have specified either contains errors or is in the Excluded state.

User response

Fix any errors associated with the MDisk, or choose a different resource for quorum, then reissue the command.

CMMVC7046E The action failed because the -rsize option must be set to auto.

Explanation

You have run the **mkvdisk** or **addvdiskcopy** command to import a compressed VDisk (using -compressed and -import). The **-rsize** option must be set with a value of **auto**.

User response

Resubmit the command with **-rsize auto**.

CMMVC7047E The action failed because the validate parameter is not supported for compressed VDisks.

Explanation

The command **repairsevdiskcopy -validate** was issued against a compressed VDisk. Unlike thin-provisioned VDisks, compressed VDisks do not support a validation function.

User response

None.

CMMVC7048E The action failed because the compressed VDisk copies are not all corrupted.

Explanation

You have issued the **repairsevdiskcopy** or **recovervdisk -copy** command against a compressed VDisk copy that is not marked as corrupt. Unlike thin-provisioned VDisk copies, the repair process for compressed VDisk

copies can only be run if the system detects that they are corrupted.

User response

The issued command is not required. If the VDisk is offline, consult the *Troubleshooting Guide* to resolve the problem.

CMMVC7049E The command failed because VDisks are obstructing resources required by the compression function.

Explanation

Compression could not be enabled because a VDisk prevented internal resources from being reassigned from cache. A VDisk is offline or data could not be flushed from the cache quickly enough.

User response

If any VDisks are offline, follow service procedures to bring them online before resubmitting the command.

CMMVC7050E The command failed because at least one node in the I/O group does not support compressed VDisks.

Explanation

An attempt was made to create a compressed VDisk in an I/O group that contains at least one node that does not meet these requirements.

User response

Resubmit the command with a different I/O group.

CMMVC7051E The command failed because the I/O group contains compressed volumes. The node being added does not support compressed volumes.

Explanation

An attempt was made to add a node that does not support compression to an I/O group that already contains at least one compressed VDisk.

User response

Add the node to a different I/O group or add a different node to the specified I/O group.

CMMVC7052E The nested group search parameter is not valid for the target LDAP server type.

Explanation

The LDAP server type that you have specified is predefined to perform nested group search.

User response

Check your command to ensure that you have specified the correct type. Remember that the following rules apply to type and -nestedgroupsearch:

- If the type is **itds**, -nestedgroupsearch cannot be processed
- If the type is **ad**, -nestedgroupsearch can only be set to **client** or **off** because there is no server support.
- If the type is **other**, the -nestedgroupsearch parameter is fully configurable

After making your correction, resubmit the command.

CMMVC7053E	The task cannot be initiated because the nested group search value (server) is not valid for the target LDAP server type.
-------------------	--

Explanation

The LDAP server type that you have specified only supports client-side nested group search.

User response

Reissue the task specifying client-side nested group search.

CMMVC7054E	The task cannot be initiated because the user name or password of the LDAP administrator was not specified.
-------------------	--

Explanation

The user name and password of the LDAP administrator are not configured on the cluster as required. Once the credentials are configured, the user name and password can be changed separately.

User response:

Reissue the task specifying both the LDAP administrator user name and password.

CMMVC7055E	The task cannot be initiated because the specified IP address, port, and base distinguished name (DN) are already configured on an LDAP server.
-------------------	--

Explanation

The same IP address, port, and base DN exist on more than one LDAP server.

User response:

Reissue the task specifying an different IP address, port, and base DN.

CMMVC7056E	The task cannot be initiated because the number of LDAP servers has reached the supported maximum.
-------------------	---

Explanation

The cluster limits the number of LDAP servers that can be configured, and the limit has been reached. To remove a configured LDAP server, the `rmldapserver` command can be submitted.

User response:

Remove a configured LDAP server, and resubmit the task.

CMMVC7057E	The task cannot be initiated because the specified LDAP server is the only configured LDAP server.
-------------------	---

Explanation

Removing the specified LDAP server would result in the failure of the remote authentication service.

User response:

Disable the remote authentication service by submitting the `chauthservice` command, and reissue the task.

CMMVC7058E	The task cannot be initiated because no LDAP server is configured.
-------------------	---

Explanation:

The LDAP remote authentication service cannot be used until at least one LDAP server has been configured. To configure LDAP servers, the `mkldapserver` command can be submitted.

User response:

Configure a valid LDAP server, and reissue the task.

CMMVC7059E	The task cannot be initiated because some remote users are not configured with an SSH key and password for the specified remote authentication service.
-------------------	--

Explanation:

An SSH key and password are required for all users of the remote authentication service. To identify remote users without an SSH key and password, the `lsuser` command can be submitted. To configure the user's authentication settings, you can use the `chuser` command.

User response:

Configure the remote users with an SSH key and password or configure the users as local.

CMMVC7060E The task cannot be initiated because the parameters that you have specified are not valid for the LDAP authentication service.

Explanation:

The authentication service URL, user name, password, and SSL certificate are not configurable for the LDAP authentication service.

User response:

Reissue the task specifying valid parameters.

CMMVC7061E The task cannot be initiated because the LDAP administrator user name that you have specified is not valid.

Explanation

LDAP administrator user names must be a valid Distinguished Name, NT login, or User Principal Name.

- Distinguished Names must be a sequence of attribute=value pairs separated by a comma (,), semicolon (;), or plus sign (+), and include special characters and UTF-8 characters that are appropriately escaped with a backslash (\).
- NT logins are valid for Active Directory only and should be in the format DOMAIN\user. They must not start or end with a period (.) and both DOMAIN and user must exclude characters in the set: \ / : ? " < > |
- UPN logins are valid for Active Directory only and must be in the format user@suffix. Both user and suffix must exclude spaces and the following characters: () < > , ; : \ " [] @

User response:

Reissue the task specifying a valid Distinguished Name, NT login, or User Principal Name.

CMMVC7062E The task cannot be initiated because you have specified an LDAP attribute that is not valid.

Explanation:

An LDAP attribute name can contain only alphanumeric characters and hyphens, and the name must begin with a letter.

User response:

Reissue the task specifying a valid LDAP attribute name.

CMMVC7063E The task cannot be initiated because the Distinguished Name that you have specified is not valid.

Explanation:

A Distinguished Name must be a sequence of attribute=value pairs separated by a comma (,), semicolon (;), or plus sign (+) that includes special characters and UTF-8 characters escaped with a backslash (\).

User response:

Reissue the task specifying a valid Distinguished Name.

CMMVC7064E User authentication failed because one or more LDAP servers could not be contacted.

Explanation:

The LDAP server is not operating correctly or an incorrect IP address and port are defined for the LDAP authentication service. The event log has been logged and the corresponding service procedure can be used to resolve this issue. To change the IP address and port of an LDAP server, a security administrator role can submit the chldapserver command.

User response:

Ensure that the LDAP servers are operating correctly. Ensure that the IP address and port defined for each LDAP server is correct, and reissue the task.

CMMVC7065E User authentication failed because a timeout occurred while communicating with one or more LDAP servers.

Explanation:

A timeout occurred while the cluster was attempting to contact the LDAP servers. This timeout might be caused by a TCP/IP network problem, the LDAP servers not operating correctly, or by an incorrect IP address and port being defined for the LDAP servers. The event has been logged and the corresponding service procedure can be used to resolve this issue. To change the IP address and port of an LDAP server, a security administrator can use the chldapserver command.

User response:

Ensure that LDAP servers and the TCP/IP network between them and the cluster are functional. Ensure that the IP address and port defined for each LDAP server is correct, and reissue the task.

CMMVC7066E User authentication failed because an SSL connection could not be established with one or more LDAP servers.

Explanation:

An incorrect LDAP security configuration exists on the cluster or an SSL certificate on the cluster is not valid. The event was logged and the corresponding service procedure is available to resolve this issue. To turn off

transport layer security, a security administrator can submit the `chldap` command or submit the `chldapserver` command to set the SSL certificate for an LDAP server.

User response:

Ensure that the SSL configuration on each LDAP server is correct and that the SSL certificate defined in the cluster for each LDAP server is correct, or ensure that Transport Layer Security is disabled. Then reissue the task.

CMMVC7067E	User authentication failed because one or more LDAP servers rejected an anonymous bind attempt.
-------------------	--

Explanation:

A user name and password were not specified on the cluster for LDAP authentication and the LDAP server has refused an attempt to bind anonymously. The event has been logged and the corresponding service procedure can be used to resolve this issue. To configure a user name and the password for LDAP authentication, a security administrator can submit the `chldap` command.

User response:

Ensure that all LDAP servers are configured to allow anonymous bind, or configure a user name and password for LDAP authentication. Then reissue the task.

CMMVC7068E	User authentication failed because one or more LDAP servers rejected an attempt to bind with the LDAP administrator credentials configured on the cluster.
-------------------	---

Explanation:

A user name and password were configured on the cluster for LDAP authentication and an LDAP server has refused an attempt to bind with these credentials. The event has been logged and the corresponding service procedure can be used to resolve this issue. To change the user name and password defined on the cluster, a security administrator can submit the `chldap` command.

User response:

Ensure that the LDAP credentials configured on the cluster match the credentials that are configured on all LDAP servers, and reissue the task.

CMMVC7069E	User authentication failed because one or more LDAP servers report an incorrect user name or password.
-------------------	---

Explanation:

The user name and password that you have provided do not match any user name and password on the configured LDAP servers. If the password for the user

name has recently changed on the configured LDAP servers, it may be necessary to force the cluster to refresh its authentication cache. To force a refresh, a security administrator can submit the `chauthservice -refresh` command.

User response:

Ensure that the user name and password are correct. Ensure that any recently changed passwords are flushed from the cache of the cluster, and reissue the task.

CMMVC7070E	User authentication failed because the LDAP user attribute is incorrectly configured on one or more LDAP servers.
-------------------	--

Explanation:

The LDAP configuration on the cluster specifies an LDAP user attribute that does not exist on the LDAP server. Users cannot be identified by user name because the attribute is incorrectly configured. The event has been logged and the corresponding service procedure is available to resolve this issue. To specify a different user attribute, a security administrator can submit the `chldap` command.

User response:

Ensure that the LDAP user attribute specified on the cluster is correct. Ensure that the schema on the configured LDAP servers includes the specified attribute, and reissue the task.

CMMVC7071E	User authentication failed because the LDAP group attribute is incorrectly configured on one or more LDAP servers.
-------------------	---

Explanation:

The LDAP configuration on the cluster specifies an LDAP group attribute that does not exist on the LDAP server. The groups to which a user belongs cannot be identified because the attribute is incorrectly configured. The event has been logged and the corresponding service procedure can be used to resolve this issue. To specify a different group attribute, a security administrator can submit the `chldap` command.

User response:

Ensure that the LDAP group attribute specified on the cluster is correct. Ensure that the schema on the configured LDAP servers includes the specified attribute, and reissue the task.

CMMVC7072E	User authentication failed because the LDAP group attribute is not in a valid format on one or more LDAP servers.
-------------------	--

Explanation:

The LDAP group attribute in the user entry on the configured LDAP servers is in an invalid format. The event has been logged and the corresponding service procedure can be used to resolve this issue. The attribute must be a multivalued attribute containing the distinguished names of groups, or a colon-separated list of up to eight user group names.

User response:

Ensure that the LDAP group attribute is correctly formatted on the LDAP servers, and reissue the task.

CMMVC7073E User authentication failed because the LDAP audit log attribute is not configured correctly on one or more LDAP servers.

Explanation:

The LDAP configuration on the cluster specifies an LDAP audit log attribute that does not exist on the LDAP server. The string to use in the audit log cannot be identified because this attribute is incorrectly configured. The event has been logged and the corresponding service procedure can be used to resolve this issue. To specify a different audit log attribute, a security administrator can issue the chldap command.

User response:

Ensure that the LDAP audit log attribute is correctly specified on the cluster. Ensure that the schema on the LDAP servers includes the specified attribute, and reissue the task.

CMMVC7074E The task cannot be initiated because the user could not be found on any of the configured LDAP servers.

Explanation:

The remote user is configured but either no entry for the user exists on the configured LDAP servers, or more than one entry was found. The event has been logged and the corresponding service procedure can be used to resolve this issue.

User response:

Ensure that the user name is unique on the LDAP servers. Ensure that the LDAP bind credentials allow the LDAP server to be searched, and reissue the task.

CMMVC7075I The LDAP task completed successfully.

Explanation

The LDAP task completed successfully.

User response

None.

CMMVC7076E VOLUME cannot be created with VALUE without VALUE.

Explanation:

You are attempting to create a thin provisioned file system volume without compression. Thin provisioned file system volumes must include compression.

User response

Create a thin provisioned file system volume with compression or create a file system volume without thin provisioning.

CMMVC7077E The command failed because adding a thin provisioned copy to a file system volume is not allowed.

Explanation:

You are attempting to add a volume copy to a file system volume that is not compressed but is thin provisioned. Only copies with compression or without thin provisioning can be added to file system volumes.

User response

Add a copy either with compression or without thin provisioning to the file system volume.

CMMVC7078E The command cannot be initiated because adding a copy to the storage pool of file system VDisks is not allowed.

Explanation:

You are attempting to add a volume copy to a file system volume from a different storage pool. Only copies from the same storage pool can be added to file system volumes.

User response

Add a volume copy to a storage pool within the same file system volume, only.

CMMVC7079E The command failed because a volume copy must be different when added to a file system volume.

Explanation:

You are only allowed to add a different volume copy to perform conversions between uncompressed and compressed.

User response

Add a compressed copy to a file system volume with an uncompressed copy or an uncompressed copy to a file system volume with a compressed copy.

CMMVC7080W **The compressed storage used by the cluster is approaching the capacity that is licensed.**

Explanation:

You are being informed that compressed storage in use by the cluster has nearly reached the total licensed capacity.

User response

Compare your actual and planned usage of compression.

CMMVC7081W **The compressed storage used by the cluster has exceeded the capacity that is licensed.**

Explanation:

You are being informed that compressed storage in use by the clustered system exceeds the total licensed capacity.

User response

Reduce the use of compressed storage or purchase additional licensing.

CMMVC7082W **The number of control enclosures with compressed VDisks exceeds the number that are licensed.**

Explanation:

You are being informed that the licensed number of control enclosures that can contain compressed VDisks has been exceeded.

User response

Reduce or consolidate compressed VDisks or purchase additional licensing.

CMMVC7083E **The specified number of control enclosures is not valid.**

Explanation:

The valid range of values for licensed control enclosures is 0–4. The value that you specify must be within this range.

User response

Specify a value between 0 and 4.

CMMVC7084E **The action failed because the command is not permitted for compressed VDisks.**

Explanation:

The command that you have submitted is not valid on compressed volumes.

User response

Do not submit this command for a compressed volume.

CMMVC7102E **The action could not be performed because one or more of the requested secondary VDisk is the target of an active FlashCopy mapping.**

Explanation:

An auxiliary volume cannot be selected as a change volume of a Remote Copy relationship while currently defined for a different relationship.

User response

Choose a different auxiliary volume.

CMMVC7143E **The command cannot be initiated because nodes from another cluster are visible.**

Explanation:

The system layer can be changed only when no other systems are visible on the fabric.

User response

Change the Fibre Channel SAN zoning to remove connectivity between the nodes in the local system and nodes in remote systems, issue 'svctask detectmdisk', then retry the command.

CMMVC7144E **The command cannot be initiated because it is not supported by this hardware type.**

Explanation:

The system layer can only be changed on Storwize family systems.

User response

None.

CMMVC7145E **The command cannot be initiated because one or more partnerships are defined.**

Explanation:

The system layer can only be changed when there are no partnerships defined with remote systems.

User response

Remove all partnerships to remote systems, first removing any associated remote copy relationships and consistency groups using those partnerships, then retry the command.

CMMVC7146E The command cannot be initiated because a host object is associated with SAN Volume Controller ports.

Explanation:

The system layer cannot be changed when there are host objects that contain Fibre Channel ports from SAN Volume Controller nodes or Storwize family systems.

User response

Remove all host objects that contain node ports, then retry the command.

CMMVC7147E The command cannot be initiated because one or more MDisks are provided by a storage system that does not support the system layer changing.

Explanation:

The system layer cannot be changed if MDisks are currently being provided by a Storwize system.

User response

For each MDisk provided by a Storwize system, remove that MDisk from its storage pool. Once all such MDisks have been removed, change the Fibre Channel SAN zoning to remove connectivity between the nodes in the local system, and the nodes in the remote Storwize system. Finally, execute the **detectmdisk** command, and then change the system layer.

CMMVC7154E The task cannot be completed because the specified FlashCopy mapping is controlled by a Metro Mirror or Global Mirror relationship.

Explanation:

The Metro Mirror or Global Mirror relationship under which the specified FlashCopy mapping is controlled prevents completion of the task.

User response

Check whether the specified task is permitted under the configuration of the Metro Mirror or Global Mirror relationship.

CMMVC7155E The Create FlashCopy mapping task cannot be initiated because the source or target VDisk is being used as a change VDisk for a Metro Mirror or Global Mirror relationship.

Explanation:

A volume cannot become the source or target of a FlashCopy mapping while in use as a change volume in a Metro Mirror or Global Mirror relationship.

User response

Specify a volume other than the source or target that is currently in use.

CMMVC7156E The change VDisk could not be associated because it is already a source or target volume in an existing FlashCopy mapping.

Explanation:

A change volume cannot be associated if the same volume is the source or target of a FlashCopy mapping.

User response

Specify a volume other than the source or target that is currently in use.

CMMVC7157E The change VDisk could not be associated because the Metro Mirror or Global Mirror relationship has a volume on this cluster that is the target of a FlashCopy mapping in a different I/O group.

Explanation:

The I/O group of the change volume conflicts with an I/O group in the relationship with which an association was attempted.

User response

Ensure that no conflicting I/O groups exist.

CMMVC7158E The change VDisk could not be associated because the Metro Mirror or Global Mirror relationship has a volume on this cluster that is already involved in the maximum number of FlashCopy mappings.

Explanation:

The change volume cannot cause another volume to exceed the number of FlashCopy mappings allowed.

User response

Reduce the number of FlashCopy mappings in the volume that has reached its maximum.

CMMVC7159E The change volume could not be associated because the relationship has a volume on this cluster that is in an I/O group with no online nodes or because there

are unrecovered FlashCopy mappings in the I/O group.

Explanation:

FlashCopy metadata was lost and cannot be recovered.

User response

The nodes of the I/O group must be brought online before the change volume can be associated. If the nodes of the I/O group were removed, then delete any FlashCopy mappings that existed prior to removing the nodes. .

CMMVC7160E The change VDisk could not be associated because the I/O group has insufficient free bitmap space.

Explanation:

The I/O group must have additional bitmap space to allow the change volume to be associated.

User response

Increase the total bitmap space of the I/O group.

CMMVC7161E The change VDisk could not be associated because the master change volume can only be configured from the master cluster, and the auxiliary change volume from the auxiliary cluster. The change volume must be configured from the remote cluster.

Explanation:

A change volume must be associated from a cluster of the same type (master or auxiliary).

User response

Configure the change volume from the remote cluster.

CMMVC7162E The change VDisk could not be associated because one is already configured for the specified Metro Mirror or Global Mirror relationship.

Explanation:

A change volume has been previously configured for the specified Metro Mirror or Global Mirror relationship.

User response

Ensure that the change volume is associated where a change volume has not been configured.

CMMVC7163E The change VDisk could not be associated because it is already involved in a Metro Mirror or Global Mirror relationship.

Explanation:

The change volume is currently associated with a Metro Mirror or Global Mirror relationship.

User response

Choose an unassociated change volume for the specified Metro Mirror or Global Mirror relationship.

CMMVC7164E The change VDisk could not be associated because its size is different from those in the Metro Mirror or Global Mirror relationship.

Explanation:

A change volume cannot be associated with volumes of a different size.

User response

Choose a change volume with a size that matches those with which it is being associated.

CMMVC7165E The change VDisk could not be disassociated because the Metro Mirror or Global Mirror relationship does not have one configured.

Explanation:

An attempt was made to disassociate a change volume where one does not currently exist.

User response

Verify whether the intended change volume was specified.

CMMVC7166E The change VDisk could not be disassociated because it is currently in use by the Metro Mirror or Global Mirror relationship.

Explanation:

An attempt was made to disassociate a change volume that is currently in use.

User response

Verify whether the intended change volume was specified.

CMMVC7167E The change VDisk could not be associated because it is mapped to a host.

Explanation:

A change volume cannot be associated if it is mapped to a host.

User response

Unmap the change volume from its host, or choose a different change volume.

CMMVC7168E **The VDisk-to-host mapping was not created because the VDisk is a change VDisk for a Metro Mirror or Global Mirror relationship.**

Explanation:

A volume cannot be mapped to a host if it is associated as a change volume.

User response

Choose a different change volume.

CMMVC7169E **The Remote Copy relationship could not be deleted because this would corrupt the secondary VDisk.**

Explanation:

The deletion of the relationship is being prevented as a safeguard against corrupting the secondary. The result can be prevented by allowing resynchronization, or by overriding the safeguard.

User response

Allow the relationship to become synchronized before deleting, or reissue the command with the -force flag to allow corruption of the secondary.

CMMVC7170E **The Remote Copy relationship could not be created because the specified master VDisk is already a change VDisk for a different relationship.**

Explanation:

A master volume cannot be selected as a change volume of a Remote Copy relationship while currently defined for a different relationship.

User response

Choose a different master volume.

CMMVC7171E **The Remote Copy relationship could not be created because the specified auxiliary volume is already a change volume for a different relationship.**

Explanation:

An auxiliary volume cannot be selected as a change volume of a Remote Copy relationship while currently defined for a different relationship.

User response

Choose a different auxiliary volume.

CMMVC7172E **Enabling access to the secondary VDisk of the Remote Copy relationship could not be completed in a reasonable time.**

Explanation:

A timeout occurred before the task could be completed. The relationship is continuing to enable access, and will have a state of idling when access is enabled.

User response

Check the event log for any events to be resolved, and resubmit the task.

CMMVC7173E **Enabling access to the secondary VDisks of the Remote Copy consistency group could not be completed in a reasonable time.**

Explanation:

A timeout occurred before the task could be completed. The consistency group is continuing to enable access, and will have a state of idling when access is enabled.

User response

Check the event log for any problems that need to be resolved, and resubmit the task.

CMMVC7174E **The task cannot be completed because the other cluster is running a software version that is not recent enough.**

Explanation:

The software version of the one of the clusters is not supported.

User response

update the software version of the cluster.

CMMVC7175E **Enabling access to the secondary VDisks of the Remote Copy consistency group could not be completed because the relationships in the group are not mutually consistent.**

Explanation:

The relationships in the consistency group must be mutually consistent before access to the secondary volumes can be enabled.

User response

Ensure that the relationships in the Remote Copy consistency group are mutually consistent.

CMMVC7176E The Remote Copy relationship could not be added to the consistency group because the cycling modes do not match.

Explanation:

The cycling modes of the Remote Copy relationship and the consistency group to which it is being added must match.

User response

Ensure that the cycling modes match.

CMMVC7177E The Remote Copy relationship could not be added to the consistency group because the cycling periods do not match.

Explanation:

The cycling periods of the Remote Copy relationship and the consistency group to which it is being added must match.

User response

Ensure that the cycling periods match.

CMMVC7178E The Remote Copy relationship could not be started in a reasonable time. It is now stopped.

Explanation:

A timeout occurred before the task could be completed.

User response

Check the event log for any problems that need to be resolved, and resubmit the task.

CMMVC7179E The Remote Copy consistency group could not be started in a reasonable time. It is now stopped.

Explanation:

A timeout occurred before the task could be completed.

User response

Check the event log for any problems that need to be resolved, and resubmit the task.

CMMVC7180E The Remote Copy relationship could not be started because no master change VDisk is defined.

Explanation:

A master change volume must be defined for the Remote Copy relationship.

User response

Define a master change volume.

CMMVC7181E The Remote Copy relationship could not be started because no auxiliary change VDisk is defined.

Explanation:

An auxiliary change volume must be defined for the Remote Copy relationship.

User response

Define an auxiliary change volume.

CMMVC7182E The Remote Copy consistency group could not be started because no master change VDisk is defined.

Explanation:

A master change volume must be defined for the Remote Copy consistency group.

User response

Define a master change volume.

CMMVC7183E The Remote Copy consistency group could not be started because no auxiliary change VDisk is defined.

Explanation:

An auxiliary change volume must be defined for the Remote Copy consistency group.

User response

Define an auxiliary change volume.

CMMVC7184E The task cannot be completed as the Remote Copy object is not stopped.

Explanation:

The task cannot be completed as the Remote Copy object is not stopped.

User response

Stop the Remote Copy object.

CMMVC7185E **The change VDisk could not be associated because the Metro Mirror or Global Mirror relationship has a volume on this cluster that is in a different I/O group.**

Explanation:

The I/O group of the change volume conflicts with an I/O group in the relationship with which an association was attempted.

User response

Ensure that no conflicting I/O groups exist.

CMMVC7186E **The Remote Copy relationship was not created because the master VDisk is owned and has restricted use.**

Explanation:

The specified task cannot be performed while the master volume is in a file system or owned.

User response

Choose a different master volume, if the specified volume cannot be removed from the file system.

CMMVC7187E **The Remote Copy relationship was not created because the auxiliary VDisk is owned and has restricted use.**

Explanation:

The specified task cannot be performed while the auxiliary volume is in a file system or owned.

User response

Choose a different auxiliary volume, if the specified volume cannot be removed from the file system.

CMMVC7188E **The command failed because the master virtual disk (VDisk) is in a file system.**

Explanation:

The specified task cannot be performed on a master volume while it is in a file system.

User response

Choose a different master volume, if the specified volume cannot be removed from the file system.

CMMVC7189E **The change VDisk could not be associated because it is in a file system.**

Explanation:

The specified change volume cannot be associated while it is in a file system.

User response

Choose a different change volume, if the specified volume cannot be removed from the file system.

CMMVC7203E **The command failed because the hardware configuration of the local cluster is not compatible with the code of a partnered cluster.**

Explanation:

The hardware configuration of the local cluster is not compatible with the code of a partnered cluster. See the chnodehw explanation for more information.

User response

Make sure the hardware configuration and code level of all the clusters in a partnership are compatible before you create the partnership. Run chnodehw for diagnostic information.

CMMVC7204E **Cannot remove the last I/O group from the volume access set.**

Explanation

A volume must have at least one I/O group in an access set. All of the I/O groups cannot be removed from a volume access set.

User response

Before you run the command again, complete one of the following steps:

- Modify the I/O group list so that the list does not include all of the I/O groups that provide access to the volume.
- Add I/O groups to the access set.

CMMVC7205E **The command failed because it is not supported.**

Explanation:

The command fails because it is not supported by the product.

User response

Review the documentation for the product to select an appropriate command.

CMMVC7206E The command failed because a parameter is not supported.

Explanation:

The user entered a parameter which is not supported by the product they are using.

User response

Review the documentation and select appropriate parameters for the product.

CMMVC7210E The command failed because it would create too many compressed volume copies that are contained within regular pools in the I/O group.

Explanation

The number of compressed copies within regular pools in an I/O group is limited to 200 or 512, depending on the platform type. This limitation does not apply to compressed copies in data reduction pools.

User response

Complete one of the following actions:

- Delete compressed copies from regular pools in the I/O group, then retry the command.
- Retry the command and specify a data reduction pool for the compressed copies.
- Retry the command for a different I/O group.

CMMVC7211E The command failed because it is not supported for image-mode MDisks.

Explanation

This error is returned by the remove mdisk **rmmdisk** command when issued against an MDisk that is backing an image-mode volume on a platform that does not support migration for image-mode volumes.

User response

If the image-mode volume is not required then use **rmvdisk** to delete the volume. This deletes the MDisk as well. If the user wants to migrate the image-mode volume's data to internal storage, do that using Volume Mirroring and then delete the image-mode volume copy.

CMMVC7218E The task cannot be initiated because an invalid license key was specified.

Explanation:

The license key specified has not been recognized as a valid key.

User response

Check for typing errors and try again.

CMMVC7219E The task cannot be initiated because an invalid function id was specified.

Explanation:

The function id specified in the command is invalid. There are a set number of features that can be activated. This message is shown when the user specifies an invalid function id.

User response

Use **lsfeature** to check which function id to specify.

CMMVC7220E The task cannot be initiated because an invalid function license key file path was specified.

Explanation:

The file path specified for the license key file is invalid.

User response

Check for typing errors and try again.

CMMVC7221E The command has failed because the machine signature in the license does not match this machine.

Explanation:

The license key provided is not valid for this storage system.

User response

Use a license key that has been generated using this enclosure's machine signature.

CMMVC7222E The command has failed because the function specified by the license key has not been recognized.

Explanation:

The license key specified is for activating a function that is not supported on this level of firmware.

User response

update the storage system to a firmware level that supports the function and try again.

CMMVC7223E The command has failed because the trial specified has previously been used.

Explanation:

Each function has a trial period that can only be redeemed once. The trial period on this machine has already been used.

User response

Purchase the full license in order to continue using this function.

CMMVC7224E The command has failed because the specified function is currently in use.

Explanation:

A function can only be deactivated if it is no longer in use.

User response

Ensure that the function that you need to deactivate is no longer in use, and try again.

Reduce the number of FlashCopy targets to 64 or fewer before deactivating the function.

CMMVC7226E The command has failed because the license key file specified is not in a supported format

Explanation

The command has failed because the license key file specified is not in a supported format.

User response

Check that the correct file was uploaded and try again.

CMMVC7233W Easy Tier is active without a license for each enclosure.

Explanation:

The system does not have enough licenses for Easy Tier.

User response

The user should correct their Easy Tier license entitlement.

CMMVC7234W FlashCopy is enabled without a license for each enclosure.

Explanation:

The system does not have enough licenses for FlashCopy.

User response

The user should correct their FlashCopy license entitlement.

CMMVC7235W Remote copy is enabled without a license for each enclosure.

Explanation:

The system does not have enough licenses for remote copy.

User response

The user should correct their Remote copy license entitlement.

CMMVC7236W Multiple functions are enabled without a license for each enclosure.

Explanation:

The system does not have enough licenses for multiple functions.

User response

The user should correct their license entitlement.

CMMVC7238E The cycling mode may only be changed for Global Mirror relationships or groups.

Explanation

An attempt was made to change to cycling mode for an active-active relationship. This action is not permitted.

User response

If you must use cycling mode, you must change the relationship to Global Mirror by using the **chrcrelationship** command. This scenario is not common.

CMMVC7239E The node could not be added because the number of configured hosts exceeds the supported limit for the node type being added.

Explanation

One (or more) I/O groups has more hosts configured than is supported by the node hardware type being added.

User response

Either reduce the number of configured hosts or choose a different node hardware type to add.

CMMVC7240E The node could not be added because at least one host has more volumes mapped than is supported for the node type being added.

Explanation

One (or more) hosts has more volumes mapped than is supported by the node hardware type being added.

User response

Either reduce the number of volumes mapped or choose a different node hardware type to add.

CMMVC7241E System code update cannot start because a component firmware update is in progress.

Explanation:

An attempt was made to initiate either a system code update or a firmware update while the system was updating the firmware of various hardware components. This update cannot be completed while a firmware download is in progress, so the request failed.

User response

The firmware download must complete before you can perform another update. Due to the dynamic nature of firmware downloads, you cannot follow the progress of the download. Wait approximately 10 minutes and retry the command. You might need to repeat this step several times. You can use the **svcinfo lsupdate** command to see whether the firmware download completed.

CMMVC7242E No help available for [%1].

Explanation:

There is no help available for this command. [%1] shows the command for which help is not available.

User response

None.

CMMVC7243E The specified port mask cannot be applied because insufficient paths would exist for node communication.

Explanation:

The localfcportmask port mask value that was specified would cause one or more nodes to lose contact with the system.

User response

Check zoning. Fix any port errors in the event log. Use the lsfabric CLI command to ensure that when the correct port mask is specified and applied, all nodes would still have two paths to contact every other node in the system.

CMMVC7248E You must use an 0x parameter for the -drivelba parameter.

Explanation:

The parameter format for the **lsmdisklba** might be in error. See the description of the command to find an acceptable format.

User response:

Try the command again using the parameter format described in the command documentation.

CMMVC7249E The name that you have entered is not valid. The name can contain letters, numbers, spaces, periods, dashes, and underscores. The name must not begin or end with a space. The name must not begin with a period.

Explanation

A period or space cannot be the first character and a space cannot be the last character in the name that you enter. Also, the following characters are not supported anywhere in the name: * : , " ' % #

User response

Ensure that the name you enter does not begin with a period, does not begin or end with a space character, and does not contain any of the unsupported characters listed above, and resubmit the task.

CMMVC7300E The maximum number of volumes already exist.

Explanation:

The maximum number of volumes have been created and one or more must be deleted.

User response

Destroy one or most of the volumes before more can be created.

CMMVC7301E The command failed because the volume would be smaller than the minimum size.

Explanation:

A volume must be 1 MB or greater to be successfully created.

User response

Specify a capacity which is greater than the minimum supported capacity (1MB).

CMMVC7302E The command failed because insufficient extents are available.

Explanation:

Too many volumes have been created. Contact IBM support for assistance.

User response

If possible, delete unused volumes and try again. If the error persists, the extent mapping must be defragmented.

Contact IBM support for assistance.

CMMVC7304E	The command cannot be initiated because a spare is already configured.
-------------------	---

Explanation:

A configured spare already exists.

User response:

Only new drives can be formatted. If a spare already exists, the command cannot be executed.

CMMVC7305E	The command cannot be initiated because the drive fault is unrecoverable.
-------------------	--

Explanation:

A drive fault is preventing further actions.

User response:

Replace the drive.

CMMVC7306E	The command cannot be initiated because no array currently exists.
-------------------	---

Explanation:

No array has been created. No further action is possible.

User response:

Create an array before using this command.

CMMVC7307E	The command cannot be initiated because the battery slot number specified is invalid.
-------------------	--

Explanation:

Batteries occupy slot numbers 1 and 2 only for batteries.

User response:

Select Slot 1 or 2.

CMMVC7308E	The command cannot be initiated because an array already exists.
-------------------	---

Explanation:

An array exists that is prohibiting the desired action.

User response:

Only a single array can be created. Either create new volumes on the same array, or remove all volumes and arrays, then recreate the array.

CMMVC7309E	The command cannot be initiated because the specified raid level is unsupported on this platform.
-------------------	--

Explanation:

This error message is displayed when the RAID level that is specified in a command is not supported by the system.

User response:

Retry the command, specifying a supported RAID level.

CMMVC7310E	The command cannot be initiated because one or more drives is in the failed state.
-------------------	---

Explanation:

One or more drives has failed and is preventing most commands.

User response:

Work through Directed Maintenance Procedures (DMP) associated with failed drives.

CMMVC7311E	The command cannot be initiated because the number of drives is unsupported.
-------------------	---

Explanation

The number of installed drives is incorrect for the array configuration, or the capacity of the drives is not uniform.

- RAID 0 requires at least one drive.
- RAID 5 requires at least three drives.
- All the drives in an array must have the same capacity.

User response:

Remove or insert drives to obtain a supported configuration.

CMMVC7312E	The command could not be initiated because one or more volumes are using the array.
-------------------	--

Explanation:

One or more volumes are already using the array. All volumes must be removed before removing the array.

User response:

Remove all volumes before removing the array.

CMMVC7313E	The specified array does not require recovery as it is not corrupt.
-------------------	--

Explanation:

The specified array is not corrupt and does not require repair.

User response:

This command is only supported for corrupt arrays.

CMMVC7314E	The specified array cannot be recovered due to failed drives.
-------------------	--

Explanation:

One or more drives in an array have failed and this is preventing recovery.

User response:

Put the drives back in if they are missing.

CMMVC7315E The command cannot be initiated because the specified slot does not exist.

Explanation:

The command was attempted on an invalid slot.

User response

Batteries have slots 1 and 2. Enclosures have slots 3-12.

Retry command with a slot that exists.

CMMVC7316E The specified array cannot be recovered due to failed drives.

Explanation:

One or more failed drives are preventing the desired action. Too many errors.

User response:

Change the volume SCSI Drive ID by enabling volume Open Access.

CMMVC7317E The command cannot be initiated because the specified PSU does not exist.

Explanation:

A requested PSU does not exist.

User response:

Select another PSU or install the requested PSU.

CMMVC7318E Open access is not enabled.

Explanation:

Host mappings or logical host already exist.

User response:

Delete host mappings or the logical host.

CMMVC7319E The air filter must be enabled to change the period.

Explanation:

To change the timer for the air filter, the filter must currently be in use.

User response:

Enable the filter timer, then try the command again.

CMMVC7320E Invalid port mask supplied.

Explanation:

An invalid port mask was supplied.

User response:

Review the command parameters and try again with corrected value.

CMMVC7321E Mask cannot be applied because insufficient paths exist for node communication.

Explanation:

An invalid port mask was supplied.

User response:

Review the command parameters and try again with corrected value.

CMMVC7322E Another volume uses this SCSI ID.

Explanation:

The SCSI ID is already in use.

User response:

Use a different SCSI ID or remove the other volume.

CMMVC7323E The command cannot be initiated due to a hardware fault.

Explanation:

A hardware fault has occurred. Follow the Directed Maintenance Procedures (DMP).

User response

An unknown hardware fault exists.

Follow the DMP to resolve the hardware fault.

CMMVC7324E The command cannot be initiated because the drive task is not supported.

Explanation:

The drive does not support the command.

User response:

None.

CMMVC7325E Open Access setting not changed because hosts exist.

Explanation:

You cannot change the state of Open Access when hosts are defined.

User response:

Remove the hosts and try the command again.

CMMVC7326E Cannot create logical host because open access is enabled.

Explanation:

Open Access is preventing the creation of a logical host.

User response:

Disable Open Access if host mapping access is desired

CMMVC7329E The maximum number of Infiniband GIDs for the host is already configured.

Explanation:

The command has failed because the maximum number of Infiniband addresses has been exceeded.

User response:

Remove unused hosts addresses and try again.

CMMVC7330E An invalid Infiniband GID was entered.

Explanation:

The Infiniband address entered is not a valid address.

User response:

Check your input and try again.

CMMVC7331E A supplied Infiniband GID is already assigned to another host.

Explanation:

The Infiniband address configured is already assigned to a configured host.

User response:

Check your input and try again.

CMMVC7332E The array does not exist.

Explanation:

A flash memory array was not found by the Command Console LUN (CCL).

User response:

Call IBM support for instructions to resume your failed upgrade.

CMMVC7334E The array could not be removed because it is initializing.

Explanation:

A Remove Array operation was attempted while a newly created array was initializing.

User response:

Allow the array to complete initialization before attempting to remove it.

CMMVC7335E The encryption state cannot be changed when an array exists.

Explanation

An attempt was made to change the encryption state of the system when an array was present.

User response

Remove the array by using the **rmarray** command, then retry the **chencryption** command.

CMMVC7336E The topology and speed are not compatible with the specified port.

Explanation:

The user has entered a combination of speed and topology which is not compatible.

User response:

Check your input and try again.

CMMVC7337E The command cannot be initiated because the encryption key was not found.

Explanation

The system cannot locate a correct encryption key.

User response

Provide the current master encryption key to the system before you retry the command. If you use USB flash drives to manage the master encryption key of this system, connect one of the USB flash drives containing the current key to each node. If you are using a key server to manage encryption keys of this system, ensure that the system, key servers, and network are configured correctly so that a key server that contains the current master encryption key is online to the system.

CMMVC7338E The command cannot be initiated because the encryption key is not valid.

Explanation

The encryption key that was provided cannot be used.

User response

Provide the current master encryption key to the system before you retry the command. If you use USB flash drives to manage the master encryption key of this system, connect one of the USB flash drives containing the current key to each node. If you are using a key server to manage encryption keys of this system, ensure that the system, key servers, and network are configured correctly so that a key server that contains the current master encryption key is online to the system.

CMMVC7339E The command cannot be initiated because the drive did not unlock.

Explanation

The system was unable to unlock the drive by using the encryption key that was provided.

User response

Provide the current master encryption key to the system before you retry the command. If you use USB flash drives to manage the master encryption key of this system, connect one of the USB flash drives containing the current key to each node. If you are

using a key server to manage encryption keys of this system, ensure that the system, key servers, and network are configured correctly so that a key server that contains the current master encryption key is online to the system.

CMMVC7340E The command cannot be initiated because the array is offline.

Explanation:

Failure to create a volume because the array specified is offline.

User response

Bring the array online.

CMMVC7341E The update cannot be resumed at this time.

Explanation:

The update cannot proceed because of hardware errors.

User response

Contact IBM support.

A service mode update may be necessary.

CMMVC7342E The array is already encrypted.

Explanation:

The array is already encrypted.

User response:

No response required.

CMMVC7343E A software upgrade is in progress and must finish before battery reconditioning can be started.

Explanation:

Battery reconditioning cannot be performed while a software upgrade is in progress.

User response:

Wait until the software upgrade has finished, and then restart battery reconditioning.

CMMVC7344E Battery reconditioning is not currently running.

Explanation:

Battery reconditioning is not running, therefore it cannot be cancelled.

User response:

No response required.

CMMVC7348E One of the batteries is currently reconditioning. Wait until reconditioning finishes.

Explanation:

Battery reconditioning is already running on one of the batteries. Only one battery can be reconditioned at a time.

User response:

Wait until the current battery reconditioning finishes before reconditioning another battery.

CMMVC7349E The other battery in the enclosure is not in a good and charged state.

Explanation:

Both batteries in the enclosure must be in a good and charged state to maintain redundancy during the battery reconditioning process. The selected battery cannot be reconditioned because the other battery in the storage enclosure is not charged, not installed, or it has an unresolved error condition.

User response:

Determine the condition of the other battery in the storage enclosure and take appropriate action. For example, install the battery if it is missing. If the battery has an error condition, check the event log and follow the recommended Directed Maintenance Procedure (DMP).

CMMVC7350E The selected battery cannot be reconditioned.

Explanation:

The selected battery is not in a state in which it can be reconditioned. The battery is either not charged, not installed, or it has an unresolved error condition.

User response:

Determine the condition of the selected battery and take appropriate action. For example, install the battery if it is missing. If the battery has an error condition, check the event log and follow the recommended Directed Maintenance Procedure (DMP).

CMMVC7351E Encryption cannot be disabled while an encrypted array exists.

Explanation:

System encryption cannot be disabled if there is an encrypted array.

User response:

Delete the encrypted array and then disable encryption.

CMMVC7352E The array cannot be encrypted because system encryption is disabled.

Explanation:

The array cannot be encrypted because system encryption is disabled.

User response:

Enable system encryption using the chencryption command and retry.

CMMVC7353E The command cannot be initiated because a rekey operation is in progress.

Explanation:

The command cannot execute because there is a rekey operation in progress.

User response:

Wait for the rekey operation to complete, and then re-enter the command. Use the lsencryption command to verify the status of the rekey operation.

CMMVC7354E Rekey operation failed.

Explanation:

The rekey operation failed, possibly due to hardware errors or a missing USB drive.

User response

Provide the current master encryption key to the system before you retry the command. If you use USB flash drives to manage the master encryption key of this system, connect one of the USB flash drives containing the current key to each node. If you are using a key server to manage encryption keys of this system, ensure that the system, key servers, and network are configured correctly so that a key server that contains the current master encryption key is online to the system.

Examine the event log to check for hardware errors. Contact IBM Support if you are unable to determine the cause.

CMMVC7355E The command cannot be initiated because system encryption is not enabled.

Explanation:

The command entered by the user requires system encryption to be enabled.

User response:

Enable system encryption and then re-enter the command.

CMMVC7356E Unable to validate the key on the current USB drive.

Explanation:

Validation failed. Insert the USB drive that contains the correct key for this system.

User response:

Review the output of the lseventlog and lsencryption commands for additional information, and take appropriate corrective action.

CMMVC7357E The command cannot be initiated because a drive has failed.

Explanation:

The command cannot be initiated because a drive has failed.

User response:

Resolve the problem that caused the drive to fail before retrying the operation. Review the event log for possible causes.

CMMVC7358E Rekey commit not allowed until keys have been copied.

Explanation:

An attempt was made to commit a new key without making sufficient copies of the new key.

User response:

Contact IBM Support.

CMMVC7359E Operation not applicable when encryption is disabled.

Explanation:

Either key validation was attempted while system encryption was disabled, or an attempt was made to change an array from unencrypted to encrypted while system encryption was disabled.

User response:

Enable system encryption and retry the command.

CMMVC7360E The command cannot be executed because the array is not online.

Explanation:

The array has to be online to run recoverarray - validate.

User response:

Use the lsarray command to check the value of the attribute parameter raid_status for the array. The command cannot be run if the array does not exist, or if the raid_status is **offline**, **degraded**, **syncing**, or **initiating**.

CMMVC7361E The command cannot be initiated because another operation is in progress on the array.

Explanation:

Another operation on the array is already in progress.

User response:

Wait until the current operation is completed before running another command.

CMMVC7362I The encryption copy tool should only be used with the assistance of support.

Explanation:

The command should only be run with the assistance of a support representative.

User response

Contact your support representative.

Attention: Do not proceed without the assistance of a support representative.

CMMVC7363E The system is unable to mount/unmount the USB drive.

Explanation:

The command was unable to either mount or dismount the USB drive.

User response

Contact your support representative.

Attention: Do not proceed without the assistance of a support representative.

CMMVC7364E The system is unable to collect the information needed to provide the proper output from the lsencryption command.

Explanation:

The command is unable to collect the output of the lsencryption command.

User response

Contact your support representative.

Attention: Do not proceed without the assistance of a support representative.

CMMVC7365E The system could not complete the key copy operation because it could not read the new key file.

Explanation:

The new key file was not found on the USB drive or the key server.

User response:

Provide the current master encryption key to the system before you retry the command. If you use USB flash drives to manage the master encryption key of this system, connect one of the USB flash drives containing the current key to each node. If you are using a key server to manage encryption keys of this system, ensure that the system, key servers, and network are configured correctly so that a key server that contains the current master encryption key is online to the system. Contact IBM Support if you are unable to resolve the problem.

CMMVC7366E The system could not complete the key copy operation because it could not read the current key file.

Explanation:

The current key file was not found on the USB drive or the key server.

User response:

If a key copy operation is running on a new system for the first time, then no response is necessary. Otherwise, provide the current master encryption key to the system before you retry the command. If you use USB flash drives to manage the master encryption key of this system, connect one of the USB flash drives containing the current key to each node. If you are using a key server to manage encryption keys of this system, ensure that the system, key servers, and network are configured correctly so that a key server that contains the current master encryption key is online to the system. Contact IBM Support if you are unable to resolve the problem.

CMMVC7367E The key file is not valid.

Explanation:

The key file is not valid.

User response

Ensure that the correct USB drive that contains the current master encryption key is inserted. You might need to insert a USB drive that contains a backup copy of the current master encryption key. Contact IBM Support if you are unable to resolve the problem.

If a USB flash drive fails, securely discard it and replace it with a new USB flash drive. Copy the key file from a known good USB flash drive to the new USB flash drive.

CMMVC7368I %1 additional copy has been made.

Explanation:

Copy # %1 of the new key was made.

User response

No response required.

This is an informational message that states how many copies of the new key have been made.

CMMVC7369E No additional key copies were written to the USB drive; all required keys already exist on the drive.

Explanation:

No additional keys were written to the USB drive because both the new and current keys already exist on the drive.

User response:

Insert a new USB drive that does not contain any key files and retry the command, or call IBM Support to continue.

CMMVC7370W Only the new key file has been copied to the USB drive; the current key was already on the drive.

Explanation:

Only the new key file has been written to the USB drive; the current key was already on the drive.

User response:

The USB drive already contains the current key file. If the USB drive was expected to be empty, examine the files on the drive to determine the problem.

CMMVC7371E Only the current key file has been copied to the USB drive; the new key was already on the drive.

Explanation:

Only the current key has been written to the USB drive; the new key was already on the drive. Call IBM Support to continue.

User response:

Call IBM Support to continue. Do not proceed without IBM Support assistance.

CMMVC7372E The current key on the USB drive does not match the key that was previously read.

Explanation:

The current key on the USB drive does not match the key that was previously read.

User response:

Call IBM Support to continue. Do not proceed without IBM Support assistance.

CMMVC7373E The attempted write of the new key to the USB drive has failed.

Explanation:

The attempted write of the new key to the USB drive has failed.

User response:

Ensure that the correct USB drive is inserted. Call IBM Support if unable to resolve the problem.

CMMVC7374E The attempted write of the current key to the USB drive has failed.

Explanation:

The attempted write of the current key to the USB drive failed.

User response:

Ensure that the correct USB drive is inserted. Call Support if unable to resolve the problem.

CMMVC7375E No keys were written to the USB drive. Do not proceed without Support assistance.

Explanation:

No keys were written to the USB drive. Contact your support representative.

User response

Contact your support representative.

Attention: Do not proceed without the assistance of a support representative.

CMMVC7376E The command cannot be run because an encryption key has not been created.

Explanation:

This command requires an encryption key, but the encryption state has not been properly set up.

User response:

Use the encryption enablement procedure to create encryption keys, or contact IBM Support for assistance.

CMMVC7377E The command cannot be executed because the array does not exist.

Explanation:

This command requires an encryption key, but the encryption state has not been properly set up.

User response:

Create an array and then reattempt the command.

CMMVC7378E The command cannot be executed because the array is not encrypted.

Explanation:

The array must be encrypted before running the command.

User response:

Encrypt the array and then reattempt the command.

CMMVC7379E System encryption cannot be disabled because an encrypted array already exists.

Explanation:

System encryption cannot be disabled while an encrypted array exists. To disable encryption, the encrypted array must be deleted, which will result in the loss of data.

User response:

To disable encryption, delete the encrypted array, and then reattempt the command. Contact IBM Support for assistance before performing this step.

CMMVC7380E The command cannot be executed because an encrypted array exists.

Explanation:

The command cannot be run because the array encryption cannot be disabled.

User response:

No response is possible. The command is not allowed in this context.

CMMVC7381E The rekey failed because the current encryption key was not found on the USB drive.

Explanation:

Explanation: The rekey operation could not be completed because the current encryption key was not found on the USB drive.

User response:

Cancel the failed rekey operation, restore the current encryption key file to the USB drive, and then reattempt the operation.

CMMVC7382E The rekey failed because the new encryption key was not found on the USB drive.

Explanation:

The rekey operation could not be completed because the new encryption key was not found on the USB drive.

User response:

Cancel the failed rekey operation, restore the new encryption key file to the USB drive, and then reattempt the operation.

CMMVC7383E The rekey failed because the proposed new encryption key could not be generated.

Explanation:

The rekey operation failed because the new encryption key could not be generated. The USB flash drive might be unusable.

User response

Cancel the failed rekey operation and replace the USB flash drive before you attempt a new rekey operation.

If the chencryption -usb newkey -key prepare command was issued, then the encryption key file might already exist on the USB flash drive.

Replace the USB flash drive with a blank USB flash drive and retry the command. Securely format or destroy the unusable USB flash drive.

CMMVC7384E The rekey operation failed because one of the drives failed to prepare for the rekey.

Explanation:

The rekey operation failed because the -key prepare option of the chencryption command failed on one of the drives.

User response:

Review the event log and resolve the corresponding event.

CMMVC7385E The rekey operation failed because one of the drives failed to commit to the rekey.

Explanation:

The rekey operation failed because the -key commit option to the chencryption command failed on one of the drives, causing the drive to fail to commit.

User response:

Review the event log and resolve the corresponding event.

CMMVC7386E The rekey operation failed because one of the drives failed to cancel the rekey.

Explanation:

The rekey operation failed because the -key cancel option to the chencryption command failed on one of the drives.

User response:

Review the event log and resolve the corresponding event.

CMMVC7387E The command cannot be initiated because the rekey is not in an expected state.

Explanation:

The command cannot be initiated because the rekey is not in an expected state.

User response

Issue the appropriate command based on the current rekey state.

A commit operation can only be performed when the rekey state is prepare or commit_failed.

A cancel operation can only be performed when the rekey state is prepare_complete, prepare_failed or cancel_failed.

CMMVC7388E Rebuild options are not supported for this array RAID level.

Explanation:

The command cannot be initiated because the rekey is not in an expected state.

User response:

Issue the command against a RAID 5 array. Do not target a RAID 0 array.

CMMVC7391E Specified drive is in the incorrect enclosure.

Explanation

An attempt was made to swap an array member for a spare. Arrays for this product must be contained within a single enclosure. The specified drive is in the wrong enclosure.

User response

Retry the command and specify a new array member that is in of the same enclosure as the rest of the array.

CMMVC7392E The enclosure is already managed by a different cluster.

Explanation

An enclosure cannot be managed by more than one cluster at a time.

User response

If you want to change the cluster that manages the enclosure, complete the following steps:

1. Log in to the cluster that is currently managing the enclosure.
2. Delete the array on the enclosure by using the management GUI or by running the **rmarray** command.
3. Stop managing the enclosure by using the management GUI or by running the **chenclosure -managed no** command.

If you do not have access to the cluster that is currently managing the enclosure, you can log on to the enclosure and run the **satask leavecluster -force** command. Using the **-force** parameter can lead to data loss if the enclosure is in use.

After you remove the enclosure from the management of the previous cluster, you can retry the original **chenclosure -managed yes** command.

CMMVC7393E The enclosure cannot be unmanaged as there is an array present.

Explanation

You can remove management from an expansion enclosure only when no arrays are configured.

User response

Remove the array from the enclosure by using the management GUI or by running the **rmarray** command. Then, retry the original command.

CMMVC7394W Encryption feature is being used without system license entitlement.

Explanation

An encryption license was not available for the command that was run. The command completed, but you must still obtain a valid license.

User response

Contact your support representative to obtain the necessary encryption license.

CMMVC7395E The command cannot be executed because the enclosure is not a part of the cluster.

Explanation

You tried to create an array with a flash enclosure that is not managed.

User response

Change the flash enclosure to a managed type by using the following command:

```
chenclosure -managed yes enclosureId
```

where *enclosureId* is the ID of the enclosure as displayed in the **lsenclosure** command. Then, retry the command.

CMMVC7396E The command failed because the target managed disk (MDisk) is in offline state.

Explanation

An MDisk cannot be added to a storage pool when that MDisk is offline.

User response

Make sure that you specified the correct MDisk. If so, make sure the specified MDisk is online and accessible before you retry the command.

CMMVC7399E The command cannot be run as the enclosure is not yet managed.

Explanation

This command requires the enclosure to be in the managed state.

User response

Manage the enclosure by using the management GUI or by running the **chenclosure -managed yes** command. Then, retry the original command.

CMMVC7402E The command has failed because the IP address is not valid.

Explanation

The command specified an IP address with an invalid format.

User response

Retry the command with a valid IPv4 or IPv6 address.

CMMVC7403E The command cannot be initiated because it is not supported for the specified enclosure type

Explanation

The specified enclosure was not the correct type for this command.

User response

Review the command documentation or specify an alternative enclosure.

CMMVC7404E The command cannot be initiated because it is not supported for the specified drive type

Explanation

The specified drive was not the correct type for this command.

For systems that support NVMe drives, the **chquorum** command is not supported on NVMe drives.

User response

Review the command documentation or specify an alternative drive.

For systems that support NVMe drives, specify a SAS drive or managed disk when you use the **chquorum** command.

CMMVC7405E The command cannot be initiated because it is not supported for the specified array type

Explanation

The specified array was not the correct type for this command.

User response

Review the command documentation or specify an alternative array.

CMMVC7406E The command failed because the requested volume size is too large. Reduce the array's reserved capacity to free space.

Explanation:

The **mkvdisk -size** and **chvdisk -size** commands cannot encroach on the array space that is reserved for performance enhancement.

User response

- Specify a smaller volume size.
- Reduce the amount of space in the array that is reserved to increase performance.

CMMVC7407E The array has insufficient free space to reserve for performance.

Explanation:

The array does not have sufficient free space reserved for performance.

User response

Complete one of the following tasks:

- Use the **charray -reservesize** command to reserve a size that is smaller than that of the array.
- Delete volumes to increase available space in the array.

CMMVC7408E The command has failed because one or more of the parameters entered is not valid for the specified enclosure type.

Explanation

Some parameters are only valid when used with certain types of enclosure.

User response

Review the command syntax for the type of enclosure specified or specify an alternative enclosure.

CMMVC7409E The command cannot be initiated because the port is not online.

Explanation:

chportip must be used on a port that is online.

User response:

Use **lsportip** to see the state of the port. If the state is listed as **offline**, the port is offline.

CMMVC7410E The command has failed because one or more of the parameters

entered is not valid for the specified drive type.

Explanation

Some parameters are only valid when used with certain types of drives.

User response

Review the command syntax for the type of drive specified or specify an alternative drive.

CMMVC7411E The command has failed because one or more of the parameters entered is not valid for the specified array type.

Explanation

Some parameters are only valid when used with a certain type of array.

User response

Review the command syntax for the type of array specified or specify an alternative array.

CMMVC8000E Cannot execute on an active node.

Explanation

This operation cannot be executed on an active node.

User response

Choose an inactive node, or deactivate the node before trying the operation again.

CMMVC8001E Cannot execute on a candidate node.

Explanation:

This operation cannot be executed on a candidate node.

User response

Choose another node and try the operation again.

CMMVC8002E Cannot execute on a service-state node.

Explanation:

This operation cannot be executed on a service-state node.

User response

Choose another node and try the operation again.

CMMVC8003E Cannot execute on a node in a cluster-recovery state.

Explanation

This operation cannot be executed on a node in a cluster-recovery state.

User response

Choose another node and try the operation again.

CMMVC8004E Cannot execute on a node with a location error.

Explanation:

You cannot process this operation on a node with a location error.

User response:

Fix the error or choose another node and try the operation again.

CMMVC8005E Cannot execute on a node displaying hardware errors.

Explanation:

You cannot execute this operation on a node displaying hardware errors.

User response:

Fix the errors or choose another node and try the operation again.

CMMVC8006E Cannot execute on a node displaying errors.

Explanation:

You cannot execute this operation on a node displaying errors.

User response:

Fix the errors or choose another node and try the operation again.

CMMVC8007E Cannot execute on a node which is charging.

Explanation

You cannot execute this operation on a node that is charging its batteries.

User response

Wait until the batteries have finished charging and try the operation again.

CMMVC8008E Command not supported on this hardware platform

Explanation

The command is not supported on this system or cannot be run on this node.

User response

Ensure that the correct service actions are being attempted for the hardware, and ensure that the appropriate command is run on the correct node, or choose another node and try the operation again.

CMMVC8009E Cannot execute on a node canister.**Explanation:**

You cannot execute this operation on a node canister.

User response

Choose an appropriate target and try the operation again.

CMMVC8010E Not from a USB stick.**Explanation:**

You cannot execute this operation from a USB stick.

User response

Change location to an appropriate place and try the operation again.

CMMVC8011E Version too high for this client.**Explanation:**

You cannot complete this operation during a manual update.

User response:

Wait until the manual update finishes and try the operation again.

CMMVC8012E The operation did not complete in the time allowed.**Explanation:**

The operation did not complete in the time allowed.

User response

Set the time allowed for operations to complete appropriately. Determine if another operation or error caused the problem.

CMMVC8013E Incompatible parameters set.**Explanation:**

Parameters provided are mutually exclusive.

User response

Set appropriate parameters and try the operation again.

CMMVC8014E Bad parameter value.**Explanation:**

This error occurs when a command is specified with an unparseable IP address, worldwide node name

(WWNN), or other unknown parameter value. This error can also occur when a specified password contains too few or too many characters. Passwords must contain more than 5 and fewer than 65 ASCII characters.

User response:

Retry the command, specifying appropriate parameters.

CMMVC8015E Failed.**Explanation:**

The enclosure midplane has a cluster ID set or the next cluster ID on the midplane is corrupt or invalid.

User response

Fix the problem and try the operation again.

CMMVC8016E Node would be clustered if not in service state.**Explanation:**

Cannot run because the node will be in cluster when it exits service.

User response

Fix the problem and try the operation again.

CMMVC8017E Info value not recognised.**Explanation:**

Info value not recognized.

User response

Use a valid info value and try the operation again.

CMMVC8018E Provided buffer was too small.**Explanation:**

Provided buffer was too small.

User response

Increase the buffer size.

CMMVC8019E Task could interrupt IO and force flag not set.**Explanation:**

Running on an active node could impact I/O.

User response

Wait until the node is inactive before performing this task.

CMMVC8020E Attempting to create cluster while there is a stored cluster ID.**Explanation:**

An attempt was made to create a cluster while the control enclosure or the node has a stored cluster ID.

User response

Change the cluster ID or chose a different control enclosure or node.

CMMVC8021E Invalid panel name.

Explanation:

Invalid panel name given in the parameter.

User response

Use a valid panel name.

CMMVC8022E New cluster created but node cannot leave service state.

Explanation:

New cluster created but node cannot leave service state. The battery might be charging or some other service task running.

User response

Wait until all service tasks complete.

CMMVC8023E Partner node is clustered.

Explanation:

Cannot execute because the partner node is clustered.

User response

Take the partner node out of the cluster, or choose a different node.

CMMVC8024E Gateway or subnet/prefix required.

Explanation:

A Gateway or subnet/prefix required.

User response

Use a Gateway or subnet/prefix.

CMMVC8025E DHCP Failed.

Explanation:

DHCP Failed.

User response

Try operation again.

CMMVC8026E No suitable donor.

Explanation:

No suitable donor.

User response

[User response needed].

CMMVC8027E T3 prepare failed.

Explanation:

T3 prepare failed.

User response

[User response needed].

CMMVC8028E T3 prepare incomplete.

Explanation:

T3 prepare not complete.

User response

[User response needed].

CMMVC8029E T3 execute failed.

Explanation:

T3 execute failed.

User response

[User response needed].

CMMVC8030E Another instance of this command is already running.

Explanation:

Cannot execute because another instance of this command is already running.

User response

Wait for the other instance of the command to complete.

CMMVC8031E file not found.

Explanation:

Required/provided file is not on the file system in the expected location.

User response

Locate the missing file.

CMMVC8032E The specific update package cannot be installed over the current version.

Explanation:

Cannot install this code over current version; cannot update to this version; code is already at this level.

User response

Make sure you are installing the right version.

CMMVC8033E Password reset disabled.**Explanation:**

The password reset function is disabled.

User response

Enable the password reset function or contact your system administrator.

CMMVC8034E A compulsory parameter is missing.**Explanation:**

Cannot execute because required parameter has not been provided.

User response

Provide the required parameter.

CMMVC8035E The service assistant CLI is not ready - try again.**Explanation:**

The Service CLI interface is not ready/running yet.

User response

Wait a few moments and try again.

CMMVC8036E No help available.**Explanation:**

There is no available help.

User response

Contact IBM Support.

CMMVC8037E A required parameter is missing.**Explanation:**

A required parameter is missing.

User response

Rerun the operation with the required parameter set.

CMMVC8038E Required parameters are missing.**Explanation:**

Required parameters are missing.

User response

Rerun the operation with the required parameters set.

CMMVC8039E The [%1] parameter is missing its associated arguments.**Explanation:**

The parameter is missing an argument.

User response

Rerun the operation with the required arguments for the parameter.

CMMVC8040E [%1] is not a supported parameter.**Explanation:**

The parameter is not supported.

User response

Rerun the operation using a supported parameter.

CMMVC8041E [%1] is not a valid command line option.**Explanation:**

The command given does not exist.

User response

Use an existing command.

CMMVC8042E Invalid or inconsistent arguments.**Explanation:**

Invalid or inconsistent arguments. For example, the argument at the end is not a recognized panel id.

User response

Use valid and consistent arguments.

CMMVC8043E This command can only be run by the superuser.**Explanation:**

Cannot execute because user is not superuser.

User response

Have a superuser run the command.

CMMVC8044E Command completed successfully.**Explanation:**

Command completed successfully. This message is only used within lscmdstatus.

User response

None.

CMMVC8045E Authentication failed.**Explanation:**

Authentication failed.

User response

[Need user response].

CMMVC8046E Partner node has lost cluster data.

Explanation:

Partner node has lost cluster data.

User response

[Need user response].

CMMVC8047E Not a valid ssh key.**Explanation:**

Argument is not a valid ssh key.

User response

Use a valid ssh key for the argument.

CMMVC8048E Invalid file permissions.**Explanation:**

Cannot execute the argument. The file has invalid file permissions.

User response

Set valid file permissions.

CMMVC8049E Invalid cluster name.**Explanation:**

User provided an invalid cluster name.

User response

Use a valid cluster name.

CMMVC8050E Files cannot be unpacked from the update package. The system must unpack them.**Explanation**

Possible causes are:

1. A bad boot drive or sector.
2. Full /upgrade, /tmp, or /upgrade.
3. An invalid package.

User response

1. Clear all dumps and retry the installation.
2. Reboot the node and retry the installation.

CMMVC8051E Utilities package installed.**Explanation:**

The utilities package installed successfully.

User response

None.

CMMVC8052E The signature of the utility package has failed verification.**Explanation**

This can be caused by the following issues:

1. The package has become corrupted.
2. The package is not a valid IBM utility.
3. The system clock on the node is long out-of-date and the package signature is too far into the future.

User response

1. Ensure that the installation package is complete and retry the installation.
2. Verify that the utility was provided by IBM support personnel.
3. Use chsystemtime Change the system clock to accurately reflect the date.

CMMVC8053E The specific update package cannot be installed on this hardware.**Explanation:**

The software is incompatible with the hardware level.

User response

Ensure that you have downloaded the appropriate package for the hardware you are updating.

CMMVC8054E The update failed as the package is missing files.**Explanation:**

The package can be missing files due to a bad upload.

User response:

Validate that the package was downloaded or uploaded properly and try to run the update again.

CMMVC8055E The command cannot be run because the node is busy.**Explanation:**

The node or enclosure can run only one task command at a time, or the firmware is being updated so the command cannot be run currently.

User response

Wait for the task to complete and run the command again.

CMMVC8056E An error occurred in communicating with the target node.**Explanation**

The error can be caused by:

1. A fault in one partner node is preventing another partner node from seeing it.

2. The Fibre Channel network is congested or faulty, and packages are failing to transfer.

User response

1. If you are using SAN connectivity, check your fabric to ensure that all the nodes in a cluster have clear paths to one another.
2. Ensure that the target node is online and does not have a hardware or location error (if it is Enclosure based).
3. Ensure that both the source and target nodes see each other in lsservicenodes. If they do not see each other, a path is missing.
4. If trying the first three steps does not correct the problem, work directly on the node in question rather than from the partner node. Log onto the target node's service assistant and run the operation locally.

CMMVC8057E **Files cannot be copied to a node which is not part of the source cluster.**

Explanation:

Files cannot be copied to a node which is not part of the source cluster using cpfiles.

User response

Choose a node that is part of the source cluster.

CMMVC8058E **Cannot create file, file already exists.**

Explanation:

The ssh key file you are trying to create already exists.

User response

None.

CMMVC8059E **The update package supplied cannot be installed using service state whilst maintaining the cluster configuration on this node. To maintain the cluster configuration on this node, this package can only be installed with applysoftware or pacedccu mode. This package can be installed in service state using the -ignore flag, however the cluster state will be destroyed and cluster configuration will be lost from the node.**

Explanation

A software update to this level cannot be issued when it uses service state without using the **-ignore** flag. The **-ignore** flag removes the cluster configuration from the node. If you want to maintain the cluster configuration, you must install the package by using the automated **applysoftware** command or by manual update.

Attention: Be careful when you use the **-ignore** flag. You might see adverse consequences to the data that is processed.

User response

Use the correct procedure to update the code package.

CMMVC8060E **DHCP fallback is not supported on this platform.**

Explanation:

You tried to set the service IP via DHCP with fallback enabled. This platform does not support the fallback option.

User response

Set the service IP via DHCP without fallback enabled. This product does not support the fallback option.

CMMVC8061E **The enclosure does not support setting a machine part number.**

Explanation:

Cannot execute because there is no -machinepartnum on this system.

User response

None.

CMMVC8062E **The machine type and model is not valid for this enclosure.**

Explanation:

The machine type and model is not valid for this enclosure.

User response

Use a valid machine type and model with the command.

CMMVC8063E **The machine part number is not valid for this enclosure.**

Explanation:

The machine part number is not valid for this enclosure.

User response

Use a valid machine part number with the command.

CMMVC8064E The machine part number and machine type and model are not valid for this enclosure.

Explanation:

The machine part number and machine type and model are not valid for this enclosure.

User response

Use a valid machine part number and machine type and model with the command.

CMMVC8065E An enclosure property has already been set and cannot be modified.

Explanation:

An enclosure property has already been set and cannot be modified. A valid VPD exists and will not be overwritten.

User response

If the machine serial number is not 00000000 or is not the same as the serial number stored on one of the boot drives, then the system board must be replaced again with a clean FRU that has a machine serial number of 00000000 stored on it. .

CMMVC8066E A new enclosure VPD field does not match the node copy.

Explanation:

A new enclosure VPD field does not match the node copy. An unexpected value was given.

User response

Rerun the command with the correct value in the enclosure VPD field.

CMMVC8070E The specified IP addresses are not in the same sub-network.

Explanation:

The IP address parameter values in satask.txt and cfgtask.txt that must be in the same sub-network are not all in the same sub-network. i.e. The bit wise AND of an IP address with the subnet mask is not the same as the bit wise AND of another IP address with the subnet mask.

User response

Check and correct the parameters in satask.txt and cfgtask.txt or use InitTool to create new valid satask.txt and cfgtask.txt files on the USB flash drive to start the initial setup of the system.

CMMVC8071E The specified IP address is already in use.

Explanation:

An arping of the IP address has received a reply from an IP host on the network that is already using this IP address from satask.txt.

User response

If you cannot stop the other IP host from using that IP address then allocate another IP address and use InitTool to create new valid satask.txt and cfgtask.txt files on the USB flash drive to start the initial setup of the system.

CMMVC8072E The above parameters are invalid or missing from cfgtask.txt.

Explanation:

The required parameters shown above this error message are invalid or missing from cfgtask.txt.

User response

Check and correct the parameters in cfgtask.txt or use InitTool to create new valid satask.txt and cfgtask.txt files on the USB flash drive to start the initial setup of the system.

CMMVC8085E The command failed because the node does not support technician port functionality.

Explanation

Some older models do not provide a technician port.

User response

To connect a workstation directly to a node without a technician port, connect the workstation using Ethernet port 1 or 2 and an IP address compatible with the system IP or service IP of the node. If the IP configuration of these ports is not known, use a USB flash drive inserted into the USB port of the node.

CMMVC8086E The command failed because the node already has a dedicated technician port.

Explanation

When a node has a dedicated technician port, it is not possible to configure another port as a technician port. The dedicated technician port is permanently enabled.

User response

If you need to connect a workstation directly to the node for maintenance, use the dedicated technician port.

CMMVC8087E The command failed because the file specified is a valid USVNID file but it is for a different node.

Explanation

An activation file was provided that is in the correct format but has an incorrect unique ID (obtained from the node during the installation process).

User response

Verify that the correct file was downloaded. You might need to repeat the steps that you took to generate this file, making sure that you use the correct node ID.

CMMVC8088E The command failed because the file specified is not a valid USVNID file.

Explanation

An activation file was provided that is in the wrong format.

User response

Verify that the correct file was downloaded. You might need to repeat the steps that you took to generate this file.

CMMVC8091E No upload in progress.

Explanation

An attempt was made to cancel an upload when no upload was in progress.

User response

Only active uploads can be canceled.

CMMVC8092E An error occurred in communicating with the remote server.

Explanation

An attempt was made to connect to the remote server through the **supportupload** or the **downloadsoftware** command. The connection was not completed.

User response

See the prerequisites for the **supportupload** or the **downloadsoftware** command. After you meet those conditions, retry the command.

CMMVC8093E No download in progress.

Explanation

An attempt was made to cancel a download when no download was in progress.

User response

Only active downloads can be canceled.

CMMVC8094E The command failed because the available space is inadequate for the download.

Explanation

An attempt was made to download files from the Fix Central server by using the **downloadsoftware** command. Not enough space was available for the download to complete.

User response

Remove unwanted files from the target system and retry the command.

CMMVC8095E The command failed because the target Ethernet port does not exist.

Explanation

Ethernet ports are numbered sequentially beginning with 1. The specified Ethernet port has a number that is larger than the total number of Ethernet ports on the system.

User response

Retry the command with a valid Ethernet port number. To display the available Ethernet ports, enter one of the following commands:

- **lsportip**
- **sainfo lsnodeip**
- **sainfo lsservicestatus**

CMMVC8096E The command failed because insufficient paths would exist for the IP connection between the nodes in the same IP discovery zone.

Explanation

An attempt was made to remove or change the IP address of a non-redundant connection. Removing or changing this address can cause the I/O group to lose redundancy, or can cause a degraded I/O group to become unavailable.

User response

Complete one of the following actions:

- Use the **satask chnodeip** command to add a node IP address to the non-redundant connection nodes in the same IP discovery zone. You can then retry the command.
- You can retry the command with the **-force** parameter. Use of this parameter can cause the I/O group to lose redundancy, or can cause a degraded I/O group to become unavailable. Because the **-force** parameter can have unforeseen consequences, it is typically used in test situations only.

CMMVC8097E	The command failed because a duplicate WWNN has been detected.
-------------------	---

Explanation

This error can occur if a duplicate worldwide node name (WWNN) is detected when you run the **chnodeip** command.

User response

Issue the **satask chvpcd -wwnn *WWNN*** command to change the duplicate WWNN. For more information about correcting duplicate WWNNs, see the documentation for node error [556](#).

CMMVC8098E	The command failed because the specified ethernet port is not an RDMA capable port.
-------------------	--

Explanation

This error occurs when an attempt is made to configure a port for Remote Direct Memory Access (RDMA) clustering, but the port does not support RDMA.

User response

Retry the command, specifying a port that supports RDMA.

CMMVC8099E	The command failed because the target Ethernet port is set to non default MTU value.
-------------------	---

Explanation

This error occurs when an attempt is made to configure a port for Remote Direct Memory Access (RDMA) clustering, but the MTU value of the port is not the default setting (1500).

User response

Use the **cfgportip** command to change the MTU value of the port to 1500, and then retry the command.

CMMVC8100E	Partner canister must be in candidate state before clustering.
-------------------	---

Explanation

Both node canisters must be in a candidate state before a cluster can be created in a control enclosure.

User response

Follow the service action to set the node canisters into a candidate state.

CMMVC8202E	To perform this task, a system board mismatch node error must be active.
-------------------	---

Explanation

This error occurs when an attempt is made to run the **chbootdrive -replacecanister** command but no mismatch between the boot drives and system board or canister can be detected.

User response

Use the **lsbootdrive** command to determine the current state of the boot drives. If all drives are online, no further action is required. If one or more drives are offline, use the **lsservicenodes** command to determine the active node error, and then follow the suggested procedure for that error.

CMMVC8203E	To perform this task, the number of boot drives present must be correct.
-------------------	---

Explanation

This error occurs when an incorrect number of boot drives are detected. The node canisters of a model AF7 control enclosure must have one boot disk. The node canisters of a model AF8 control enclosure must have two boot disks.

User response

Depending on the control enclosure, either attach the missing drive or remove the additional drive.

CMMVC8204E **To perform this task, the boot drive owners (actual_node_sn) must be the same.**

Explanation

This error occurs when the `actual_node_sn` values displayed by the **sainfo lsbootdrive** command do not match.

User response

The `actual_node_sn` values for both boot drives must match the canister serial number of the replaced canister. The serial number can be read from the sticker at the rear of the canister. Shut down the node, locate and install the missing boot drives, restart the node, and then run the command again.

CMMVC8206E **The command failed because the IP address is a reserved/special IP.**

Explanation

The IP address that was specified in the **chnodeip** command is special or reserved.

User response

Specify an IP address that is not special or reserved to configure a node.

CMMVC8207E **Backup data for the midplane is unavailable.**

Explanation

The midplane backup data is not available and must be entered manually.

User response

Provide the necessary information by using the following command:

```
satask chvpd -serial serial_number -mtm mtm
```

CMMVC8208E **The maximum number of discovery subnets are already configured on the node.**

Explanation

This error occurs if an attempt is made to configure more than 16 discovery subnets on a node.

User response

Remove an unused discovery subnet from the node, and then try the **addnodediscoverysubnet** command again.

CMMVC8209E **This subnet conflicts with one that is already configured on the node.**

Explanation

This error occurs if a discovery subnet is specified that overlaps with the address range of a discovery subnet that is already configured on the node.

User response

Retry the command, specifying a discovery subnet that does not overlap with the address ranges of any discovery subnets that are already configured on the node.

CMMVC8210E **This discovery subnet conflicts with the one reserved by IANA.**

Explanation

This error occurs when an attempt is made to specify a discovery subnet that uses an address range that is reserved by the Internet Assigned Numbers Authority (IANA).

User response

Retry the command, specifying a discovery subnet that does not use an address range that is reserved by the IANA.

CMMVC8211E **This subnet is too big to be set as a discovery subnet.**

Explanation

This error occurs when an attempt is made to specify a discovery subnet that includes more than 16 IP addresses. For an IPv4 address, this limit means that the network prefix must be 28 bits or larger.

User response

Retry the command, specifying a discovery subnet that includes 16 or fewer IP addresses.

CMMVC8212E **Node rescue is not supported in this platform.**

Explanation

This error can occur when an attempt is made to run the **satask rescuenode** command on a cloud node.

User response

Remove the cloud node from the system, reinstall the software on the cloud node, and then add the node back to the system.

CMMVC8216E **An insecure password was chosen.**

Explanation

This error can occur when an attempt is made to reset the password to the default password, or to use a password that does not comply with the password policy.

User response

Specify a password that complies with the password policy, and is not the default password.

CMMVC8261E **The command failed because the hardware configuration of the local cluster is not compatible with the software of a partnered cluster.**

Explanation:

The software version of the local cluster is newer than the software version of a partnered cluster, and additional hardware has been enabled that is not supported by the older software on the partnered cluster.

User response

Either update the software on the partnered cluster, turn off the new hardware on the local cluster, or stop the remote copy relationship with the remote cluster. Use the CLI command `chnodehardware -legacy` to disable hardware that is not supported by older software versions.

CMMVC8262E **Cannot remove the host from the specified I/O groups because host mappings exist in multiple I/O groups.**

Explanation:

If a host is defined in multiple I/O groups, and has access to a volume through all of those I/O groups, an attempt to remove the host from just one of those I/O groups always fails, even when the **-force** parameter is specified.

User response

Before you run the command again, complete one of the following steps:

- Modify the I/O group list so that the list includes all of the I/O groups that provide access to the volumes

2018 Spectrum Virtualize for SAN Volume Controller, FlashSystem, and Storwize Family: Command-Line Interface User's Guide

for the host. The host mappings are removed when the command runs.

- Modify the I/O group list so that the list excludes I/O groups that contain host mappings.

CMMVC8263E **The command failed because the volume is associated with a file system and your requested action can not be completed under your current user role.**

Explanation:

You are attempting to complete an action on a volume that is associated with a file system. However, you do not possess the required role for file system actions.

User response

Execute command through volume command.

CMMVC8264E **The command failed because the volume associated with a file system and only the real capacity of a compressed file system volume can be changed.**

Explanation:

You are attempting to resize a volume that is associated with a file system. However, you can only resize the real capacity of a file system volume if it is compressed.

User response

The command cannot be completed on this volume. It will only succeed with a volume that is not associated with a file system or a with a compressed file system volume.

CMMVC8265E **The action failed because the specified port is for management only.**

Explanation:

The action failed because the specified port is for management only.

User response

Try another port which is not marked as `management_only` in the output of `lsportip`.

CMMVC8266E **The action failed because the specified port is not installed.**

Explanation:

The action failed because the specified port is not installed.

User response

Use a port that is shown in the output of `lsportip` but which is not marked as `management_only`.

CMMVC8267E **The attempt to add the node to the system failed because the node is being manually updated. The system must be prepared for update by using the same package that is currently installed on the node that is being updated.**

Explanation

The manual update requires that you prepare the system for the update first. Manual update mode (the **-pacedccu** parameter) is in use and an attempt is being made to add a node to the system at a newer code level. However, one of the following situations occurred:

- The code level of the node that is being added requires that you prepare the system for update before you attempt to use the **addnode** command
- The system was prepared at a different code level than the version of software on the node that is being added

User response

Prepare the system for update with the same software version as the manual update node that you are adding. To do so, complete one of the following actions:

- Cancel the update and prepare the system with the correct package.
- Install a version of the code on the new node that matches the system version.

CMMVC8268E **The attempt to prepare the cluster for update has failed because the cluster has already been prepared with a different package level. The update must first be cancelled before reattempting the update.**

Explanation:

The user has prepared the cluster for update with one level package and then attempted to prepare the update with a different, higher level package or attempted to automate the update to a higher level after the cluster was prepared with a lower level package.

User response

The user must cancel the current update that is in progress and re-prepare with the desired update package.

CMMVC8269E **The attempt to prepare the cluster for update has failed because the previous update is in prepare_failed state. The previous update must first be aborted before reattempting the update.**

Explanation:

The current status of `lsupdate` reports the update as `prepare_failed`. This is an indication the user has already attempted to prepare an update, or started an update and in either scenario, the prepare has failed due to offline volumes. The cache flush has failed.

User response

The user needs to correct the error that caused the prepare to fail. Offline volumes are the most likely cause, also node resets might cause a prepare failure. Stop updates with prepare failures with the `applysoftware -abort` command, then reattempt the update.

CMMVC8270E **The applysoftware prepare timed out because an attempt to make the volume cache empty took too long. The command will be completed asynchronously. Use lsupdate to monitor the progress.**

Explanation:

The `applysoftware` prepare timed out because an attempt to make the volume cache empty took too long. The command will be completed asynchronously. Use `lsupdate` to monitor the progress. The state will be reported as prepared when successfully completed.

User response

Wait until the prepare completes and `lsupdate` reports prepared.

CMMVC8272E **Access iogrp parameter not valid when creating a file system volume.**

Explanation:

Access `iogrp` parameter not valid when creating a file system volume.

User response

Rerun `mkvdisk` without the `-accessiogrp` parameter or without the `-filesystem` parameter.

CMMVC8273E **Host cannot be removed as there is a volume that is accessible from multiple iogrps including one of the iogrps specified.**

Explanation:

If a volume is mapped to a host, it must be mapped in all of the iogrps in which it is accessible. The rmhostiogrp command fails if it would leave the system in this state.

User response

Use lshostvdiskmap to find the list of volumes that are mapped to the host in multiple iogrps. Then for each one either a) remove the host/volume mapping or b) remove the iorgp that the host is being removed from the volume's access iorgp set.

CMMVC8274E The entry in the event log cannot be fixed because the given sequence number is out of range.

Explanation:

The event log entry sequence number must be in the range 100 to 9,999,999 inclusive.

User response

Supply a valid event log entry sequence number in the range 100 to 9,999,999 inclusive.

CMMVC8275E An entry with the given sequence number cannot be found in the event log.

Explanation:

The fix request has failed because an entry with the given sequence number cannot be found in the event log.

User response

Supply a sequence number of an entry that exists in the event log.

CMMVC8276E The entry in the event log cannot be fixed because it has expired or is in the monitoring state.

Explanation:

The entry in the event log cannot be fixed because it has expired or is in the monitoring state.

User response

Expired and monitoring entries in the event log cannot be fixed.

CMMVC8277E The MTM format must be XXXX-YYY where X is a numeric value, and Y is numeric or upper case character.

Explanation:

The user has attempted to change the MTM but provided an incorrect format.

User response

Reissue the command with the MTM with the correct format. The format must be XXXX-YYY where XXXX are numeric values and YYY are alphanumeric characters. Any alphabetic characters must be upper case.

CMMVC8278E The volume is accessible through more than one I/O group, and the host being mapped to the volume does not support volumes being mapped from multiple I/O groups.

Explanation:

The volume is accessible through more than one I/O group, and the host being mapped to the volume does not support volumes being mapped from multiple I/O groups.

User response

Choose a different host or volume to map.

CMMVC8279E The volume is accessible through more than one I/O group, and the host being mapped to the volume has an iSCSI name. iSCSI hosts do not support volumes being mapped from multiple I/O groups.

Explanation:

The volume is accessible through more than one I/O group, and the host being mapped to the volume has an iSCSI name. iSCSI hosts do not support volumes being mapped from multiple I/O groups.

User response

Choose a different host or volume to map.

CMMVC8280E The host has at least one volume mapped which is accessible through more than one I/O group, and the port being added is from a host system which does not support volumes being mapped from multiple I/O groups.

Explanation

The host has at least one volume mapped which is accessible through more than one I/O group, and the port being added is from a host system which does not support volumes being mapped from multiple I/O groups.

Note: This error does not apply to release 7.6.0 and up.

User response

Choose a different port to add to the host.

CMMVC8281E **The host has at least one volume mapped which is accessible through more than one I/O group, and the port being added is from a host with an iscsi name. Iscsi hosts do not support volumes being mapped from multiple I/O groups.**

Explanation

The host has at least one volume mapped which is accessible through more than one I/O group, and the port being added is from a host with an iscsi name. Iscsi hosts do not support volumes being mapped from multiple I/O groups.

Note: This error does not apply to release 7.6.0 and up.

User response

Choose a different port to add to the host.

CMMVC8282E **At least one host mapped to the volume does not support volumes being mapped from multiple I/O groups.**

Explanation:

At least one host mapped to the volume does not support volumes being mapped from multiple I/O groups.

User response

Unmap the host which does not support access from multiple I/O groups.

CMMVC8283E **At least one host mapped to the volume has an iscsi name. Iscsi hosts do not support volumes being mapped from multiple I/O groups.**

Explanation:

At least one host mapped to the volume has an iscsi name. Iscsi hosts do not support volumes being mapped from multiple I/O groups.

User response

Unmap the host which does not support access from multiple I/O groups.

CMMVC8284E **The enclosure does not support setting a machine part number.**

Explanation

The user has attempted to set the machine part number on an enclosure that does not have a machine

part number as part of its VPD, for example a 2076-112.

User response

Check the node panel name and try again.

CMMVC8285E **The machine type and model is not valid for this enclosure.**

Explanation

The user has attempted to change an enclosure machine type and model (MTM) to one that is not valid for the enclosure hardware, or one that is valid for the enclosure hardware but is not valid for the enclosure machine part number.

User response

Check the MTM and try again.

CMMVC8286E **The machine part number is not valid for this enclosure.**

Explanation

The user has attempted to change an enclosure's part number to one that is not valid for the enclosure hardware, or one that is valid for the enclosure hardware but is not valid for the enclosure's machine part number.

User response

Check the machine part number and try again.

CMMVC8287E **The machine part number and machine type and model are not valid for this enclosure.**

Explanation

The user has attempted to change an enclosure machine part number and machine type and model (MTM) to values that are not valid for the enclosure hardware.

User response

Check the MTM and the machine part number and try again.

CMMVC8289E **A new enclosure VPD field does not match the node copy.**

Explanation

The user has attempted to modify the enclosure serial number, machine part number, or machine type and

model (MTM) for a replacement enclosure and the new value is not the value expected by the system.

User response

Check the service status view for the value the system is expecting and retry the command with the right value.

CMMVC8290E The action failed because the requested combination of notification settings is not permitted.

Explanation

The valid combinations of notification settings are info+warning+error and warning+error.

User response

Reissue the command using a valid combination of notification settings.

CMMVC8291E The command failed because it is not supported.

Explanation

The command entered is not supported on this platform. It might be supported on one of the other platforms and in the CLI help for those platforms.

User response

Check the command in the CLI guide; check the system is the intended one.

CMMVC8292E The command failed because a parameter is not supported.

Explanation

The user typed a command that is supported, but used a parameter that is not supported on this platform -- the parameter is supported on other platforms. For example the -mdisk parameter on the mkmdiskgrp command is not supported on this platform, but is supported on other platforms.

User response

Check the syntax in the CLI guide; check the system is the intended one.

CMMVC8293E The command failed because it is not supported for image-mode volumes.

Explanation

This error is returned by a migration command when issued against an image-mode volume on a platform that does not support migration for image-mode volumes.

User response

Perform these steps:

1. Use Volume Mirroring to change the volume's storage pool.
2. Add a volume copy in the desired storage pool.
3. Sync the volume.
4. Delete the first copy.

CMMVC8294E The command failed because the FlashCopy feature is not active and the maximum number of FlashCopy target volumes already exist.

Explanation

The user has already configured the maximum number of FlashCopy targets that are allowed without activating the FlashCopy licensed feature.

User response

Delete some FlashCopy targets or activate the FlashCopy licensed feature. Try the command again.

CMMVC8295E The command failed because a licensed feature is not activated.

Explanation

This command requires a licensed feature to be activated before it is used.

User response

Activate the licensed feature and try again.

CMMVC8296E The command failed because it is not supported for image-mode MDisks.

Explanation

This error is returned by the "remove mdisk" rmmdisk command when issued against an MDisk that is backing an image-mode volume on a platform that does not support migration for image-mode volumes.

User response

If the image-mode volume is not required then use rmvdisk to delete the volume. This deletes the MDisk

as well. If the user wants to migrate the image-mode volume's data to internal storage, do that using Volume Mirroring and then delete the image-mode volume copy.

CMMVC8297E The drive cannot be managed because it has become unreachable.

Explanation

This message occurs if the user tries to change the use of the drive too soon after the drive has been inserted or the enclosure has been connected for the first time. It can also occur because of a hardware fault or if the user tries to change the use of a drive that has been removed from the system but is already managed.

User response

Wait and try again. If this doesn't work after 10 minutes, replace the drive. A drive that has been removed can still have its use changed to unused.

CMMVC8298E The system cannot open the file.

Explanation:

The file specified after the -file option cannot be opened.

User response

Refer to the documentation for the update file to ensure that the update file is correct.

Obtain a new copy of the correct package file, copy it to the system, then run the command again.

CMMVC8299E The system ran out of temporary resource while opening the file.

Explanation:

The temporary directory used to unpack the file cannot be opened.

User response

In the unlikely event of this error occurring, schedule either a node reboot or a node rescue maintenance task.

Once the maintenance task completes and the node is online, try the command again.

CMMVC8300E The specified file cannot be used because it contains too many drive software images.

Explanation:

The drive package contains more files than can be unpacked.

User response

Use a new package file and try the command again.

CMMVC8301E The system cannot read drive software from the specified file because the file contains an invalid drive firmware version string.

Explanation:

The drive package has probably become corrupt or has been made incorrectly.

User response

Refer to the documentation for the update file to ensure that the update file is correct.

Obtain a new copy of the correct package file, copy it to the system, then run the command again.

CMMVC8302E The system cannot read drive software from the specified file.

Explanation:

An internal error has occurred extracting the drive firmware from the drive package.

User response

Refer to the documentation for the update file to ensure that the update file is correct.

Obtain a new copy of the correct package file, copy it to the system, then run the command again.

CMMVC8303E The system can only program the FPGA of one drive at a time.

Explanation:

More than one drive has been specified and the -type option has been set to fpga.

User response

Change the command to only specify a single drive ID because svctask applydrivesoftware -type fpga only supports one drive by one command.

CMMVC8304E The system cannot apply the task because an earlier drive update task is still in progress.

Explanation:

There is an existing svctask applydrivesoftware already running, and only one is allowed at a time.

User response

Try the command again when there is no drive update task in progress. Either use the lsdriveupgrade progress command to determine when the updates will be completed, or use svctask

applydrivesoftware -cancel to cancel the current drive update task.

CMMVC8305E The system cannot apply drive software to the specified drives because some of them are not online.

Explanation:

An svctask applydrivesoftware command has been issued, but some drives that have been specified are not online.

User response

Carry out problem determination to bring the drives online, then repeat the command. Alternatively, repeat the command but do not specify the drive ID of any drive that is not online.

CMMVC8306E Some of the specified drives are offline. The system cannot apply drive software to an offline drive, even if the -force option is specified.

Explanation:

An svctask applydrivesoftware command has been issued, but some drives that have been specified are offline.

User response

Ensure the drives specified are in the online or degraded state.

CMMVC8307E None of the drives can be scheduled for drive software upgrade.

Explanation:

None of the specified drives are in a suitable state to apply drive firmware updates.

User response

Ensure that the drive states meet all the requirements to permit drive software download before repeating the command.

CMMVC8309E The task cannot be initiated because some of the specified drives have an unsupported drive technology.

Explanation

The drive technology is the value of the **tech_type** field that is returned by the **svcinfo lsdrive** command. The following values are supported:

- tier0_flash

- tier1_flash
- tier_enterprise
- tier_nearline

Specifying a drive with any other technology type results in this error.

User response

Use the **lsdrive** command to determine which drives have an unsupported drive technology.

Repeat the command but do not include the drive ID of any drive with an unsupported drive type.

CMMVC8310E The task cannot be applied to unused drives when multiple drives are specified.

Explanation

Some of the specified drives cannot be upgraded since that are currently unused by the system.

User response

Repeat the command, but do not include the drive ID of any drive that is currently unused.

CMMVC8311E The system cannot open the file.

Explanation:

The file specified after the -file option cannot be opened.

User response

Refer to the documentation for the update file to ensure that the update file is correct.

Obtain a new copy of the correct package file, copy it to the system, then run the command again.

CMMVC8313E The specified file cannot be used because it contains too many drive software images.

Explanation:

The drive package contains more files than can be unpacked.

User response

Use a new package file and try the command again.

CMMVC8314E The system cannot read drive software from the specified file because the file contains an invalid drive firmware version string.

Explanation:

The drive package has probably become corrupt or has been made incorrectly.

User response

Refer to the documentation for the update file to ensure that the update file is correct.

Obtain a new copy of the correct package file, copy it to the system, then run the command again.

CMMVC8315E The system cannot read drive software from the specified file.

Explanation:

An internal error has occurred extracting the drive firmware from the drive package.

User response

Refer to the documentation for the update file to ensure that the update file is correct.

Obtain a new copy of the correct package file, copy it to the system, then run the command again.

CMMVC8316E The system can only program the FPGA of one drive at a time.

Explanation:

More than one drive has been specified and the -type option has been set to fpga.

User response

Change the command to only specify a single drive ID because svctask applydrivesoftware -type fpga only supports one drive by one command.

CMMVC8317E The system cannot apply the task because an earlier drive update task is still ongoing.

Explanation:

There is an existing svctask applydrivesoftware already running, and only one is allowed at a time.

User response

Try the command again when there is no drive update task in progress. Either use the lsdriveupgrade progress command to determine when the updates will be completed, or use svctask applydrivesoftware -cancel to cancel the current drive update task.

CMMVC8318E The system cannot apply drive software to the specified drives because some of them are not online.

Explanation:

An svctask applydrivesoftware command has been issued, but some drives that have been specified are not online.

User response

Carry out problem determination to bring the drives online, then repeat the command. Alternatively, repeat the command but do not specify the drive ID of any drive that is not online.

CMMVC8319E Some of the specified drives are offline. The system cannot apply drive software to an offline drive, even if the -force option is specified.

Explanation:

The svctask applydrivesoftware command was issued, but some specified drives are offline.

User response

Ensure that the specified drives are in either online or degraded state, then reissue the command.

CMMVC8320E None of the drives can be scheduled for drive software upgrade.

Explanation:

None of the specified drives are in a suitable state to apply drive firmware updates.

User response

Ensure that the drive states meet all the requirements to permit drive software download before repeating the command.

CMMVC8321E The '-all' or '-drive' option is required to specify the drive(s) you want to upgrade.

Explanation

An attempt was made to apply software to one or more drives without specifying a drive.

User response

Retry the **applydrivesoftware** command and this time specify either the **-all** option or the **-drive** option followed by one or more colon-separated drive IDs.

CMMVC8323E The task cannot be applied to unused drives when multiple drives are specified.

Explanation

Some of the specified drives cannot be upgraded because the drives are currently unused by the system.

User response

Repeat the command, but do not include the drive ID of any drive that is currently unused.

CMMVC8324E	There are no drive software upgrades scheduled.
-------------------	--

Explanation

The command is not ongoing while user input - cancel option.

User response

No action is required.

CMMVC8325E	None of the specified drives needed to be upgraded or downgraded.
-------------------	--

Explanation

Every requested drive firmware is up-to-date in default. If the package is old, or contains no newer images for the drives on the package, the command cannot pass the level check.

User response

Ensure the package is correct or use - allowreinstall or -allowdowngrade option, then repeat the command.

CMMVC8326E	The task cannot be initiated because the drive use changed.
-------------------	--

Explanation

The command is stopped if user change the use of the drive, because some drive may be changed to "unused" while the command is ongoing.

User response

Check the use of the drive that you specified on the command line. If it is still appropriate to upload new firmware to the drive, repeat the command.

CMMVC8327E	The -allowreinstall and -allowdowngrade options cannot be used with option -type fpga.
-------------------	---

Explanation

When we apply drivesoftware fpga type drives, we don't permit to reinstall or downgrade drives.

User response

To download drive FPGA software, repeat the command but ensure the -allowreinstall and -allowdowngrade options are omitted.

CMMVC8328E	No package file is specified or invalid package file name is used.
-------------------	---

Explanation

User input invalid package file name.

User response

Input right package file name, and repeat the command.

CMMVC8329E	The task cannot be initiated because downloading to one or more drives could cause volumes to go offline. Force is required.
-------------------	---

Explanation

With any drive software update, there is a risk that the drive might become unusable. For systems that support RAID0 arrays, if the drive is a member of a RAID0 array consider whether to introduce more redundancy to protect the data on that drive.

User response

If the drive is not a member of a RAID0 array, fix any errors in the event log that relate to the array. When the drive is a member of an array with sufficient redundancy, repeat the command. Alternatively, consider specifying the **-force** option.

CMMVC8330E	The %1 of %2 %3 in backup is %4; should be %5
-------------------	--

Explanation

The specified object has the specified property of the specified type with the specified incorrect value. The property most likely reflects the state of the object.

User response

Change the state to the required value, and resubmit the command.

CMMVC8331E	The command failed because at least one of the specified MDisks can only be used in image mode.
-------------------	--

Explanation

Image mode only MDisk is forbidden to be added into the storage pool.

User response

Do not include MDisk that can only be used in image mode in a storage pool.

CMMVC8332E No MDisk were removed from the storage pool because at least one of the specified MDisk can only be used in image mode.

Explanation

Cannot remove image mode only MDisk with this command.

User response

Use `rmvdisk` or `rmvdiskcopy` to remove the MDisk which could only be used in image mode.

CMMVC8333E The task failed because it is not supported for image mode only MDisk.

Explanation

Cannot migrate data away or to image mode only MDisk with this command.

User response

Use Volume Mirroring to migrate data from or to an image mode only MDisk.

CMMVC8335E Cannot change attribute for IP address in an active partnership.

Explanation

An attempt was made to change the attributes or the VLAN ID associated with an IP address where an active IP partnership was running on that address. You must stop the partnership before you change an attribute or a VLAN ID for this IP address.

User response

Stop the partnership by entering the `chpartnership -stop` command, then retry the original `cfgportip` command.

CMMVC8336E Site was not specified. Site must be specified because topology is stretched.

Explanation:

Site was not specified. Site must be specified because topology is stretched.

User response

Identify the site of the new node and resubmit the command with `-site` flag.

Or, change system topology.

Warning: Changing the topology will disable the DR feature.

CMMVC8337E Site specified not valid. System topology is stretched and the other member has been configured to the same site.

Explanation:

Site specified not valid. System topology is stretched and the other member has been configured to the same site.

User response

Identify a node in a different site to the existing node and resubmit.

Or, change system topology.

Warning: Changing the topology will disable the DR feature.

CMMVC8338E Site parameter is not supported until the current update completes.

Explanation:

Site parameter is not supported until the current update completes.

User response:

A node cannot be assigned to a site until the current update complete. Add the node without the `-site` parameter and configure sites after the update has completed.

CMMVC8339E Not supported on this system.

Explanation:

Not supported on this system.

User response:

The feature is not supported on this system. Wait for a later release.

CMMVC8340E Cannot modify site because system topology is stretched.

Explanation:

Cannot modify site because system topology is stretched.

User response

Set topology to standard then manipulate the site.

Warning: DR feature is not available when topology is standard.

CMMVC8341E **Site value is not valid. Can only specify site 1 or site 2.**

Explanation:

Site value is not valid. Can only specify site 1 or site 2.

User response:

Specify either site 1 or site 2.

CMMVC8342E **Cannot set stretched topology because some nodes do not have a configured site.**

Explanation:

Cannot set stretched topology because some nodes do not have a configured site.

User response:

Configure site for each node and then set topology.

CMMVC8343E **Cannot set stretched topology because some I/O groups have 2 nodes in the same site.**

Explanation:

Cannot set stretched topology because some I/O groups have 2 nodes in the same site.

User response:

Assign each node of the I/O group to a different site then set topology.

CMMVC8344E **Cannot change site because controller has one or more managed MDisk and the system topology is stretched or Hyperswap.**

Explanation

In stretched or HyperSwap system mode, it is not possible to change the site while the controller has one or more managed MDisk.

User response

Migrate or delete MDisk on the controller to make all MDisk unmanaged. Or, set the system topology to standard and then change site.

Note: The disaster recovery feature is not available with standard topology.

CMMVC8345E **Cannot change site because the controller is a SAS RAID Controller.**

Explanation

SAS RAID Controllers are not supported at this time.

User response

Use a FC connectivity controller.

CMMVC8346E **Cannot change quorum disk because there is already a quorum disk defined at that site, and the cluster topology is stretched or hyperswap.**

Explanation

Only one quorum disk is supported per site.

User response

Change either the identified current quorum disk ID, or a new quorum MDisk, so that they are not both in the same site.

Or, set the topology to standard.

Warning: Setting the topology to standard will disable the DR feature.

CMMVC8347E **Cannot modify rcauthmethod due to the presence of unstopped IP partnerships.**

Explanation

All IP partnerships must be stopped before rcauthmethod can be changed.

User response

Use chpartnership -stop to stop partnerships, then run the command again.

CMMVC8348E **Cannot modify chapsecret due to rcauthmethod set to chap and the presence of unstopped IP partnerships.**

Explanation

All IP partnerships must be stopped before rcauthmethod can be changed.

User response

Use chpartnership -stop to stop partnerships, then run the command again.

CMMVC8349E **The rc authentication method specified is not valid.**

Explanation

Value of rcauthmethod supplied is not 'chap' or 'none'.

User response

Correct the value of the parameter.

CMMVC8350E The command failed because the specified battery is offline.

Explanation

A command to adjust battery state cannot be completed because the specified battery is offline or has been removed.

User response

If the battery is offline but present, it is safe to remove without issuing a `chnodebattery -remove` command. To turn on the LED, the battery must be replaced and brought online.

CMMVC8351E The command has failed because the specified battery is not redundant.

Explanation

A request to prepare a battery for removal cannot be completed because the specified battery is not redundant.

User response

Remove the condition that is causing the lack of redundancy. Such conditions may include the partner battery being offline or not fully charged, or one of the boot drives being offline.

CMMVC8352E The task cannot be initiated because the download type is not valid.

Explanation

If `-type` is specified, only firmware or `fpga` is supported now.

User response

Check the input download type and repeat the command with a supported download type.

CMMVC8353E CHAP authentication failure

Explanation

The Partner Discovery has refused a discovery request because the CHAP secret that was specified is not correct.

User response

Correct CHAP secret must be provided.

CMMVC8354E Unreachable cluster IP address

Explanation

Incorrect partner cluster IP address parameter specified.

User response

Correct IP address of the cluster must be provided. IP address must be pingable.

CMMVC8355E Remote Copy port groups not configured or incorrectly configured.

Explanation

This error occurs when the administrator has not set up ethernet ports on any node of the local system with either remote copy port group 1 or 2. In addition, they may have been failed over or are offline.

User response

The administrator must execute the `cfgportip` CLI to configure one or more IP addresses on any one of the local nodes with remote copy port groups 1 or 2.

CMMVC8356E Remote Copy port groups not configured or incorrectly configured.

Explanation

This error occurs when the administrator attempts to set up more than one partnership of type IPv4 or IPv6.

User response

No action possible. The only option is to remove the existing partnership and create a new partnership.

CMMVC8357E Maximum number of allowed partnerships exceeded.

Explanation

This error occurs when the administrator attempts to set up more than 3 partnerships. A maximum of 3 FC partnerships, or 2 FC and 1 IP partnerships, can exist.

User response

No action possible. The only option is to remove one of the existing partnerships and create a new partnership.

CMMVC8358E No local cluster IPs for the partnership type configured.

Explanation

This error occurs when the administrator tries to create a partnership of type IPv4, but has not configured any IPv4 type cluster IPs on the local cluster. The same error is seen if the administrator tries to create a partnership of type IPv6, but has not configured any IPv6 type cluster IPs on the local cluster.

User response

The administrator must execute the `cfgportip` CLI to configure the local IP address depending on the type of IP partnership which is to be created.

CMMVC8359E Partner already exists in candidate list. Cannot create partnership.

Explanation

This error is seen when an attempt is made to create an IP partnership with a remote cluster that already appears in the candidate list displayed by the `lspartnershipcandidate` CLI.

User response

In this scenario, an FC link exists between the clusters. The administrator must run CLI `mkfcpartnership` to create partnership.

CMMVC8360E Specified partner cluster IP address is used on local cluster. Cannot create partnership.

Explanation

This error is seen when the administrator specifies a local IP address as the remote cluster IP address.

User response

A local IP address cannot be used to create an IP partnership. A remote IP address must be specified.

CMMVC8361E All IP addresses of the partnership type are either down or not configured.

Explanation

This error occurs when partner discovery is not reporting any matching remote ports. Example: The partnership type is IPv4, but all ethernet ports on the partner cluster are configured with IPv6 types (or vice versa). This can also happen when the partnership type is IPv4, but all IPv4 addresses configured on the partner cluster are offline.

User response

The administrator must specify the correct partnership type. This depends on the type of IP addresses configured on the remote cluster.

CMMVC8362E The action failed because the cluster ID is not valid.

Explanation

Partnership creation failed because the specified remote cluster ID is not valid.

User response

In case of CLI `mkfcpartnership`, the administrator should run CLI `lspartnershipcandidate` to check correct cluster id/name. In case of CLI `mkippartnership`, the administrator only specifies the IP address and clusterid is discovered. If this error occurs for `mkippartnership`, contact support.

CMMVC8363E The remote cluster partnership was not created because it already exists.

Explanation

This error occurs when an attempt is made to create a partnership with a cluster that is already in a partnership.

User response

No action. A partnership cannot be created with a cluster that is already in a partnership.

CMMVC8364E Unsupported partnership type specified.

Explanation

This error occurs when the administrator specifies an unsupported type of partnership type for CLI `chpartnership`.

User response

The administrator must look for a possible option in CLI help and specify the partnership type accordingly.

CMMVC8365E Cannot change parameter if partnership is not in stopped state.

Explanation

This error occurs when the administrator tries to modify partnership parameters without stopping the partnership.

User response

Administrator must run command `chpartnership -stop clusterid/name`

CMMVC8366E Incorrect remote cluster IP specified.

Explanation

This error occurs when the administrator running `chpartnership` specifies the type as IPv4, but specifies an IPv6 address value (or vice versa).

User response

Specify an IP address that is valid for the partnership type.

CMMVC8367E Incorrect operation of FC partnership.

Explanation

While running `chpartnership`, the CLI administrator specifies option `-clusterip`, `-chapsecret`, or `-nochapsecret` for FC partnership.

User response

No action. Options `-clusterip`, `-chapsecret`, and `-nochapsecret` are not valid for FC partnership

CMMVC8368E Cannot set or reset attributes for unconfigured ports.

Explanation

An attempt was made to complete one of the following actions when the corresponding IP address is not assigned:

- Change the attributes of a port.
- Add or remove the VLAN ID of a port.

User response

Configure the port by using the **`cfgportip`** command and specifying the missing IP address. You can change the port attributes, or add or remove the VLAN ID, as part of this same command, or make the changes in a separate **`cfgportip`** command.

CMMVC8369E The action failed because the cluster ID is not valid.

Explanation

User has entered wrong cluster ID.

User response

User must enter correct cluster ID.

CMMVC8370E The remote cluster partnership was not created because it already exists.

Explanation

An attempt was made to create a partnership with a cluster that is already in a partnership.

User response

No action. A partnership cannot be created with a cluster that is already in a partnership.

CMMVC8371E Unable to setup partnership due to partnership type mismatch.

Explanation

This error occurs when the partnership types of local and remote systems don't match. Example: The partnership type specified on the remote system `mkippartnership` CLI invocation is done with IPv6, but the corresponding invocation on the local system is done with IPv4.

User response

Specify the same partnership type on both clusters.

CMMVC8372E Unable to set up Remote Copy data paths with partner due to unavailability of matching Remote Copy port groups.

Explanation

This error occurs when the partner returns Remote Copy configuration information that doesn't have matching Remote Copy port group IDs. This error could also occur in cases where matching local or remote ports are offline (link state is inactive), failed over to the partner node. Example, The local system has Remote Copy port group ID set to 1 while the partner has Remote Copy port group ID set to 2.

User response

Both clusters should have the same Remote Copy group port ID.

CMMVC8373E Easy Tier is active without a license for each enclosure.

Explanation

Easy Tier must not be active without a license for each enclosure.

User response

Ensure that a license exists for each enclosure.

CMMVC8374E The command failed because the source volume has pinned data.

Explanation

A FlashCopy mapping can only be started if there is not any pinned data on the source volume.

User response

Investigate why the source volume is offline. Fix the error and bring the volume back online. Try the command again.

CMMVC8375E The command failed because the volume has pinned data.

Explanation

The command cannot be completed because of pinned data on the volume.

User response

Investigate why the volume is offline. Fix the error and bring the volume back online. Try the command again.

CMMVC8376E Cannot change quorum disk because there is already a quorum disk defined at that site, and the cluster topology is stretched or hyperswap.

Explanation

In the stretched or Hyperswap system, every quorum disk should have a valid site to ensure there is only one quorum per site.

User response

Find an MDisk with a valid site without any other quorum disks existing in this site.

CMMVC8377E Cannot change the site for a quorum drive.

Explanation

In stretched system mode, drives as a quorum disk without a valid site are not supported.

User response

Find an MDisk with a valid site without any other quorum disks existing in this site.

CMMVC8378E Cannot modify cluster IP due to the presence of unstopped IP partnerships.

Explanation

This error will display when the administrator is trying to change a clusterip and there is an active IP partnership on the cluster.

User response

Once the Administrator stops the IP partnership, the cluster IP can be changed.

CMMVC8379E Partner state is stopped.

Explanation

This error occurs when creating an IP partnership with a remote cluster and the remote cluster partnership is partially_configured_local_stopped.

User response

Run chpartnership -start <Cluster ID> on the remote cluster.

CMMVC8380E Partner software version mismatch.

Explanation

This error occurs when an attempt is made to create a partnership with nodes that have incompatible versions of system software.

User response

None. A compatible software version is required.

CMMVC8381E The task cannot be cancelled as it has completed all drive downloads.

Explanation

After the multiple drive download task has completed, there is a 270 second delay. It is not necessary to cancel the task if it was performed within this period of time.

User response

Wait 270 seconds before trying the command again.

CMMVC8382E The system cannot apply the task because a delay has been imposed between commands. (About 270 seconds)

Explanation

When a previous applydrivesoftware task is completed, a 270 second delay is imposed between each command. This error message will appear if a new task is attempted during this waiting period.

User response

Wait 270 seconds before trying the command again.

CMMVC8383E System layer mismatch.

Explanation

This error occurs when creating an IP partnership between two clusters when both clusters in a different layer.

User response

The administrator should change the cluster layer so that they are the same. To do this, use command - svctask chsystem -layer<storage/replication>.

CMMVC8384E The command has failed because the specified fan module is offline.

Explanation

A command to adjust the fan module state can not be completed because the fan module specified is offline or has been removed.

User response

The offline fan module triggers a fan module replacement dmp. This procedure should be followed to replace the broken or missing fan module with a functional unit.

Note: Will be returned by chenclosurefanmodule if used on a fan module that has a current state of offline.

CMMVC8386E Sync operation not possible.

Explanation

Node boot drive sync operation is not possible.

User response

Check the can_sync field on the lsnodebootdrive view. can_sync will be false if the drives are already in sync or when there are certain boot drive errors active

(unsupported drive, wrong node, invalid drive contents).

In the event that drives are already in sync, do nothing.

If there are boot drive errors active, resolve the drive error before attempting to sync.

CMMVC8387E Partner cluster ID mismatch.

Explanation

The discovery of the partner cluster returned a cluster ID that was different than the ID that the partnership was working with.

User response

This error occurs in two scenarios:

- An attempt was made to run the **chpartnership** command where a remote cluster IP address was specified that is not part of the current partnership. In this case, retry the command with a valid cluster IP address.
- A T3 or T4 recovery on the remote cluster has changed the remote cluster ID. In this case, you must remove and re-create the IP partnerships and relationships:
 1. Stop the remote copy relationship by using the **stoprcrelationship** command.
 2. Delete the remote copy relationship by using the **rmrcrelationship** command.
 3. Delete the partnership by using the **rmpartnership** command.
 4. Recreate the partnership by using the **mkippartnership** or the **mkfcpartnership** command.

CMMVC8389E [-size] is not a supported parameter for the specified mdiskgrp.

Explanation

Cannot change the size of a parent pool.

User response

Only the chmdiskgrp -size command can be used to change the size of a child pool.

CMMVC8390E Cannot set *easy_tier_option* for child storage pool, the value must be same as parent storage pool's easy tier setting.

Explanation

You cannot change the Easy Tier setting of a child storage pool.

User response

If you specified the wrong storage pool, retry the command using the correct storage pool.

If you want to change the Easy Tier setting of a parent pool, use the **chmdiskgrp -easytier easy_tier_option** command.

CMMVC8412E Cannot add mdisks to a child pool.

Explanation

The `mdisk_group_id/_name` specified in `addmisk` command must be a parent pool.

This error is reported from the CLI `addmisk` command.

User response

Specify a parent pool in the `addmisk` command.

CMMVC8415E The command cannot be initiated because the maximum supported number of drives already exists.

Explanation

On Storwize V5000 family systems, an I/O group cannot manage more than 504 drives. Other systems cannot manage more than 4,096 drives.

User response

Remove any unused drives and try again.

CMMVC8423E The command failed because the storage pool size is not a multiple of extent size.

Explanation

The child pool size must be a multiple of its extent size. For example, if the extent size is 256 MB, legal values for the storage pool size include 256 MB, 512 MB, 768 MB, and so on.

User response

Retry the command and specify a legal value for the storage pool size.

CMMVC8424E The command failed because the source or target storage pool is a child storage pool, and source and target are in different parent storage pools.

Explanation

An attempt was made to run a **migratevdisk** command that specified an invalid target **mdiskgrp** (child pool) parameter. Source and target storage pools must have the same parent storage pool.

User response

Retry the command and specify a valid target.

CMMVC8425E The command failed because the storage pool has child storage pools.

Explanation

An attempt was made to delete a parent storage pool that has child storage pools. This action is not permitted. To see how many child pools are associated with the parent, run the **lsmdiskgrp** command and look at the **child_mdisk_grp_count** field.

User response

To delete the parent storage pool, first remove all child storage pools by using the **rmmdiskgrp** command, then try again to remove the parent.

CMMVC8427E The command failed because the child storage pool can not be shrunk below its used capacity.

Explanation

The command failed because the child storage pool cannot shrink below its used capacity.

This error is reported from `chmdiskgrp -size new_size`.

User response

Specify a new size that is larger than the used capacity of the storage pool.

CMMVC8452E The command failed because the specified parent mdiskgrp is a child pool.

Explanation

The command failed because the child pool can not be shrunk below its used capacity.

This error is reported from `chmdiskgrp -size <new size>`.

User response

Specify a new size larger than its used capacity.

CMMVC8455E The command cannot be initiated because the maximum supported number of drives already exists.

Explanation

This error occurs when an attempt is made to manage more than the maximum number of supported drives. On Storwize V5000 family systems, an I/O group cannot manage more than 504 drives. Other systems cannot manage more than 4,096 drives.

User response

Remove any unused drives, and try again.

CMMVC8456E At least one drive on the enclosure cannot find drive update package.

Explanation

While updating the drives on the enclosure, the CLI returns this error if the drive update package filename is formatted incorrectly. Correct filename format: `mdisksw.product_id.firmware.fw_level.img`

User response

Check the .img file name in the .gpf file and retry the command.

CMMVC8457E The mapping cannot be removed because the volume being unmapped has received I/O within the defined volume protection period.

Explanation:

If volume protection is enabled, and the volume being unmapped has received I/O within the defined volume protection time period, then the command will fail.

User response:

Ensure no host I/O is being sent to the volume and ensure you have waited for the defined volume protection time period or disable volume protection.

CMMVC8458E The volume cannot be removed because the volume has received I/O within the defined volume protection period.

Explanation

If volume protection is enabled, and the volume has received I/O within the defined volume protection time period, then the command will fail.

This behaviour is not changed by the volume being mapped/unmapped.

The force flag does not affect this policing behaviour. For example, the force flag does not override the policing.

User response:

Ensure no host I/O is being sent to the volume and ensure you have waited for the defined volume protection time period or disable volume protection.

CMMVC8459E The volume cannot be removed because the volume has received I/O within the defined volume protection period.

Explanation

If the last volume copy is being deleted, volume protection is enabled, and the volume being deleted has received I/O within the defined volume protection time period, then the command will fail.

This behaviour is not changed by the volume being mapped/unmapped.

Deleting one (of two) volume copies is not affected.

The force flag does not affect this policing behaviour. For example, the force flag does not override the policing.

User response:

Ensure no host I/O is being sent to the volume and ensure you have waited for the defined volume protection time period or disable volume protection.

CMMVC8460E The storage pool cannot be deleted because at least one volume in the pool has received I/O within the defined volume protection period.

Explanation

If volume protection is enabled, and any volume in the pool being deleted has received I/O within the defined volume protection time period, then the command will be failed.

This behaviour is not affected by the force flag (the command would already be failed if there are any mdisks in the pool being deleted and the force flag was not used). For example, The force flag does not override the policing.

User response:

Ensure no host I/O is being sent to volumes in the storage pool and ensure you have waited for the defined volume protection time period or disable volume protection.

CMMVC8461E The host cannot be removed because the host being deleted is mapped to volumes which have

received I/O within the defined volume protection period.

Explanation

If volume protection is enabled, and the host being deleted is mapped to any volume which has received I/O within the defined volume protection time period, then the command will fail.

This behaviour is not affected by the force flag (the force flag deletes the host even if it has any vdisk mappings). For example, the force flag does not override the policing.

If multiple hosts are mapped to the same volume, then the command will be allowed if the host that is being removed is already 'offline'. The protection will still prevent the last host being removed regardless of whether it is online or not (This is an effort to improve the policing behaviour for clustered hosts).

User response:

Ensure no host I/O is being sent to the volumes mapped to the host and ensure you have waited for the defined volume protection time period or disable volume protection.

CMMVC8462E The host I/O group cannot be removed because at least one volume in the I/O group(s) being removed from the host has received I/O within the defined volume protection period.

Explanation

If volume protection is enabled, and any volumes mapped to the host in the I/O group being removed from the host have received I/O within the defined volume protection time period, then the command will fail.

This behaviour is not affected by the force flag (the force flag deletes the host from I/O groups, even if it has any vdisk mappings in those I/O groups). For example, the force flag does not override the policing.

The same behaviour as rmhost, the policing will allow the I/O group if the host is already offline and at least one other host is mapped to the volume. It does not allow the io group to be removed if the host is the only host mapped to the volume and the volume is busy.

User response:

Ensure no host I/O is being sent to the affected volumes and ensure they have waited for the defined volume protection time period or disable volume protection.

CMMVC8463E The port cannot be removed because the host is mapped to at least one volume which have

received I/O within the defined volume protection period and the port is the last port associated with the host.

Explanation

If volume protection is enabled and the host port being deleted is the last port for a host mapped to any volume which has received I/O within the defined volume protection time period, the command will fail.

The same behavior applies for **rmhost**: the policing will allow the last host port to be removed if the host is already offline and there is another host mapped to the volume.

User response:

Ensure no host I/O is being sent to the volumes and ensure you have waited for the defined volume protection time period or disable volume protection.

CMMVC8469E The node cannot be added because it does not meet minimum hardware requirements.

Explanation:

An attempt was made to add a node to the system that does not have enough cache RAM (memory) installed to run the current level of code.

User response

Either choose a different node to add, or upgrade the cache RAM (memory) on this node.

CMMVC8470E The system update cannot be completed because it is not required.

Explanation:

The user is attempting to complete a system update. The action is not permitted because the system is not in a state where this is required.

User response

None - the command is not appropriate for the system.

CMMVC8471E The system update cannot be resumed because it is not stalled.

Explanation:

The user is trying to resume a system update. The system update is not in the 'stalled' state so cannot be resumed.

User response

No further action is required.

CMMVC8472E The action cannot be performed because paced update is not in progress.

Explanation:

The user is requesting that the next node in the system be updated as part of a paced system update. The system is not performing a paced update.

User response

No further action is required.

CMMVC8473E The next node cannot be updated because it is not ready for update.

Explanation:

The user is requesting that the next node in the system be updated as part of a paced system update. The system has not finished updating the current node yet and is not ready to start updating another node.

User response

Wait until the current node update has completed and the next node is ready.

CMMVC8474E The node cannot be updated because it would cause VDisks to go offline.

Explanation:

You are requesting that the next node in the system be updated as part of a paced system update. If this node is updated then some volumes will temporarily go offline.

User response

Either address the issue causing the volumes not to be redundant, or resubmit the command using the -force option. If the -force option is used then some volumes will temporarily go offline.

CMMVC8475E The node cannot be updated because it is offline.

Explanation:

You are requesting that the next node in the system be updated as part of a paced system update. The node cannot be updated because it is offline.

User response

Either delete the node from the system or perform service actions to bring it back online.

CMMVC8476E The node cannot be added because it would cause a paced update but the system has not completed its current update.

Explanation:

You are trying to add a node that has been configured to perform a paced update. A system update is currently in progress and it is not a suitable time to begin a paced update.

User response

Wait until the system update has completed, then add the node again.

CMMVC8477E The command failed because firmware applicable to a drive was not found in the package.

Explanation

While updating drives on the enclosure, the CLI returns this error if an incorrect format was used for the file name of the drive update package.

The correct file name format is:

```
mdisksw.product_id.firmware.fw_level.img
```

User response

Check the .img file name in the .gpf file and retry the command.

CMMVC8478E The mapping cannot be removed because the volume being unmapped has received I/O within the defined volume protection period.

Explanation

Volume protection is enabled, but the volume being unmapped has received I/O recently, within the defined volume protection time period, so the unmapping command fails. Receiving I/O generally indicates that a volume is in use.

User response

1. Ensure that this volume is intended to be unmapped. If you selected the wrong volume, repeat the unmapping command with the correct volume.
2. To unmap this volume, ensure that no host I/O is sent to the volume, wait the time specified in the `vdisk_protection_time` field in the **lssystem** command since the last I/O was received, then retry the unmapping command.
3. To disable volume protection and its warnings, disable the `vdisk_protection-enabled` field in the **chsystem** command.

CMMVC8479E The volume cannot be removed because the volume has received

I/O within the defined volume protection period.

Explanation

If volume protection is enabled and an attempt to delete the last volume copy occurs within the defined volume protection time period after the volume received I/O, the volume removal command fails. This policing behavior protects I/O integrity.

This policing behavior:

- Is not affected by the volume being mapped or unmapped
- Does not occur when deleting one of two volume copies
- Is not overridden by using the **force** flag

User response

1. Ensure that you intend to unmap the volume. If you selected the wrong volume, repeat the command with the correct volume.
2. To unmap the volume, ensure that no host I/O is sent to the volume, wait the time that is specified in the `vdisk_protection_time` field in the **lssystem** command, then retry the volume removal command.
3. Alternatively, to disable volume protection warnings and behavior, disable the `vdisk_protection-enabled` field using the **chsystem** command, then retry the volume removal command.

CMMVC8481E **The storage pool cannot be deleted because at least one volume in the pool has received I/O within the defined volume protection period.**

Explanation

If volume protection is enabled, and any volume in the storage pool being deleted received I/O within the defined volume protection time period, the storage pool deletion command fails. This is a policing behavior to protect I/O integrity.

This policing behavior is not overridden by the **force** flag.

User response

1. Ensure that no volumes are in use in the pool. If you selected the wrong pool, repeat the command with the correct pool.
2. To unmap all volumes in the pool, ensure that no host I/O is sent to any volume in the pool, wait the

time that is specified in the `vdisk_protection_time` field in the **lssystem** command, then retry the storage pool deletion command.

3. Alternatively, to disable volume protection warnings and behavior, disable the `vdisk_protection-enabled` field using the **chsystem** command, then retry the storage pool deletion command.

CMMVC8482E **The host cannot be removed because the host being deleted is mapped to volumes which have received I/O within the defined volume protection period.**

Explanation

If volume protection is enabled, and the host being deleted is mapped to any volume that has received I/O within the defined volume protection time period, the host deletion command fails. This policing behavior protects I/O integrity.

This policing behavior:

- Does not occur when multiple hosts are mapped to the same volume, and the host being removed is already offline
- Is not overridden by using the **force** flag
- Prevents the last host being removed regardless of whether the host is online or not, which improves the policing behaviour for clustered hosts

User response

1. Ensure that you intend to remove the host. If you selected the wrong host, repeat the command with the correct host.
2. To remove the host, ensure that no host I/O is sent to any volume mapped to the host, wait the time that is specified in the `vdisk_protection_time` field in the **lssystem** command, then retry the host removal command.
3. Alternatively, to disable volume protection warnings and behavior, disable the `vdisk_protection-enabled` field using the **chsystem** command, then retry the host removal command.

CMMVC8483E **The host I/O group cannot be removed because at least one volume in the I/O group(s) being removed from the host has received I/O within the defined volume protection period.**

Explanation

If volume protection is enabled, but any volume mapped to the host in the removal candidate I/O group has received I/O recently (within the defined volume protection time period), the host I/O group removal command, **rmhostiogrp**, fails.

This behavior is not affected by the **force** parameter of the command. The force parameter deletes from a host the I/O groups that have volume mappings. The force parameter does not override the volume protection policing.

Removing a host I/O group behaves the same way as does removing a host in that the policing behavior allows the removal of an I/O group if the host is offline, and if one other host is mapped to the volume. The policing policy does not allow removing the I/O group if the host is the only host mapped to the volume and the volume is busy.

User response

1. Ensure that the host I/O group is intended to be unmapped. If you selected the wrong host I/O group, repeat the removal command with the correct host I/O group.
2. To unmap the volumes in the host I/O group and remove the I/O group, ensure that no host I/O is sent to the volumes, wait the time specified in the `vdisk_protection_time` field in the **lssystem** command since the last I/O was received, then retry the host I/O group removal command.
3. To disable volume protection and its warnings, disable the `vdisk_protection-enabled` field in the **chsystem** command.

CMMVC8484E **The port cannot be removed because the host is mapped to at least one volume which have received I/O within the defined volume protection period and the port is the last port associated with the host.**

Explanation

If volume protection is enabled, but the host port is the last port for a host mapped to any volume that has received I/O recently (within the defined volume protection time period), the **rmhostport** command fails.

The **rmhostport** command shares a similar behavior with the **rmhost** and the **rmhostiogrp** commands: volume protection policing allows removal of the last host port if the host is already offline and there is another host mapped to the volume. The policing policy does not allow removing the host port if the host

is the only host mapped to the volume and the volume is busy.

This behavior is not affected by the force parameter of the command.

User response

1. Ensure that the host port is intended to be removed. If you selected the wrong host port, repeat the removal command with the correct host port.
2. To unmap the volumes in the host I/O group and remove the host port, ensure that no host I/O is sent to the volumes, wait the time specified in the `vdisk_protection_time` field in the **lssystem** command since the last I/O was received, then retry the host port removal command.
3. To disable volume protection and its warnings, disable the `vdisk_protection-enabled` field in the **chsystem** command.

CMMVC8485E **The command cannot be initiated because the drive that you have specified has not been formatted with the correct protection information scheme.**

Explanation:

The drive has not been formatted to the correct protection information scheme (Type 2), so initialization cannot be performed. This usually implies a process step has been missed during the manufacturing of the drive.

User response:

If you are confident that you have no data on the drive, use `chdrive -task format <drive_id>` to reformat the drive to the correct protection information scheme. Then, retry the command.

CMMVC8518E **The command failed because image-mode volumes are not supported in child storage pools.**

Explanation

You cannot create an image mode volume from the child pools.

This error is reported by the **mkvdisk -mode image** command.

User response

Change the volume mode to **striped**.

CMMVC8519E **The command failed because sequential-mode volumes are not supported in child storage pools.**

Explanation

You cannot create a sequential mode volume from the child pools.

This error is reported by the **mkvdisk -mode seq** command.

User response

Change the volume mode to **striped**.

CMMVC8523E The command failed because the specified storage pool is a child storage pool.

Explanation

This error is reported by the **mkmdiskgrp -parentmdiskgrp** command. The **parentmdiskgrp** parameter must identify a parent storage pool. You cannot create a child pool from another child pool.

User response

Specify a parent storage pool for the **-parentmdiskgrp** parameter.

CMMVC8525E The command failed because mdisks cannot be added to a child storage pool.

Explanation

The **mdisk_group_id** or **mdisk_group_name** that was specified in the **addmdisk** command must be a parent pool.

User response

Specify a parent pool in the **addmdisk** command.

CMMVC8526E The command failed because mdisks cannot be removed from a child storage pool.

Explanation

The **mdisk_group_id** or **mdisk_group_name** that was specified in the **rmmdisk** command must be a parent pool.

User response

Specify a parent pool in the **rmmdisk** command.

CMMVC8528E The system does not support encryption.

Explanation

The hardware on this system does not support encryption.

User response

Use a system hardware that supports encryption.

CMMVC8529E The encryption function has not been activated.

Explanation

The system supports encryption but licenses have not been activated.

User response

Activate the encryption function on all I/O groups by installing license keys.

CMMVC8530E A re-key operation is in progress.

Explanation

Command can't be carried out whilst rekey operation is in progress.

User response

Run **chencryption** to commit or cancel current rekey operation.

CMMVC8531E Encryption cannot be disabled while functions are configured to use encryption.

Explanation:

The administrator tried to disable encryption when there are still encryption keys in use and there is presumed to be encrypted data somewhere on the system.

User response

Remove all encrypted objects and try again, or leave encryption enabled while encryption is in use.

CMMVC8532E The encryption function is not enabled.

Explanation

The encryption key cannot be set up until encryption is enabled.

User response

If your system supports encryption, enable encryption and try again. You can find more information by searching for "Enabling encryption".

CMMVC8533E No re-key operation in progress.**Explanation**

No re-key operation to commit or cancel.

User response

Prepare key first and retry commit task.

No action required to cancel.

CMMVC8534E node [X] has insufficient entropy to generate key material.**Explanation**

An internal error occurred during an attempt to generate encryption key material.

User response

Identify the node that is used for key generation, and then retry the command. If the command fails again, complete the following steps, retrying the command after each step until the command runs successfully.

1. Restart the node.
2. If the Trusted Platform Module (TPM) is replaceable, replace the TPM.
3. Replace the node.

CMMVC8535E The system does not have access to current encryption keys.**Explanation**

The system does not have access to the USB flash drives containing current encryption keys.

User response

Locate the USB flash drive containing encryption keys and plug them into the system.

CMMVC8536E The system does not have sufficient USB flash drives attached.**Explanation**

The system does not have sufficient USB flash drives attached. The number needed is displayed.

User response

Insert the specified number of USB flash drives needed into the system and retry.

CMMVC8537E Not enough USB copies made, needs (%1).**Explanation**

The keys have not been written to the minimum number of USB devices.

User response

- Wait for the copies count to reach the minimum required
- Check for USB errors
- Replace flash drive and cancel. Then, retry prepare.

CMMVC8538E System is busy commit in progress.**Explanation**

The system is busy. Commit in progress.

User response

Wait for I/O to complete and commit to complete. Then, use lsencryption to check state.

CMMVC8539E Encryption is not supported on drives IO group**Explanation**

The drive selected is in an I/O group that does not support encryption.

User response

Select a drive in an I/O group that supports encryption.

CMMVC8540E Key not accepted by SAS adapter because of an internal error.**Explanation**

Key not accepted by SAS adapter.

User response

Follow DMP for error shown in lsencryption.

CMMVC8541E The command cannot be initiated because the object is being used by an automatic system configuration task.**Explanation**

This message appears when:

- A failed drive has been reseated or replaced. The system has automatically configured the device.

A drive was automatically managed in the configuration as a replacement for a failed drive. This might have been due to user action of replacing the

failed hardware with a new drive or reseating the old hardware on advice from a DMP.

- An attempt to automatically configure a reseated or replaced drive failed.

A failed drive has been reseated or replaced. The system attempted to automatically configure the reseated or replaced drive for use in the system. This attempt failed.

User response

Wait until the drive auto manage process is complete. An informational or error message appears in the event log.

CMMVC8542E The system update test utility has not been run before updating the system.

Explanation:

Before you can update your system, you need to run the latest version of the test utility to verify that there are no issues with the current system.

User response

Run the system update test utility before you attempt a system update.

CMMVC8544E The command cannot be initiated because the object is being used by an automatic system configuration task.

Explanation:

The chenclosureslot command will no longer work while this new drive auto manage code is running.

User response

Wait until drive automanage finishes before running the chenclosureslot command.

CMMVC8549E The command failed because the source volume is from a child pool.

Explanation

The volumes of a child pool can be migrated only to its parent pool or to a child pool that comes from the same parent.

User response

Choose a target pool that has the same parent as the source volume and retry the command.

CMMVC8550E Cluster ID alias cannot be changed whilst encryption is enabled.

Explanation

Encryption requires that the cluster ID alias does not change while encryption is enabled.

User response

To change the cluster ID alias, disable encryption. Once completed, re-enable encryption.

CMMVC8567E A host of type adminlun is required to be mapped to all IO groups.

Explanation

An attempt was made to change the host type to adminlun, but the host is not in all I/O groups.

User response

Add the host to all I/O groups by using the following command:

```
addhostiogrp -iogrpall host_id
```

You can now change the host type to adminlun.

CMMVC8570E A subsidiary volume may only be mapped to hosts of type adminlun.

Explanation

An attempt was made to map a subsidiary volume to a host that wasn't an adminlun type. Subsidiary LUN mappings are typically created or removed by the IBM Spectrum® Connect application. These mappings apply only to adminlun host types, and so it is unlikely that a storage administrator would encounter this message.

User response

Contact IBM Support.

CMMVC8571E The volume is already mapped as a subsidiary volume.

Explanation

An attempt was made to map a volume as a subsidiary volume, but the volume is already mapped as one. Subsidiary LUN mappings are typically created or removed by the IBM Spectrum Connect application. These mappings apply only to adminlun host types, and so it is unlikely that a storage administrator would encounter this message.

User response

Contact IBM Support.

CMMVC8573E **The action failed because there is one special volume owned by metadata volume in this storage pool.**

Explanation

The **rmmdiskgrp** command failed even though the **-force** parameter was specified. One special volume in the specified storage pool is owned by the metadata volume.

User response

Complete the following steps:

1. Run the **lsmetadatavdisk** command to find the special volume that is owned by the metadata volume.
2. Run the **migratevdisk** command to migrate the special volume from the specified storage pool to a different storage pool.
3. Retry the **rmmdiskgrp** command.

CMMVC8574E **The action failed because some volumes with owner type vvol depend on the metadatavdisk and -ignorevvolsexist was not specified.**

Explanation

An attempt was made to remove a metadata volume that some other volumes depend on.

User response

Complete one of the following actions:

- Remove the vvol type volumes by using the **rmvdisk** command, then retry the **rmmetadatavdisk** command.
- Alternatively, specify the **-ignorevvolsexist** parameter when you retry the command. Using this parameter means that the metadata volume is removed, but the dependent vvol volumes are retained.

CMMVC8575E **The action failed because it depends on NTP server but NTP server is not configured.**

Explanation

During the creation of the metadata volume, an incorrect timestamp was found. The error was caused by the lack of a network time protocol (NTP) server, which is required for the metadata volume.

User response

Create the NTP server by using the following command:

```
chsystem -ntpip
```

After the NTP server is created, retry the **mkmetadatavdisk** command.

CMMVC8587E **The command failed because the volume is fast formatting.**

Explanation

The command cannot be run while the volume is fast formatting.

User response

Wait for the fast formatting process to complete, and then try the command again.

CMMVC8590E **The command failed because the Compare Volume ID or name is invalid.**

Explanation:

The specified Compare Volume ID or name is not valid.

User response:

Specify a valid Compare Volume ID or name and resubmit the command.

CMMVC8591E **The command failed because the Base Volume ID or name is invalid.**

Explanation:

The command failed because the Base Volume ID or name is invalid.

User response:

Specify a Base Volume ID or name and resubmit the command.

CMMVC8592E **The command failed because the Compare Volume does not exist.**

Explanation:

The command failed because the Compare Volume does not exist.

User response:

Specify the ID or name of an existing Compare Volume and resubmit the command.

CMMVC8593E **The command failed because the Base Volume does not exist.**

Explanation:

The command failed because the Base Volume does not exist.

User response:

Specify the ID or name of an existing Base Volume and resubmit the command.

CMMVC8594E **The command failed because the Base and Compare Volumes are the same.**

Explanation:

The command failed because the Base and Compare Volumes are the same.

User response:

Specify Base and Compare Volumes that are not identical and resubmit the command.

CMMVC8595E **The command failed because the startlba of the scan segment is invalid.**

Explanation:

The command failed because the startlba of the scan segment is invalid.

User response:

Specify a valid startlba and resubmit the command.

CMMVC8596E **The command failed because the lbacount of the scan segment is invalid.**

Explanation:

The command failed because the lbacount of the scan segment is invalid.

User response:

Specify a valid lbacount and resubmit the command.

CMMVC8597E **The command failed because the chunk size is invalid.**

Explanation:

The command failed because the specified chunk size is not valid.

User response:

Specify a valid chunk size and resubmit the command.

CMMVC8598E **The command failed because the volume and the base volume are not in the same dependency chain.**

Explanation:

The command failed because the volume and the base volume are not in the same dependency chain.

User response:

Specify base and compare volumes that are in the same dependency chain and resubmit the command.

CMMVC8599E **The command failed because a node is offline.**

Explanation:

A node is offline which caused the command to fail.

User response:

Bring the node back online and resubmit the command.

CMMVC8600E **The command failed because the write cache could not be flushed in time.**

Explanation:

The command failed because the write cache could not be flushed in time.

User response:

Retry the command.

CMMVC8601E **The command failed because the start of the scan segment is not chunk aligned.**

Explanation:

The command failed because the start of the scan segment is not chunk-aligned.

User response:

Specify a startlba that is chunk-aligned and resubmit the command.

CMMVC8620E **The active-active relationship could not be created because the master and auxiliary volumes do not have different well-defined sites.**

Explanation:

The active-active relationship could not be created because the master and auxiliary volumes do not have different well-defined sites.

User response

Contact IBM Support.

CMMVC8621E **The active-active relationship could not be created because the system topology is not HyperSwap.**

Explanation:

The active-active relationship could not be created because the system topology is not HyperSwap.

User response

Contact IBM Support.

CMMVC8622E **The active-active relationship could not be created because the master and auxiliary volumes are not in the same system.**

Explanation:

The active-active relationship could not be created because the master and auxiliary volumes are not in the same system.

User response

Contact IBM Support.

CMMVC8623E I/O group was not specified. I/O group must be specified because topology is HyperSwap.

Explanation:

You cannot set HyperSwap topology without specifying the I/O group.

User response

Specify the I/O group when using HyperSwap technology.

CMMVC8624E Cannot set Hyperswap topology because some nodes do not have a configured site.

Explanation:

Cannot set HyperSwap topology because some nodes do not have a configured site.

User response

Configure the site for each node and then set the topology.

CMMVC8625E Cannot set HyperSwap topology because an I/O group has nodes assigned to different sites.

Explanation:

You cannot set HyperSwap topology when the I/O group has nodes assigned to different sites.

User response

Assign both nodes in the I/O group to the same site or do not attempt to set HyperSwap.

CMMVC8626E Cannot modify site because topology is HyperSwap.

Explanation:

You cannot change the site of a node because the topology is set to HyperSwap.

User response

Change the system topology to standard to change the site of the node.

Warning: Changing the topology disables the disaster recovery (DR) feature.

CMMVC8627E Site was not specified. Site must be specified because topology is Hyperswap.

Explanation:

Site was not specified. Site must be specified because topology is HyperSwap.

User response

Identify the site and resubmit command with -site flag. Alternatively change system topology.

Warning: Changing the topology disables the disaster recovery feature.

CMMVC8628E The host mapping was not created because the volume is not the host accessible volume in an active-active relationship.

Explanation:

A volume cannot be mapped to a host if it is an auxiliary volume in an active-active relationship.

User response

Create the host mapping to the master volume in the relationship.

CMMVC8629E Site specified is not valid. System topology is Hyperswap and the other member of the IO group has been configured to a different site.

Explanation:

Site specified is not valid. System topology is HyperSwap and the other member of the I/O group has been configured to a different site.

User response

Identify the site of the other member of the I/O group. Assign the same site and resubmit. Alternatively, change the system topology.

Warning: Changing the topology will disable the DR feature.

CMMVC8630E Site specified is not valid. System topology is Hyperswap and the node or control enclosure was previously configured with a different site.

Explanation:

Site specified is not valid. System topology is HyperSwap and the node or control enclosure was previously configured with a different site.

User response

Identify the site specified originally for this node or control enclosure and resubmit the command. Or, change the system topology.

Warning: Changing the topology disables the disaster recovery feature.

CMMVC8631E **The change VDisk could not be disassociated because it is configured in an active-active relationship.**

Explanation:

A change volume cannot be disassociated from an active-active relationship.

User response

Contact IBM Support.

CMMVC8632E **The copy type of an active-active relationship or group cannot be changed.**

Explanation:

The copy type of an active-active relationship or group cannot be changed.

User response

Contact IBM Support.

CMMVC8633E **The relationship could not be added to the consistency group because it does not have an up-to-date copy in the same site as a set of up-to-date copies in the group.**

Explanation:

When adding an active-active relationship to a consistency group, the relationship must have an up-to-date copy in the same site as a set of up-to-date copies of each relationship in the consistency group.

User response

Before attempting to add the relationship to the consistency group, verify that the copy in the candidate relationship is as up-to-date as the set of up-to-date copies of any existing relationship in the consistency group.

CMMVC8634E **The host mapping was not created because the host does not have a site defined and the volume is in an active-active relationship.**

Explanation:

A volume in an active-active relationship can only be mapped to a host if the host has a site defined.

User response

Set the site for the host using the management GUI or the lshost and chhost CLI commands.

CMMVC8635E **Cannot un-set the host site as the host is mapped to a volume in an active-active relationship.**

Explanation:

A host mapped to a volume in an active-active relationship must have a site defined.

User response

Keep the site defined or remove the host mapping if un-setting the host site is required.

CMMVC8636E **The active-active relationship was not created because one or more hosts mapped to the master volume do not have a site defined.**

Explanation:

A host mapped to a volume in an active-active relationship must have a site defined.

User response

Set the site of all hosts that are mapped to the master volume before resubmitting the command.

CMMVC8637E **The active-active relationship could not be created because there are one or more host mappings to the auxiliary volume.**

Explanation:

The active-active relationship could not be created because there are one or more host mappings to the auxiliary volume.

User response

Contact IBM Support.

CMMVC8638E **An active-active relationship or group may not be manually started unless it has a state of idling and access has previously been enabled to an out-of-sync consistent copy.**

Explanation:

An active-active relationship or group may not be manually started unless it has a state of idling and access has previously been enabled to an out-of-sync consistent copy.

User response

Contact IBM Support.

CMMVC8639E **An active-active relationship or group may not be manually stopped unless it has a state of consistent_copying and access is required to the out-of-sync consistent copy.**

Explanation:

An active-active relationship or group may not be manually stopped unless it has a state of `consistent_copying` and access is required to the out-of-sync consistent copy.

User response

Contact IBM Support.

CMMVC8640E	Active-active relationships and groups alter their direction automatically and cannot have their direction switched manually.
-------------------	--

Explanation:

Active-active relationships and groups alter their direction automatically and cannot have their direction switched manually.

User response

Contact IBM Support.

CMMVC8642E	The command failed because the copy specified is not synchronized. The copy must be synchronized to create an active-active relationship.
-------------------	--

Explanation:

Only volumes where both copies are synchronized can be split when creating an active-active relationship. The command failed because the specified copy is not synchronized.

User response

Contact IBM Support.

CMMVC8643E	The active-active relationship could not be created because the existing and new volumes do not have different well-defined sites.
-------------------	---

Explanation:

The active-active relationship could not be created because the existing and new volumes do not have different well-defined sites.

User response

Contact IBM Support.

CMMVC8644E	The command failed because the auxiliary volume does not contain an up-to-date copy or have host access enabled.
-------------------	---

Explanation:

The master volume in an active-active relationship (keeping host access to the auxiliary volume) can only be removed when the auxiliary volume is already

processing host I/O. Either it is an up-to-date copy of an active-active relationship or the copy has host access enabled with the "stoprrrelationship -access" command.

User response

Contact IBM Support.

CMMVC8646E	The active-active relationship could not be created, either because the master or auxiliary volume is the target of a FlashCopy mapping or because the master or auxiliary volume is the source of a FlashCopy mapping with a target volume in a different site.
-------------------	---

Explanation

The active-active relationship could not be created because:

- The master or auxiliary volume is the target of a FlashCopy mapping.
- The master auxiliary volume is the source of a FlashCopy mapping with a target volume in a different site.

User response

Contact Support.

CMMVC8649E	Cannot change topology because active-active relationships are defined, and only supported in Hyperswap topology.
-------------------	--

Explanation:

It is not possible to change the topology because active-active relationships are defined and only supported in a HyperSwap topology.

User response

Remove all active-active relationships before changing the topology.

CMMVC8650E	System topology is Hyperswap or stretched, and the site of the MDisk being added does not match that of the storage pool.
-------------------	--

Explanation:

The system topology is either HyperSwap or stretched and the site of the MDisk you are adding does not match the storage pool.

User response

Do one of the following:

- Add the MDisk to an empty storage pool or to one already containing MDisk of a matching site.
- Remove and re-add the controller of the MDisk in the desired site.

Then, retry the command.

CMMVC8652E The command failed because the volume is owned and has restricted use.

Explanation

You cannot specify this command for this volume because the volume is owned and has restricted use.

User response

Choose a volume that is not owned with restricted use.

CMMVC8653E The command failed as an MDisk group is owned and has restricted use.

Explanation:

An MDisk group specified in the command is owned and either the action is not allowed for this type of owner or the user requires a specific role.

User response:

Check if the MDisk group is owned and then make sure the command is permitted for this type of owner or the required role is being used.

CMMVC8654E The storage pool specified is not valid. The volume is a participant in an active-active relationship, and the storage pool for the new copy is in a different site to the volume's current site.

Explanation

Participants in an active-active relationship must be located in the same site.

User response

Move the volume to a storage pool in the same site, or move the other copy in the active-active relationship to the target storage pool.

CMMVC8655E The volume being moved is a participant in an active-active relationship, and the target storage pool is in a different site to the volume's current site.

Explanation

The members of an active-active relationship must be located on the same site.

User response

Move the volume to a storage pool in the same site, or move the other copy in the active-active relationship to the target storage pool.

CMMVC8657E The command failed as the specified storage pool is offline.

Explanation

The storage pool that was specified in the command is offline.

User response

1. Determine why the storage pool is offline. You can use the **lseventlog** command to determine the event that caused the problem.
2. Correct the problem that is shown in the output of the **lseventlog** command.
3. Retry the **mkmetadatavdisk** command.

CMMVC8658E The create failed because there are no iogroups supporting compression.

Explanation

An attempt was made to create a compressed volume where the **-iogrp** parameter was not specified and none of the candidate I/O groups for the command support compression.

User response

Retry the command and use the **-iogrp** parameter to specify an I/O group that supports compression. Alternatively, retry the command without the **-compressed** parameter.

CMMVC8659E The Create FlashCopy mapping task cannot be initiated because the target volume is in an active-active relationship.

Explanation

An attempt was made to create a FlashCopy mapping with a HyperSwap volume as a target. HyperSwap volumes cannot be used as targets for FlashCopy mappings. This rule applies to both the master and auxiliary volumes of the active-active relationship.

User response

If you must use FlashCopy to create a point-in-time copy of a volume onto a HyperSwap volume, that target HyperSwap volume must be reconfigured as a regular volume until the FlashCopy process completes.

Use the management GUI or the **rmvolumecopy** command to delete one copy of the target HyperSwap volume before you create the FlashCopy mapping.

CMMVC8660E **The Create FlashCopy mapping task cannot be initiated because the source volume is in an active-active relationship and the target volume and map are not in the same site as the source volume.**

Explanation

HyperSwap volumes contain a copy on each site, and copying data from one site to the other introduces significant unnecessary data movement. When you create a FlashCopy mapping to copy data on a HyperSwap volume, the source volume of the FlashCopy mapping must be the HyperSwap volume copy that is on the same site as the target volume.

User response

Retry the command, specifying as a source volume the HyperSwap volume copy that is on the same site as the target volume.

CMMVC8661E **The command has failed because the specified volume is a target of a FlashCopy mapping with a source volume in an active-active relationship and the new I/O group is in a different site to the source volume.**

Explanation

An attempt was made to move the preferred node of a volume to an I/O group on a different site when the volume is a target of a FlashCopy mapping with a source volume in an active-active relationship. For FlashCopy mappings that copy data from a HyperSwap volume, the source volume of the FlashCopy mapping must be on the same site as the target volume.

User response

Retry the command and move the volume to another I/O group on the same site. Alternatively, to move the volume to an I/O group on the other site, remove the FlashCopy mapping or convert the HyperSwap source volume to a regular volume by using the management GUI or the **rmvolumecopy** command first.

CMMVC8662E **The command has failed because the specified volume is a target of a FlashCopy mapping with a source volume in an active-active relationship and the target storage**

pool is in a different site to the source volume.

Explanation

HyperSwap volumes contain a copy on each site, and copying data from one site to the other introduces significant unnecessary data movement. For a FlashCopy mapping that copies data from a HyperSwap volume, the source volume of the FlashCopy mapping must be on the same site as the target volume.

User response

Retry the command and move the volume to a storage pool on the same site. Alternatively, to move the volume to a storage pool on the other site, convert the HyperSwap source volume to a regular volume by using the management GUI or the **rmvolumecopy** command first.

CMMVC8663E **The command has failed because the specified volume is a target of a FlashCopy mapping with a source volume in an active-active relationship and the storage pool for the new copy is in a different site to the source volume.**

Explanation

HyperSwap volumes contain a copy on each site, and copying data from one site to the other introduces significant unnecessary data movement. For a FlashCopy mapping that copies data from a HyperSwap volume, the source volume of the FlashCopy mapping must be entirely on the same site as the target volume. This command would spread the volume across both sites.

User response

Complete one of the following actions:

- Delete the FlashCopy mapping and retry the command.
- Move the FlashCopy target volume to the same site as the source volume:
 1. Use the **movevdisk** command to change the I/O group for the target volume to one on the same site as the source volume.
 2. Use the **migratevdisk** command to change the storage pool for the target volume to a storage pool on the same site as the source volume.

Then retry the command.

CMMVC8664E **The change volume could not be associated because it does not have the same well-defined site as the associated volume in the relationship.**

Explanation

Change volumes support HyperSwap volumes by capturing consistent data during synchronization. This process allows access to the consistent data if the remote site is lost. The change volume must be on the correct site for the volume in the active-active relationship it is being associated with.

User response

Configure the change volume in an I/O group and storage pool on the same site as the volume in the active-active relationship you are associating it with.

CMMVC8665E **The FlashCopy mapping was not started because the source volume is in an active-active relationship and does not contain an up-to-date copy or have host access enabled.**

Explanation

HyperSwap volumes contain a copy on each site, and copying data from one site to the other introduces significant unnecessary data movement. For a FlashCopy mapping that copies data from a HyperSwap volume, the HyperSwap volume must have an up-to-date copy on the same site as the target volume of the FlashCopy mapping.

User response

Allow the HyperSwap volume to synchronize fully before you start the FlashCopy mapping. Alternatively, create and use a FlashCopy mapping on the same site as the up-to-date copy of the HyperSwap volume.

CMMVC8666E **The FlashCopy consistency group was not started because one or more of the source volumes are in an active-active relationship and do not contain an up-to-date copy or have host access enabled.**

Explanation

HyperSwap volumes contain a copy on each site, and copying data from one site to the other introduces significant unnecessary data movement. For a FlashCopy consistency group that has one or more maps that copy data from a HyperSwap volume, the HyperSwap volume must have an up-to-date copy on

the same site as the target volume of the FlashCopy mapping.

User response

Allow the HyperSwap volume to synchronize fully before you start the FlashCopy mapping. Alternatively, create and use a FlashCopy mapping on the same site as the up-to-date copy of the HyperSwap volume.

CMMVC8667E **The command failed because a specified host port has more than four logins on a node.**

Explanation

At least one host port (WWPN or IQN) has more than four logins to the same node. The network or SAN might not be zoned correctly. The system supports up to four logins per node from the same host port.

User response

Complete the following steps. If at any point you need more assistance, contact your service support representative.

1. Create a list of the problem hosts, WWPNs, and nodes.
 - a. Run the **svcinfo lsfabric -host** command and parse the output into a human-readable format.
 - b. Sort by WWPN, then by node.
 - c. For any WWPN and node combination that shows more than four logins, complete the following steps:
 - 1) Get the host port mask from the mask field of the **lshost** detailed view.
 - 2) Ignore any row where the local_port field does not match the appropriate bit in the host port mask.
 - 3) Make a note of any hosts that still show more than four logins after the host port mask is applied.
2. Fix the issue either by changing the zoning or by changing the host port mask.

CMMVC8668E **The host mapping was not created because the SCSI logical unit number (LUN) ID is not valid for this particular host type.**

Explanation

An attempt was made to create a mapping between a volume and an adminlun host, but the SCSI LUN ID is not within the range for adminlun hosts. The highest

SCSI LUN ID that is permitted for an adminlun host is 512.

User response

Retry the command with a valid SCSI LUN ID.

CMMVC8670E Cannot modify host type since it has subsidiary mappings.

Explanation

An attempt was made to change the host type from adminlun to another host type, but the adminlun host has subsidiary mappings. Only adminlun hosts can have subsidiary mappings.

User response

Contact a VMware administrator to ensure that all Virtual Volume datastores are unmounted from the specified host because this operation removes all remaining subsidiary mappings. After the process is complete, retry the command.

CMMVC8671E An existing volume is mapped with a SCSI ID which exceeds the maximum for this host type.

Explanation

An attempt was made to change the host type to adminlun, but an existing volume is mapped with a SCSI ID that exceeds the maximum SCSI ID for an adminlun host. The SCSI ID for an adminlun host type must be below 512.

User response

Ensure that all volumes that are mapped to the host have a SCSI ID below 512, and then change the host type to adminlun. If not all volumes that are mapped to the host have a SCSI ID below 512, then remove mappings with a SCSI ID of 512 or above. If a mapping is still needed, re-create the mapping with a SCSI ID that is below 512.

CMMVC8672E The command failed because the access IO group set of a subsidiary volume may not be modified.

Explanation

An attempt was made to modify the access I/O group set for a subsidiary volume, which is required to be available through all I/O groups.

User response

You cannot modify access of a subsidiary volume. Retry the command for a different volume.

CMMVC8673E The volume is already mapped as a SCSI LUN which must first be unmapped/removed in order to create a subsidiary volume mapping.

Explanation

An attempt was made to create a subsidiary volume mapping, but the volume is already mapped as a SCSI LUN. Subsidiary LUN mappings are typically created or removed by the IBM Spectrum Connect application. These mappings apply only to adminlun host types, and so it is unlikely that a storage administrator would encounter this message.

User response

Contact IBM Support.

CMMVC8674E The volume is not mapped as a subsidiary LUN.

Explanation

An attempt was made to remove a subsidiary mapping between an adminlun host and a volume, but the volume was not a subsidiary volume.

User response

Specify a valid volume ID and retry the command.

CMMVC8676E The command failed because the volume is not a master volume in an active-active relationship.

Explanation:

This command retains access to a HyperSwap volume when deleting the master volume of its active-active relationship. It is not necessary or permitted when deleting the auxiliary volume of its active-active relationship, or any non-HyperSwap volume.

User response

Retry the command on the correct object type.

CMMVC8677E Retaining access to the auxiliary VDisk failed because either the master or the auxiliary VDisk is in mirrored mode.

Explanation:

The master volume in an active-active relationship can only be removed, keeping host access to the auxiliary volume, when both the master and auxiliary volumes are in non-mirrored volume.

User response

Remove additional mirrors of the master and auxiliary volumes of the active-active relationship so each has only one mirror, then retry the command.

CMMVC8696E **The command failed because the volume or a volume copy is in the deleting state.**

Explanation

An action was requested on a volume or a volume copy that was in the process of being deleted.

User response

Make sure that you specified the correct volume. If so, the requested action is not supported on volumes or volume copies that are deleting.

CMMVC8697E **The command failed because the source or target volume is in the deleting state.**

Explanation

An attempt was made to delete a volume that was already in the process of being deleted.

User response

Complete the following actions:

1. Make sure that you specified the correct volume.
2. If so, wait until the previous **rmvdisk** command completes.
3. If you believe that the previous command failed, and you are sure that you want to proceed, you can retry the command with the **-force** parameter. Using the **-force** parameter bypasses all built-in safety checks.

CMMVC8698E **The command failed because the volume has host mappings, use -removehostmappings.**

Explanation

An attempt was made to delete a volume that has host mappings.

User response

Make sure that you specified the correct volume. If so, and you want to delete the host mappings along with the volume, retry the command and include the **-removehostmappings** parameter.

CMMVC8699E **The command failed because the volume is image mode and has**

FlashCopy maps, either remove the FlashCopy maps first or use -force.

Explanation

An attempt was made to delete an image mode volume that has FlashCopy maps.

User response

Complete the following steps:

1. Make sure that you specified the correct volume.
2. If so, remove the FlashCopy maps by using the **rmfcmaps** command and retry the **rmvdisk** command.
3. Alternatively, you can retry the **rmvdisk** command with the **-force** parameter. Using the **-force** parameter bypasses all built-in safety checks.

CMMVC8706E **The command failed because the primary copy's autodelete flag is on, meaning type conversion is in progress.**

Explanation

Changing the primary copy (using the **chvdisk -primary** command) is disabled when the primary copy's autodelete flag is on.

User response

Change the primary copy when the primary copy's **autodelete** is **no**.

Either wait for the type conversion to finish or cancel the process, if required, by using the **rmvdiskcopy** command.

CMMVC8707E **The command failed because the caching IO groups for the volume are not in two independent sites.**

Explanation

When you create HyperSwap volumes, the caching I/O groups must be located in both site 1 and site 2.

User response

Ensure that you have caching I/O groups in both site 1 and site 2, then retry the command.

CMMVC8708E **The command failed because the system does not have a hyperswap topology.**

Explanation

An attempt was made to create a HyperSwap volume on a system that does not have a HyperSwap topology. The **mkvolume** command attempts to create a HyperSwap volume in either of the following circumstances:

- Two I/O groups are specified in the command
- Two storage pools are specified within two independent sites that have a HyperSwap topology. In this case the **iogrp** parameter can be omitted and the system will auto-select an I/O group.

User response

Complete one of the following actions:

- If you entered the command incorrectly, correct the command and retry.
- Enter the **mkvolume** command with a single **-iogrp** parameter to create a basic volume.
- Configure the system to use a HyperSwap topology and retry the command.

CMMVC8709E The command failed because the caching IO groups are not in the same sites as the storage pools.

Explanation

When you create volumes under a HyperSwap topology, the caching I/O groups must be in the same sites as the storage pools.

User response

Ensure that the caching I/O groups are in the same sites as the storage pools, then retry the command.

CMMVC8710E The command failed because there were not enough extents in storage pool *storage_pool*.

Explanation

Volumes are created from the extents that are available in a storage pool. An attempt was made to create a volume when not enough extents were available.

User response

If you specified the correct storage pool, complete one of the following tasks:

- Reduce the size of the volume you are creating.
- Add more objects to the pool.

Then, retry the command.

CMMVC8711E The command failed because too many IO groups were specified.

Explanation

The maximum number of I/O groups is 2.

User response

Retry the command, specifying 2 or fewer I/O groups.

CMMVC8712E The command failed because too many storage pools were specified.

Explanation

An attempt was made to create a volume or volume copy that referenced more than two storage pools. The following limits are enforced:

- For the **mkvdisk** command: two mirrored copies.
- For the **mkvolume** command with standard or stretched topology: two mirrored copies.
- For the **mkvolume** command with HyperSwap topology: two volume copies.

User response

Retry the command with no more than two storage pools specified.

CMMVC8713E The command failed because the storage pool must be in site 1 or 2.

Explanation

When you create a volume under a stretched or HyperSwap topology, the storage pool must be located in either site 1 or site 2.

User response

Ensure that your storage pool is in either site 1 or site 2, then retry the command.

CMMVC8714E The command failed because the number of IO groups specified was different to the number of storage pools specified.

Explanation

When you create HyperSwap volumes, the number of I/O groups that you specify must equal the number of storage pools that you specify.

User response

Retry the command, specifying an equal number of I/O groups and storage pools.

CMMVC8715E **The command failed because the storage pools for the volume are not in two independent sites. Volumes can only be created using storage in site 1 and site 2.**

Explanation

When you create stretched or HyperSwap volumes with two storage pools, the pools must be located in independent sites, that is, in both site 1 and site 2.

User response

Ensure that you have storage pools in both site 1 and site 2, then retry the command.

CMMVC8716E **The create failed because there are no iogroups in site *site_number*.**

Explanation

When no I/O group is specified, the system automatically selects an I/O group for the volume in the same site as the MDisk or storage pool that was specified in the command. However, an attempt was made to create a volume in a site where no non-empty I/O groups existed.

User response

Add at least one non-empty I/O group to the site and then retry the command.

CMMVC8717E **The create failed because there are no iogroups supporting compression in site *site_number*.**

Explanation

When no I/O group is specified, the system selects the I/O group for the volume automatically. No non-empty I/O groups that support compression were found in the site of the specified MDisk or storage pool.

User response

Complete one of the following tasks:

- Specify an existing I/O group that supports compression.
- Specify an MDisk or storage pool in a site with a non-empty I/O group that supports compression.
- Reconfigure your system so that the specified MDisk or storage pool is in a site that contains a non-empty I/O group that supports compression.

CMMVC8718E **The command failed because the managed disk must be in site 1 or 2.**

Explanation

Under a stretched or a HyperSwap topology, the managed disk must be in site 1 or site 2.

User response

Ensure that the managed disk is in site 1 or site 2 and retry the command.

CMMVC8719E **The command failed because one or more service IP addresses aren't set.**

Explanation:

The quorum application requires a connection to all nodes in the cluster by using the service IP addresses.

User response

1. Determine which IP version needs to be used by the quorum application to connect to the cluster: IPv4 (default) or IPv6. To change the default IP version, use the **mkquorumapp -ip_v6** command.
2. The service IPs of the IP version you are not using might be blank and are not used.
3. Check that the IPv4 or IPv6 service IPs of all nodes in the cluster are set.
4. Set any blank IPv4 or IPv6 service IPs. To set a service IP, use the **satask chserviceip** command.
5. Reissue the command.

CMMVC8720E **The command failed because the IP address provided is already configured as a DNS server.**

Explanation

Each configured DNS server must have a different IP address.

User response

Retry the command with a different IP address.

CMMVC8721E **The command failed because the IP address provided is already in use by this system.**

Explanation

The IP address that is specified in the command is an IP address on the current system and the system does not provide a DNS service.

User response

Provide the correct IP address of a DNS server.

CMMVC8722E The command has failed because DNS server cannot be removed while DNS clients are configured.

Explanation

The last configured DNS server can be deleted only if no DNS clients are configured.

User response

Stop all DNS clients for the specified server and then retry the command. Because different kinds of DNS clients can trigger this message, specific instructions for stopping the clients cannot be provided here. Refer to the product documentation or contact your service support representative.

CMMVC8723E The command failed because the system does not support the cloud gateway function.

Explanation

An attempt was made to enable the cloud gateway function when at least one node in the system does not support the function.

User response

Check the hardware compatibility matrix in the documentation. Remove the nodes that do not support the function from the system and try again.

CMMVC8724E The command failed because the candidate does not support cloud snapshots and there is a configured cloud account.

Explanation

An attempt was made to add a node or enclosure that does not support cloud snapshots to a system on which the cloud snapshot function is enabled.

User response

Add a different node, or disable cloud snapshots by using the **rmcloudaccount** command and try again.

CMMVC8725E The command failed because DNS servers are not configured.

Explanation

An attempt was made to configure a cloud account, but the system does not have any configured DNS servers.

User response

Configure at least one DNS server by using the **mkdnserver** command, and then retry the **mkcloudaccountawss3** command.

CMMVC8726E The command failed because the encryption capability is not currently available on this system.

Explanation

An attempt was made to configure an encrypted cloud account, but the encryption capability is not currently available on this cluster.

User response

Enable encryption on the system by using the **chencryption** command, then retry the **mkcloudaccount** command.

CMMVC8727E The command failed because the cloud gateway service is offline.

Explanation

An attempt was made to test or modify the properties of a cloud account. The system cloud gateway service has reset too often and is being held offline. Cloud accounts cannot be manipulated when they are in this state.

User response

Check the log for an alert event that is related to this error. Mark the event as fixed, and the system will try to bring the account online. If the attempt fails, a new error message is displayed. Refer to the documentation for the displayed error code for further instructions, then resubmit the command.

CMMVC8728E The command failed because the cloud account is with a different provider.

Explanation

An attempt was made to modify an existing cloud account, but the wrong command was used. For example, if a cloud account is created that uses AWS S3 as the cloud provider, only the **chcloudaccountawss3** command can be used to modify it.

User response

Use the command that is appropriate to the account type to modify an account.

CMMVC8729E The command failed because the maximum number of systems are already using the cloud account.

Explanation

An attempt was made to configure a cloud account with credentials that identify cloud storage that is already being used by the maximum number of systems.

User response

Specify different cloud storage or stop some systems from using the specified cloud storage.

CMMVC8730E The command failed because of a problem accessing metadata objects in the cloud storage.

Explanation

An attempt was made to access cloud storage that was written by a different system, or by the current system at a different time. The current system cannot correctly read the metadata that was written to the cloud storage by the originating system.

User response

Verify with your cloud service provider that the cloud storage is working correctly. If you are trying to access cloud storage that was written by a different system, verify that the system is working correctly. Retry the command.

CMMVC8731E The command failed because the metadata objects were created by a more recent version of code that is incompatible with this system.

Explanation

An attempt was made to access cloud storage that was written by a different system, or by the current system at a different time. The metadata that was created by the other system is not compatible because the other system is running a more recent level of code than the current system.

User response

Update the code level of the current system to match that of the other system, then retry the command.

CMMVC8732E The command failed because the new credentials identify different cloud storage.

Explanation

An attempt was made to change the login details of a cloud account. The new details work, but the cloud storage resources that are accessible by using the new details are different from the storage resources that the system is using.

User response

If you want to use different cloud storage resources, set up a new cloud account object. If you do not want to use different resources, check the details that you are trying to change and try the command again.

CMMVC8733E The command failed because there is at least one cloud account configured.

Explanation

Ordinarily, this error is seen only by service support representatives. An attempt was made to modify the cluster ID alias. At least one cloud account is configured that is using the current cluster ID alias to identify data in the cloud. The cluster ID alias cannot be changed in this situation because data exists in cloud storage that refers to it.

User response

If you specified the correct cluster and must change the cluster ID alias, you must first delete the associated cloud account by using the **rmcloudaccount** command. You can then retry the **chsystem** command.

CMMVC8734E The command failed because the system cannot resolve the hostname of the cloud provider.

Explanation

The system cannot resolve the host name that is associated with the cloud provider by using the configured DNS servers for the system. For some cloud providers, the user entered this host name. For others, such as Amazon S3, the system determines the host name.

User response

If an endpoint URL that contains a host name is associated with the cloud account, verify that the host name is correct. Verify that the system DNS servers are configured correctly and are working correctly.

After you correct any problems that you find, retry the command.

CMMVC8735E The command failed because the system cannot contact the cloud provider server on the management network.

Explanation

The system cannot contact the cloud provider over the management Ethernet network.

User response

If an endpoint URL that contains an IP address is associated with the cloud account, verify that the IP address is correct. Determine why the system management IP address cannot contact the cloud provider; a firewall might be in the way, or the cloud account provider might be experiencing problems. After you correct any problems that you find, retry the command.

CMMVC8736E The command failed because the system cannot establish a connection with the cloud provider software.

Explanation

The system cannot communicate with the cloud provider server software. The cloud provider address on the system might be configured incorrectly or the cloud provider might be having a problem.

User response

If an endpoint URL is associated with the cloud account, verify that the URL is correct. Check that the cloud provider is functioning correctly and is compatible with the system. After you correct any problems that you find, retry the command.

CMMVC8737E The command failed because the system does not have a CA SSL certificate for the cloud provider server.

Explanation

An attempt was made to configure a cloud account that uses SSL. The cloud provider server presented a certificate, but the system cannot verify its authenticity because the system does not have a corresponding certificate authority (CA) certificate.

User response

Contact the cloud provider and obtain the appropriate CA certificate. Or, if SSL is not a requirement, see whether the cloud provider will support a connection where SSL is disabled.

CMMVC8738E The command failed because the SSL certificate has expired.

Explanation

An attempt was made to configure a cloud account that uses SSL, and an SSL certificate was provided, but the current system time is not within the validity period for the certificate.

User response

Verify that the system time is correct. If so, contact the cloud provider to obtain a valid SSL certificate.

CMMVC8739E The command failed because the SSL certificate is not valid.

Explanation

An attempt was made to configure a cloud account that uses SSL. The SSL certificate that was supplied does not work because it is not valid or because it uses features that the system does not support.

User response

Verify that the certificate that you supplied is a valid X509 SSL CA certificate in PEM format. If not, replace the certificate. Verify that the system security setting is compatible with the cloud provider. After you correct any problems that you find, retry the command.

CMMVC8740E The command failed because the account credentials were rejected by the cloud provider.

Explanation

The cloud provider did not accept the login credentials that were configured on the local system.

User response

Verify that the time is set correctly on the system. Verify that the credentials that were entered on the system match valid credentials on the cloud provider. After you correct any problems that you find, retry the command.

CMMVC8741E The command failed because the account credentials do not give

permission to access the cloud storage containers.

Explanation

The cloud provider accepted the login credentials that were configured on the local system, but they do not give the system enough permissions to use cloud storage.

User response

Verify that the container prefix that is associated with the cloud account is available and not in use by other cloud clients. Either change the credentials so that they specify a user that has more permissions, or access the cloud provider and give the current user the necessary permissions, as described in the system documentation.

CMMVC8742E The command failed because of an error communicating with the cloud provider.

Explanation

The system encountered an unexpected error when it attempted to communicate with the cloud provider.

User response

Verify that the cloud provider is working normally. Check the system event log for alerts. If you cannot determine the source of the problem, contact your service support representative.

CMMVC8743E The command failed because the region specified is not valid.

Explanation

An attempt was made to configure an Amazon Web Services (AWS) S3 cloud account, but the specified AWS region was not recognized.

User response

Retry the command with a valid region. To find a valid region, check the list of regions that are supported by AWS S3 on the AWS website:

<https://aws.amazon.com/about-aws/global-infrastructure/regional-product-services/>

CMMVC8744E The command failed because the bucket prefix is already in use.

Explanation

An attempt was made to configure a cloud account that uses Amazon Web Services, but the bucket prefix was already in use.

User response

Check the Amazon Web Services documentation on bucket naming. Choose another bucket prefix and retry the command.

CMMVC8745E The command failed because the system is in Gen1 compatibility mode.

Explanation

You cannot configure a cloud account when the system is in Storwize V7000 Gen1 compatibility mode.

User response

Complete the following steps:

1. Ensure that no Storwize V7000 Gen1 canisters are attached to the system.
2. Disable Gen1 compatibility mode by entering the **chsystem -gen1compatibilitymode no** command.
3. Retry the **mkcloudaccountawss3** command.

CMMVC8746E The command failed because an account with an SSL certificate must have an https endpoint.

Explanation

If you provide an SSL certificate when you configure a cloud account, you must provide an endpoint URL that requires SSL. If you provide an endpoint that does not use https, you must not provide an SSL certificate.

User response

Retry the command, either with an https endpoint URL or without the SSL certificate.

CMMVC8748E The command failed because the cloud data is encrypted with the wrong key.

Explanation

The master key associated with the cloud data does not match the master key that was used when the system was created. Cloud snapshot services remain unavailable until this problem is fixed.

User response

Locate the correct master key and make it available to the cluster, either on a USB drive or on a network key server. Then, retry the command.

CMMVC8749E **The command failed because the specified volume group is not empty.**

Explanation

An attempt was made to delete a volume group that contains volumes. Volume groups cannot be deleted while they contain volumes.

User response

Remove the volumes from the group by using the **chvdisk -novolumegroup** command and try again.

CMMVC8750E **The command failed because the specified volume group already contains the maximum number of volumes.**

Explanation

The volume cannot be added to the specified volume group after its maximum volume member limit is reached.

User response

Try one of the following solutions:

- Use the specified volume as a stand-alone volume.
- Remove an existing volume from the group by using the **chvdisk -novolumegroup** command, then try again to add the new volume.
- Retry the command and specify a different volume group.

CMMVC8751E **A new cloud snapshot could not be created because the volume group does not contain any volumes.**

Explanation

An attempt was made to back up an empty volume group.

User response

Add at least one volume to the group and try again. Alternatively, specify a different volume group.

CMMVC8752E **A cloud snapshot could not be created because the cloud FlashCopy function is not enabled for all the volume group members.**

Explanation

An attempt was made to back up a volume group where at least one volume in the group does not have the cloud snapshot function enabled. A new cloud snapshot can be created only when the cloud backup function is enabled for all the volume group members.

User response

Enable the cloud snapshot function for all the volumes in the group and try again. Use the following command to enable cloud snapshots for a volume:

```
chvdisk -backup cloud -enable -account  
account volume
```

CMMVC8753E **A new cloud snapshot could not be created because a cloud snapshot operation is already in progress.**

Explanation

A new cloud snapshot can be started only when the volume **backup_status** is **ready**.

User response

Wait for the existing cloud snapshot operation to complete, or cancel the cloud snapshot. Use the management GUI or the **lsvolumebackupprogress** command to monitor the progress of the cloud snapshot, or the **rmvolumebackupgeneration** command to cancel the cloud snapshot.

CMMVC8754E **A cloud snapshot could not be created because a restore operation is already in progress.**

Explanation

A new cloud snapshot cannot be started while the volume is being restored.

User response

Make sure that you specified the correct volume. If so, wait for the existing restore operation to complete, or cancel the restore. Use the management GUI or the **lsvolumerestoreprogress** command to monitor the progress of the restore, or the **restorevolume** command to cancel the restore.

CMMVC8755E **The command failed because the system does not support the volume group function.**

Explanation

An attempt was made to enable the volume group function, but at least one node in the system does not support the function.

User response

Check the hardware compatibility table in the documentation. Remove the nodes that do not support the function from the system and try again.

CMMVC8756E A new cloud snapshot could not be created because the volume is part of a volume group.

Explanation

A new cloud snapshot can be created only if the volume is not part of a volume group.

User response

Remove the volume from the group or use the **backupvolumegroup** command to create a cloud snapshot of the entire group.

CMMVC8757E Cannot change facility because CADF reporting is set.

Explanation

An attempt was made to change the facility code for the syslog server. The facility code is automatically set to 8 when Cloud Auditing Data Federation (CADF) reporting is enabled.

User response

To change the facility code, you must first disable CADF reporting by using the **chsyslogserver - cadf off** command.

CMMVC8758E Cloud snapshots cannot be enabled because there are insufficient free volume copy IDs in the system.

Explanation

The cloud snapshot function requires IDs to create two internal volumes in the same caching I/O group as the volume.

User response

Remove unwanted volumes or volume copies from the system by using the **rmvolume** or **rmvolume copy** command, and then retry the command.

CMMVC8759E Cloud snapshots cannot be enabled because there are insufficient free volume copy IDs in the caching I/O group of the volume.

Explanation

The cloud snapshot function requires IDs to create two internal volumes in the same caching I/O group as the volume.

User response

Complete one of the following actions:

- Remove unwanted volumes from the caching I/O group.
- Move the volume to a different I/O group.

Then, retry the command.

CMMVC8760E Cloud snapshots cannot be enabled because there is insufficient free capacity in the storage pool.

Explanation

The cloud snapshot function requires added storage capacity in the storage pool of the volume.

User response

Complete one of the following actions:

- Add capacity to the storage pool by using the **addmdisk** command, or use the **mkarray** command if using internal drives.
- Remove unwanted volumes from the storage pool by using the **rmvdisk** command.
- Move the volume to a different storage pool by using the **migratevdisk** command.

CMMVC8761E Cloud snapshots cannot be enabled because the maximum number of FlashCopy mappings in the system has been reached.

Explanation

The cloud snapshot function configures two internal FlashCopy mappings per volume.

User response

Remove unwanted FlashCopy mappings from the system and retry the command.

CMMVC8762E Cloud snapshots cannot be enabled because there is

insufficient memory available for FlashCopy.

Explanation

The restore operation requires an internal FlashCopy mapping to be created, but the system limit was reached.

User response

Remove unwanted FlashCopy mappings from the system by using the **rmfcmap** command and retry the command.

CMMVC8763E Cloud snapshots cannot be enabled because this volume is part of a FlashCopy mapping.

Explanation

The cloud snapshot function cannot be used with volumes that are the source or target of a FlashCopy mapping.

User response

Make sure that you specified the correct volume. If so, remove all FlashCopy mappings that include this volume and retry the command.

CMMVC8764E Cloud snapshots cannot be enabled because this volume is part of a Metro Mirror or Global Mirror relationship.

Explanation

The cloud snapshot function cannot be used with volumes that are in a remote copy relationship.

User response

Make sure that you specified the correct volume. If so, remove the remote copy relationship that includes this volume and retry the command.

CMMVC8765E Cloud snapshots cannot be enabled because this is a HyperSwap volume.

Explanation

The cloud snapshot function cannot be used with HyperSwap volumes.

User response

Make sure that you specified the correct volume. If so, convert the volume to a basic volume by removing a copy at one site, then retry the command.

CMMVC8766E Cloud snapshots cannot be enabled because the volume is mirrored between two different pools.

Explanation

The cloud snapshot function cannot be used with volumes that have copies in different pools.

User response

Make sure that you specified the correct volume. If so, convert the volume to a basic volume by removing a copy, then retry the command.

CMMVC8767E Cloud snapshots cannot be enabled because the volume is being migrated between pools.

Explanation

An attempt was made to enable the cloud snapshot function while the volume was being migrated between pools.

User response

Wait for the migration operation to finish before you enable cloud snapshots for this volume. Use the management GUI or the **lsmigrate** command to monitor the progress of the migration.

CMMVC8768E Cloud snapshots cannot be enabled because the volume capacity is zero bytes.

Explanation

The cloud snapshot function cannot be used with volumes that have a capacity of zero bytes.

User response

Make sure that you specified the correct volume. If so, expand the size of the volume and retry the command.

CMMVC8769E Cloud snapshots cannot be disabled because there is a cloud snapshot of the volume in progress.

Explanation

An attempt was made to disable the cloud snapshot function while a cloud snapshot was in progress.

User response

Wait for the cloud snapshot operation to complete or cancel the cloud snapshot. Use the management GUI

or the **lsvolumebackupprogress** command to monitor the progress of the cloud snapshot, or the **rmvolumebackupgeneration** command to cancel the cloud snapshot. When the snapshot is no longer in progress, retry the command.

CMMVC8771E The specified parameter lists must be of equal length.

Explanation

The **driveclass** parameter must contain the same number of colon-separated list elements as the **drivecount** parameter.

User response

Validate the command line and retry the command.

CMMVC8772E The command cannot be completed because the I/O group of the drive class has the maximum number of arrays configured.

Explanation

The **mkdistributedarray** command fails because the maximum number of arrays already exists, as configured in the I/O group of the drive class.

Note: Each distributed array occupies 16 slots, starting at an MDisk ID divisible by 16, in the MDisk table. For more information, refer to the documentation for the **lsmdisk** command.

User response

Remove existing arrays in the I/O group before trying the command again.

CMMVC8773E Unable to create the array due to insufficient available drives.

Explanation

The command fails because no drives of the specified drive class in the appropriate drive state are available to create the full array.

Some drives might be available, but not all of the required drives.

Perhaps some drives are not in the candidate state.

Perhaps an enclosure might be offline.

User response

After correcting the drive availability problem for the proper class, use the **lsdriveclass** command or the

lsdriveclass view in the GUI to verify the number of available drives. Then try the command again.

CMMVC8774E An array cannot be created with the drive count, stripe width and rebuild areas entered.

Explanation

The **mkdistributedarray** command fails because the values for the drive count, stripe width, and rebuild areas do not work together.

The drive count value must equal or be greater than the combined value of the stripe width and rebuild areas count.

User response

After determining what the proper values should be, try the command again to create the array.

CMMVC8775E Command cannot be initiated because the distributed array does not have an available rebuild space. Replace failed member drives or swap members occupying rebuild spaces before retrying.

Explanation

The **chararraymember** or the **chdrive** command fails because not enough rebuild space is available.

A distributed array has a limited number of spaces where it rebuilds. The command requires the use of a rebuild space, but there are no free spaces to use.

Replacing failed drives creates space in the array to begin a copyback that copies data back from rebuild space. Replacing failed drives thus frees rebuild space for the command to use.

User response

Verify that the array member ID is correct. Replace failed hardware to free rebuild space. If failing a drive, allow the command to degrade redundancy. Then try the command again.

CMMVC8776E A parameter is not supported for this array type.

Explanation

The **chararraymember** or the **chararray** command fails because you used a parameter that is not supported for the array type (distributed or traditional) to attempt a change that is not supported.

Changes to the `rebuildareasgoal` and `initnewextents` parameters are supported for distributed arrays only.

Changes to the `sparegoal` and `balanced` parameters are supported on traditional arrays only.

User response

Try the command again using parameters that are appropriate for the type of array.

CMMVC8777E The command failed because the maximum number of encryption keys has been reached.

Explanation:

The resources that are needed to create a new key have all been used.

User response:

If your object has an individually selectable encryption attribute, consider selecting the **-encrypt no** option for that object. Otherwise, review all encrypted objects in the system. If possible, free up some existing encrypted objects and then retry the command.

CMMVC8778E The command failed because the object is the last active copy of its volume.

Explanation

The volume must contain at least one copy.

User response

If you must delete the copy, delete the entire volume by using the **rmvolume** command.

CMMVC8779E The provided information was not sufficient to identify a specific volume copy.

Explanation

The command uses one or more of the following criteria to delete a volume copy:

- Site number
- Storage pool
- Copy ID

The command did not specify enough information to uniquely identify the volume copy to be deleted.

User response

Retry the command, providing more information.

CMMVC8780E The volume copy was not deleted because it is part of a FlashCopy mapping.

Explanation

You cannot remove a volume copy that is part of a FlashCopy mapping.

User response

First, verify that you specified the correct volume copy. If not, retry the command with a volume copy that is not part of a FlashCopy mapping.

If you specified the correct volume copy, complete one of the following tasks:

- Remove the FlashCopy mapping and then retry the command.
- Specify the **-removefcmaps** parameter to force-delete the volume copy. This parameter stops any dependent FlashCopy maps and must be used with caution.

CMMVC8810E The volume was not deleted because it is configured as a change volume for a Remote Copy relationship. Either disassociate the volume from the relationship or use -removefcmaps to force delete the volume, which might result in the loss of data.

Explanation

An attempt was made to delete a volume that is configured as the master or auxiliary change volume in a remote copy relationship.

User response

Complete one of the following actions:

- If you entered the wrong volume, correct the command and retry it.
- Remove the volume from the remote copy relationship and retry the command.
- Retry the command with the **-removefcmaps** parameter to force the deletion of the volume.

CAUTION: A forced deletion can result in data loss.

CMMVC8782E The volume copy was not deleted because the copy has an image mode mdisk and a change volume is providing the consistent image.

Explanation

A volume copy cannot be deleted when a change volume is in use.

User response

First, verify that you specified the correct volume copy. If not, retry the command with a volume copy that does not have an image mode MDisk.

If you specified the correct volume copy, complete one of the following tasks:

- Wait for the use of the change volume to complete and then retry the command.
- Specify the **-discardimage** parameter to force-delete the volume copy. A forced deletion can result in data loss on the image mode copy.

CMMVC8783E The volume copy was not deleted because the volume is part of a consistency group.

Explanation

A volume copy cannot be deleted when it is part of an active-active relationship.

User response

First, verify that you specified the correct volume copy. If not, retry the command with a volume copy that is not part of a consistency group.

If you specified the correct volume copy, remove the active-active relationship for the volume from the consistency group, then retry the command.

CMMVC8784E The command failed because an additional feature activation is required for the candidate node

Explanation:

The candidate node requires an additional license before the action can be completed.

User response

Activate the feature for the candidate node and then retry the command.

CMMVC8785E The command failed because the node does not support encryption, and encryption is required in the IO group.

Explanation:

The existing I/O node is capable of encryption. This error occurs when adding an I/O group partner node that does not support encryption.

User response:

Acquire an encryption capable node to add to the I/O group.

CMMVC8786E The node cannot be added because it does not support encryption, and encryption is in use for some SAN MDisks.

Explanation:

Encryption is enabled. An attempt was made to add a node that is not encryption-capable while storage pools were being encrypted that include SAN MDisks that are not self-encrypting.

User response:

Acquire an encryption capable node, or remove all non-self-encrypting SAN MDisks from all encrypting storage pools.

CMMVC8787E The volume was not deleted because it is mapped to a host.

Explanation

You cannot delete a volume that is mapped to a host.

User response

If you specified the wrong volume, retry the command. If you are sure that you want to remove the specified volume, remove the host mapping and retry the command. Alternatively, you can include the **-removehostmappings** parameter with the **rmvolume** command to force the removal of the host mappings.

CAUTION: When you use a "force" parameter such as **-removehostmappings**, you risk loss of data.

CMMVC8788E The volume was not deleted because it is part of Metro Mirror or Global Mirror relationship.

Explanation

You cannot delete a volume that is part of a remote copy relationship.

User response

If you specified the wrong volume, retry the command. If you are sure that you want to remove the specified volume, remove the remote copy relationship and retry the command. Alternatively, you can include the **-removercrelationships** parameter with the **rmvolume** command to force the removal of the remote copy relationship.

CAUTION: When you use a "force" parameter such as **-removercrelationships**, you risk loss of data.

CMMVC8789E The volume was not deleted because it is part of a FlashCopy mapping.

Explanation

You cannot delete a volume that is part of a FlashCopy mapping.

User response

If you specified the wrong volume, retry the command. If you are sure that you want to remove the specified volume, remove the FlashCopy mapping and retry the command. Alternatively, you can include the **-removefcmaps** parameter with the **rmvolume** command to force the removal of the FlashCopy mappings.

CAUTION: When you use a "force" parameter such as **-removefcmaps**, you risk loss of data.

CMMVC8790E The volume was not deleted because it would result in inconsistent data on an image mode mdisk.

Explanation

You cannot delete an image mode volume that has inconsistent data.

User response

If you specified the wrong volume, retry the command. If you are sure that you want to remove the specified volume, wait until the data on the image mode volume is consistent before you retry the command. Alternatively, you can include the **-discardimage** parameter with the **rmvolume** command to force the removal of the volume.

CAUTION: When you use a "force" parameter such as **-discardimage**, you risk loss of data.

CMMVC8791E There is already an outstanding certificate request. Use the -force flag to discard this request and generate a new certificate request.

Explanation:

You issued 'chssystemcert -mkrequest' twice without successfully installing the certificate from the first request that uses 'chssystemcert -install'.

User response

Do one of the following:

- Get the outstanding request signed and install it using 'chssystemcert -install'.

- Abandon the outstanding request and start a new one using 'chssystemcert -mkrequest ... -force'.

Note: If a new request is started, any certificate that is created from a previous request can no longer be used.

CMMVC8792E Cannot install certificate because there is no outstanding certificate request.

Explanation:

You are attempting to install a certificate file using 'chssystemcert -install' without first creating a certificate request. Only a signed certificate that is produced from a certificate request that is created by the system can be installed. Once the certificate has been installed, it cannot be installed again.

User response

Only a signed certificate request can be installed. Use the 'chssystemcert -mkrequest' command to create a certificate request and then get this request signed by a certificate authority (CA). The resulting certificate can then be installed.

CMMVC8793E Cannot install certificate because it has the wrong key.

Explanation

You are attempting to install a certificate file by using 'chssystemcert -install', which is not derived from the outstanding certificate request. Either:

- You tried to install the wrong certificate
- 'mkrequest -force' was used between the certificate request being generated and the installation of the signed certificate.

Note: Get the latest request signed and install this certificate.

User response

Find the correct certificate to install or use the 'chssystemcert -mkrequest -force' command to start a new certificate request.

CMMVC8794E Invalid certificate file.

Explanation:

The certificate file that you are attempting to install cannot be parsed. The certificate must be provided in base64 encoded PEM format.

User response

Check that the certificate to be installed is in the correct format and then copy the file to the system. Attempt to install it again.

CMMVC8795E **This command is no longer supported. Use the CLI command 'chsystemcert' to manage the SSL certificate for the system.**

Explanation:

The CLI command 'chsystem -regensslcert' is no longer supported. A new CLI command 'chsystemcert' that provides more options for managing the SSL certificate for the system, replaced it.

User response

Use the 'chsystemcert' command instead.

CMMVC8796E **Cannot make unencrypted MDisk Group as parent MDisk Group [%1] has an encryption key.**

Explanation:

You are not allowed to make an unencrypted child MDisk Group when the parent MDisk Group has an encryption key.

User response:

The use case is to make an unencrypted child MDisk Group on an encrypted system. You will need to make a new MDisk Group without an encryption key instead.

CMMVC8797E **Unable to change mdisk property while being part of an MDisk Group with an encryption key.**

Explanation:

The MDisk Group and/or one of its child pools has an encryption key that it is using for the MDisk. This can not be changed while the MDisk contains customer data.

User response:

You need to remove the MDisk from the MDisk Group, apply the change in property, and then add back to the MDisk Group.

CMMVC8798E **Cannot add unencrypted MDisk to encrypted MDisk Group**

Explanation:

The user is not allowed to add an unencrypted MDisk to an encrypted storage pool.

User response:

Only MDisks in encrypting I/O groups can be added to an encrypted storage pool.

CMMVC8799E **It is not possible to create an encrypted image disk.**

Explanation:

You are trying to create an image mode disk that would be encrypted.

User response:

Image mode disks can be created in an unencrypted storage pool only.

CMMVC8800E **Cannot migrate as pool storage_pool is encrypted.**

Explanation:

Encrypted data cannot be moved unless the source and destination have the same encryption key.

User response:

Create or add a volume copy and then (auto) delete the source once copied.

CMMVC8801E **Insufficient drive count specified.**

Explanation

The **lspotentialarraysize** command fails when its **drivecount** parameter is less than its **stripewidth** parameter.

The number of drives in the array must be an integer from 3 - 128. The stripe width varies per RAID type:

RAID

Stripe width

R1

2-16

R5

3-16

R6

5-16

R10

Even integers from 2-16

User response

Retry the command with a drive count that is equal to or greater than the stripe width.

CMMVC8802E **The command failed because the parent pool contains an unencrypted external MDisk.**

Explanation:

An attempt was made to create an encrypted child pool where the parent pool has an unencrypted external MDisk and at least one I/O group contains hardware that is not reported as encryption capable. It is not possible for non-encryption-capable nodes to perform encrypted operations.

User response:

Either remove the non-encryption-capable I/O group members from the cluster or create the pool as not encrypted.

CMMVC8803E **Stripe width incorrect for RAID type.**

Explanation

The **lspotentailarraysize** command fails because the stripe width is not good. Valid values are:

RAID

Stripe width

R0

1-8

R1

2

R5

3-16

R6

5-16

R10

Even integers from 2-16

User response

Retry the command with a valid stripe. Use the **lsarrayrecommendation** command to recommend an optimal value.

CMMVC8804E	The number of rebuild areas specified must be greater than or equal to the rebuild area goal parameter.
-------------------	--

Explanation

The command fails because it creates a distributed array with a goal of more rebuild areas than are available in this array.

User response

If you use the **rebuildareas** parameter of the **mkdistributedarray** command, ensure that its value is greater than or equal to the **rebuildareasgoal** parameter value.

If you do not use the **rebuildareas** parameter, but do use the **rebuildareasgoal** parameter, the goal value is greater than the default areas value of 1 for RAID5 or 2 for RAID6. Either reduce the goal or specify a greater areas value than the default.

CMMVC8805E	An array of this RAID level cannot be created using this drive capacity.
-------------------	---

Explanation

The command fails because it cannot create a distributed array with drives that have a capacity exceeding the limit for the RAID level. For example, you cannot create a RAID5 array if the drive capacity is greater than or equal to 8 TB.

User response

Change the RAID level or use drives with a capacity less than the limit for the RAID level, such as 8 TB for RAID5.

CMMVC8806E	The specified drive count exceeds available drives in the drive class.
-------------------	---

Explanation

The **lsarrayrecommendation** command fails because the colon-delimited list of drive counts has a drive count that is greater than the number of available drives in the respective drive class.

User response

Try the command again with each drive count equal to or less than the number of available drives in its respective drive class.

CMMVC8807E	A duplicate drive class ID was entered in the list.
-------------------	--

Explanation

The **lsarrayrecommendation** command fails when the colon-delimited list of drive classes has duplicate IDs.

User response

Try the command again after editing the list of drive classes.

CMMVC8808E	Cannot create the encrypted child pool because the parent pool contains an array that is provided by a non-encryption capable IO group.
-------------------	--

Explanation:

You attempted to create an encrypted child pool where the parent pool contains an array that is provided by an enclosure that does not support encryption.

User response:

Either remove the array from the parent group, create the child pool with a parent pool that doesn't contain such arrays or create the child pool without encryption.

CMMVC8809E	Cannot create the encrypted child pool because the parent pool contains an unencrypted DRAID array.
-------------------	--

Explanation:

You attempted to create an encrypted child pool where the parent pool contains an unencrypted distributed array.

User response:

Remove the array from the parent group or create the child pool without encryption.

CMMVC8810E **The volume was not deleted because it is configured as a change volume for a Remote Copy relationship. Either disassociate the volume from the relationship or use -removefcmaps to force delete the volume, which might result in the loss of data.**

Explanation

An attempt was made to delete a volume that is configured as the master or auxiliary change volume in a remote copy relationship.

User response

Complete one of the following actions:

- If you entered the wrong volume, correct the command and retry it.
- Remove the volume from the remote copy relationship and retry the command.
- Retry the command with the **-removefcmaps** parameter to force the deletion of the volume.

CAUTION: A forced deletion can result in data loss.

CMMVC8811E **The command is not supported for this array type.**

Explanation

Any of the following actions can cause this error message to be displayed:

- Trying to change an array to be encrypted by using the **charray -encrypt** command.
- Trying to change the balanced or spare goal parameters for a distributed array.
- Trying to change the rebuild areas goal or init new extents parameters for a nondistributed array.
- Trying to change the balance parameter for a distributed array member.
- Trying to change a distributed array to use latency mode.
- Trying to create a distributed array in latency mode.
- Running the **lspotentialarraysize** command for RAID0

- Running the **lspotentialarraysize** command for RAID1 if rebuild areas set or for RAID10 if rebuild areas set.

User response

Specify an array of the correct type and retry the command.

CMMVC8812E **The command failed because the existing volume may have only one mirrored copy.**

Explanation

In a HyperSwap topology, the existing volume can have only a single mirrored copy.

User response

Specify a different volume or remove an existing mirrored copy, and then retry the command.

CMMVC8813E **The command failed because the existing volume has mirrored copies in different sites.**

Explanation

In a HyperSwap topology, all of the mirrored copies for the existing volume must have a matching site of 1 or 2 (not 3 or none). This configuration ensures that the existing volume itself has a consistent and well-defined site of 1 or 2.

User response

Ensure that all mirrored copies of the existing volume have a matching site of 1 or 2 and then retry the command.

CMMVC8814E **The command failed because the existing volume has mirrored copies in storage pools whose site is not 1 or 2.**

Explanation

In a HyperSwap topology, all of the mirrored copies for the existing volume must have a matching site of 1 or 2 (not 3 or none). This configuration ensures that the existing volume itself has a consistent and well-defined site of 1 or 2.

User response

Ensure that all mirrored copies of the existing volume have a matching site of 1 or 2 and then retry the command.

CMMVC8815E The command failed because the IO group is not in the same site as the storage pool.

Explanation

The **-iogrp** parameter applies only when you create a HyperSwap volume copy and requires that the system be configured with a HyperSwap topology. The caching I/O group must be in the same site as the storage pool that you specify for the volume copy that you are creating.

User response

Correct the command and retry.

CMMVC8816E The command failed because the specified FlashCopy mapping is controlled by FlashCopy.

Explanation

This command is not valid for an internally controlled FlashCopy map.

User response

Specify a FlashCopy map that is not internally owned and retry the command.

CMMVC8818E The command failed because the volume already has a copy in the specified site. Use the addvdiskcopy command to add a second copy in the same site.

Explanation

An attempt was made to add a volume copy to a site by using the **addvolume** command when the volume already has a copy in the specified site.

User response

Use the **addvdiskcopy** command to create an additional copy in the same site.

CMMVC8819E The volume copy could not be created because the existing source copy is not compressed.

Explanation:

When creating new volume copies, use the **ignoresyncerrors** parameter only when the existing source copy is a compressed copy.

User response

Use the **ignoresyncerrors** parameter for compressed volume copies.

Note: The **ignoresyncerrors** parameter can also help create valid copies of compressed volume copies that were corrupted due to a bug in the compression engine.

CMMVC8870E The volume was not created because a capacity of zero bytes is not allowed for Hyperswap volumes.

Explanation

A HyperSwap volume can only be created with a provisioned capacity greater than zero bytes.

User response

Either specify a non-zero size for the volume or create a different type of volume.

CMMVC8879E I/O group specified is not present.

Explanation

If you must perform discovery by using a specified I/O group, then you must specify a valid I/O group number. An invalid or non-existent I/O group was specified.

User response

Obtain a valid I/O group number by using the management GUI or the **lsiogroup** command.

CMMVC8880E Some of the nodes in the cluster/ specified IO group are not in online state.

Explanation

One or more of the nodes that are part of the specified system or I/O group are not in an active state. You must initiate discovery from all of the nodes in the system or in the specified I/O group.

User response

Check the node status by using the management GUI or the **lsnode** or **lsnodecanister** command, and ensure that all nodes are online before you restart discovery.

CMMVC8881E Discovery cannot be run as the source port ID is invalid for one or more nodes in the system or specified iogroup.

Explanation

Different models or generations of nodes might have different numbers of Ethernet ports. If the system is

created with multiple nodes that have different supported node models, the source port ID that you specify (either by using the management GUI or by using the **detectiscsistorageportcandidate** command) cannot be greater than the highest port ID on any node that is part of the system or specified I/O group.

User response

Check the number of Ethernet node ports present on each node by using the management GUI or the **lsporttip** command. Run discovery again, and this time specify a port ID within the available range.

CMMVC8882E **Some of the specified source Ethernet ports are not configured for iSCSI use.**

Explanation

The Ethernet ports on all nodes in the system or specified I/O group must be in an online state before a backend controller discovery can be initiated through the port. The port can be in one of the following states:

unconfigured

No iSCSI address is assigned to the port.

configured

An IP address is assigned to the port.

User response

Use the management GUI or the **lsporttip** command to identify the Ethernet port on the unconfigured node whose source port ID you specified for discovery. Use the management GUI or the **cfgporttip** command to assign an IP address of the required type (IPv4 or IPv6). Ensure that all required node Ethernet ports are in an online state before you restart discovery.

CMMVC8883E **Link state is inactive for one or more source Ethernet ports in the system or specified IO group.**

Explanation

The link must be active for all node Ethernet ports that are specified with a source port ID. If any of the links are down, you cannot initiate discovery.

User response

Use the management GUI or the **lsporttip** command to identify the node Ethernet port with source port ID whose **link_state** is inactive. Verify that the Ethernet cable is connected to the port for all affected nodes, then restart discovery.

CMMVC8884E **IP type mismatch between IP of source ports and target IP specified.**

Explanation

To establish an iSCSI session, the initiator and target connection endpoints must both have either IPv4 or IPv6 addresses. If you are performing cluster-wide discovery and the specified target IP type is IPv6, then an IPv6 address must be assigned to all of the initiator source ports with the specified port ID. If you are performing I/O-group-specific discovery and the specified target IP type is IPv6, then an IPv6 address must be assigned to all of the initiator source ports in the I/O group with the specified port ID.

User response

Use the management GUI or the **cfgporttip** command to assign IP addresses with an IP type that matches the target IP. Alternatively, you can configure an IP address that matches the IP type of the source ports on the target controller port.

CMMVC8885E **New controller cannot be discovered as limit of managed iSCSI controllers has been reached.**

Explanation

The **detectiscsistorageportcandidate** command found a new controller with no existing established connections after the maximum of 64 iSCSI controllers was reached.

User response

Use the management GUI or the **lscontroller** command to view the list of managed controllers. Identify any controllers that you no longer need to manage. Remove the mdiskgroups that are composed of mdisks that were exported from the identified controller. Use the **rmiscsistorageport** command to remove the unused iSCSI port. After the **lscontroller** command shows fewer than the maximum of 64 controllers, retry the command to discover the new controller. Also, consider how you might consolidate iSCSI storage onto fewer controllers.

CMMVC8886E **The targetip/ targetip6 parameters do not adhere to the standard IPv4/ IPv6 formats.**

Explanation

An IPv4 or IPv6 address was used in a **targetip** or **targetip6** argument that does not adhere to standard IP address format.

User response

Reenter the command, this time using the correct format in the **targetip** or **targetip6** argument. See the following table for accepted formats.

Table 146. Accepted IP address formats	
IP type	IP address list format
IPv4	1.2.3.4
Full IPv6	1234:1234:abcd:0123:0000:0000:7689:6576
Full IPv6, leading zeros suppressed	1234:1234:abcd:123:0:0:7689:6576
IPv6 with zero compression	1234:1234:abcd:123::7689:6576

CMMVC8887E Authentication with target controller using the credentials specified did not succeed

Explanation

The **username** and **chapsecret** arguments that the iSCSI initiator presented do not match the credentials expected by the iSCSI target controller.

User response

Make sure that you specify the correct credentials in the **username** and **chapsecret** arguments.

CMMVC8888E Discovery could not start as a connection could not be established to the backend controller.

Explanation

A problem in the IP network or the iSCSI target controller prevented the login or discovery request from reaching the target controller, or prevented the target controller from responding to the discovery request.

User response

Verify the following conditions:

- The IP network is properly configured
- The target ports are configured
- The target IPs are reachable

CMMVC8889E Discovery could not be completed due to problems at target or initiator.

Explanation

A problem occurred that prevented a successful login or prevented discovery output from the target controller. Possible problems include protocol errors; a transient target, initiator, or network problem; or other errors returned by the target in response to the discovery request.

User response

Correct any configuration problems at the initiator or target. If the problem persists, contact IBM Support.

CMMVC8890E Sessions cannot be established as there are no discovered controllers for the specified id.

Explanation

A row ID was not specified that indicates the target iSCSI name.

User response

Use the management GUI or the **lsiscsistorageportcandidate** command to list the discovered targets and select a valid row ID as an input to the **addiscsistorageport** command.

CMMVC8891E The specified target IP must not refer to the IP of a system management port

Explanation

An IP conflict was detected between IP addresses of source ports and targets. This error prevents discovery requests being sent from one source port to the same or different configured source ports on any node in the cluster.

User response

Use the management GUI or the **lspportip** command to locate any source port IP addresses that are the same as IP addresses configured on the target. Resolve any conflicts and retry discovery.

CMMVC8892E The specified target IP must not refer to an iSCSI port on the system

Explanation

An IP conflict was detected between assigned clustered system IP addresses and target IP addresses. This error prevents discovery requests being sent from one source port to a system management port. The clustered system IP addresses are assigned during cluster creation.

User response

Resolve conflicting IP addresses and retry the command. If necessary, you can use the management GUI or the **lssystemip** command to locate conflicting IP addresses, and use the **chsystemip** command to change system IP addresses.

CMMVC8893E Sessions cannot be established as discovery has not been done through the iogroup specified.

Explanation

Discovery must be done through an I/O group before you can use the **addiscsistorageport** command to establish sessions through that I/O group. You can run the **addiscsistorageport** command with a specific I/O group ID if you previously ran cluster-wide discovery.

User response

Use the management GUI or the **lsiscsistorageportcandidate** command to view the I/O groups through which discovery was done. Use this information to correct the command, and then resubmit it.

CMMVC8894E Limit of max IQN+IP tuples per external iSCSI storage system has been reached.

Explanation

A maximum of 128 unique IQN + IP combinations (tuples) are allowed per controller from the initiating cluster.

User response

Use the management GUI or the **lsiscsistorageport** command to view the list of established sessions. Remove sessions that are no longer required by using the management GUI or the **rmiscsistorageport** command. Retry the **addiscsistorageport** command.

CMMVC8895E Sessions cannot be established as maximum session count per node has been reached.

Explanation

The maximum of 256 initiator sessions per initiator node were established from one or more target controllers. Each invocation of the **addiscsistorageport** command creates an additional session through the nodes in the specified I/O group or cluster.

User response

Use the management GUI or the **lsiscsistorageport** command to check the total number of sessions per node. Use the management GUI or the **rmiscsistorageport** command to remove any sessions that are no longer in use. When the number of sessions is below the maximum, try again to establish the session.

CMMVC8896E One source port cannot have more than one session to the same target IQN through different target ports.

Explanation

One-to-many connectivity from source ports to backend controller target ports can create bottlenecks in the I/O path.

User response

Use the management GUI or the **lsiscsistorageport** command to view the sessions that were established between initiator ports and the target IQN+IP. Create a session to a target IQN that does not already have a connection to a source port.

CMMVC8897E One node cannot have more than one session with same target IQN +IP through different source ports.

Explanation

Many-to-one connectivity from source ports to backend controller target ports can create bottlenecks in the I/O path.

User response

Use the management GUI or the **lsiscsistorageport** command to view the sessions that were established between initiator ports to target IQN+IP. Use a source port for the session that is not already connected to a target IQN.

CMMVC8898E Sessions cannot be torn down as the session does not exist.

Explanation

A valid existing session identifier was not specified for the tear-down.

User response

Use the management GUI or the **lsiscsistorageport** command to list the sessions that are candidates for removal.

CMMVC8901E Enter at least one throttle parameter.

Explanation

No throttle parameters (such as IOPS or bandwidth) were specified.

User response

Specify one or more throttle parameters.

CMMVC8902E Volume is invalid or does not exist.

Explanation

The ID or name of the volume that is to be throttled was not valid or was not found.

User response

Use a valid ID or name for the volume when you retry the command.

CMMVC8903E Throttle is already associated with this volume.

Explanation

The volume ID or name that you specified in a command line parameter is already associated with a throttle value.

User response

Either specify a different ID or name for the volume, or use the **chthrottle** command to change an existing throttle value for the current volume.

CMMVC8904E Throttle parameter missing or invalid.

Explanation

You entered an invalid value for one or more of the parameters, or one or more required parameters are missing, or both.

User response

Verify that all required parameters are specified and that all values are valid, and then retry the command.

CMMVC8905E Offload IO throttle already exists.

Explanation

A throttle exists for offloaded I/O. Only one offloaded I/O throttle can be created for each cluster.

User response

To change the offloaded I/O throttle parameters, use the **chthrottle** command.

CMMVC8906E Throttle object does not exist.

Explanation

The value that you specified for the **throttle_name** parameter was not found.

User response

Retry the command, this time specifying a valid throttle name.

CMMVC8910E The specified IP is a reserved or special IP and cannot be used.

Explanation

The following special or reserved IP addresses cannot be assigned to target controllers:

- Broadcast addresses

Note: Because no subnet mask is specified, the system does not detect the incorrect use of subnet broadcast addresses.

- Multicast addresses
- Unspecified addresses ("0.0.0.0" for IPv4, ":::" for IPv6)
- Loopback addresses
- Link-local addresses

Use APIPA addresses with caution because the system cannot verify them.

User response

Configure a supported IP address on the target controller and retry discovery.

CMMVC8911E Limit of IQNs per target controller has been reached.

Explanation

A maximum of 64 iSCSI Qualified Names (IQNs) per target iSCSI controller is permitted.

User response

Use the management GUI or the **lsiscsistorageport** command to view the sessions for a controller. Remove sessions to IQNs that are no longer in use by using the management GUI or the **rmiscsistorageport** command. Rerun the **addiscsistorageport** command.

CMMVC8912E The specified Ethernet port is not configured for connectivity with external storage systems.

Explanation

The Ethernet port must be configured to allow connectivity to a backend storage controller before you can begin discovery or establish a session through the port.

User response

Use the management GUI or the **cfgportip** command to enable storage system connectivity. Use the **storage** flag for IPv4 addresses and the **storage_6** flag for IPv6 addresses.

.

CMMVC8913E The port IP address cannot be unconfigured as there are active sessions established to backend controller(s) through the port.

Explanation

An attempt was made to remove an IP address from a port that was used to establish backend controller sessions. Removing an IP address through which sessions are established puts mdisks into a degraded state and is not permitted.

User response

Use the management GUI or the **rmiscsistorageport** command to remove sessions through the source port before you remove an IP address that is used for backend controller connectivity. Alternatively, if the intent is only to remove the IP and then configure a new IP, you can achieve the same goal by using the **cfgportip** command with a **-force** flag.

CMMVC8914E Storage flag cannot be reset as the IP is already in use for backend controller(s) connectivity.

Explanation

If you set the **storage** or **storage_6** flag to yes, the IPv4 or IPv6 address for the port can be used to establish connections to the backend iSCSI controller. After you use the **addiscsistorageport** command to establish connectivity from the source port to one or more backend controllers, then you cannot set the **storage** or **storage_6** flag to no unless all the sessions to backend controllers are removed.

User response

Verify the information, make a correction, and resubmit the command.

CMMVC8915E Changing the IP address attributes may cause mdisks to go into a degraded state for some time.

Explanation

If a source IP address is in use for backend controller connectivity, changing the IP address, mask, or gateway causes the existing sessions to be removed and new sessions to be established. During this phase, the managed disks that are visible through the source port that is being reconfigured go into a degraded state until the new sessions are established.

User response

If you did not intend to reconfigure, reenter the command with the correct parameters. If you do want to reconfigure, an administrator can use the management GUI or the **cfgportip** command with the **-force** flag to go ahead with the reconfiguration. Even if no IP address is already assigned to the port that you are trying to use for the **cfgportip** command, use the **-force** flag. No sessions are disconnected because no sessions exist.

CMMVC8919E The command failed because the requested transition is invalid.

Explanation

An invalid transition was attempted, such as from disabled to enabled.

User response

Use multiple steps to make the required transition. For example, move from disabled to transitional to enabled. Refer to the help for specific configuration instructions.

CMMVC8920E The command failed because one or more host ports are currently failed over.

Explanation

A state transition was attempted while a failover was in progress. In practice, this error is rarely seen, due to the requirement that both nodes be online. A small timing window for the error can occur after a node has just unpended and before a controlled node shutdown.

User response

Wait until the **l1targetportfc** command reports that all ports in this I/O group are online on their owner nodes, and then retry.

CMMVC8922E	The command failed because the volume copies would not be in two independent sites.
-------------------	--

Explanation

In a stretched system topology, you can add a volume copy only if the result is a volume copy in each of site 1 and site 2.

User response

Ensure the existing volume copy has a well defined **site** argument (site 1 or site 2), and retry by adding the new volume copy to the other site.

CMMVC8923E	The command failed because a volume in a Metro Mirror or Global Mirror relationship cannot have copies in two sites using HyperSwap.
-------------------	---

Explanation

In a HyperSwap system topology, you cannot add a volume copy to a different site if the existing volume is in a Metro Mirror or Global Mirror relationship.

User response

If you specified the wrong volume, correct the command and retry. If you do need to add the volume copy to a different site, first remove the Remote Copy relationship by using the **rmrcrelationship** command, then retry the command.

CMMVC8924E	The command failed because the volume already has a copy in the specified site.
-------------------	--

Explanation

In a stretched system topology, a volume copy can be added only if the result is a volume copy in each of site 1 and site 2

User response

Retry by specifying a storage pool with a different site for the new volume copy.

CMMVC8925E	The command failed because the cache state for an image mode volume or copy is corrupt.
-------------------	--

Explanation

The data on the image mode mdisk might be different from the data on the image mode volume.

User response

Use the **recovervdisk** command to acknowledge the volume data loss, then retry the command. Alternatively, specify the **-discardimage** parameter to force the removal of the image mode copy.

CMMVC8926E	The volume copy was not deleted because a change volume is providing the consistent image for a copy on the other site.
-------------------	--

Explanation

An attempt was made to remove an image mode copy of a HyperSwap volume while a change volume was still in use.

User response

Wait until the change volume is no longer in use, then retry the command. Alternatively, specify the **-discardimage** parameter to force the removal of the volume copy, which might result in data loss.

CMMVC8927E	The requested operation cannot be applied to sra_monitor and sra_privileged.
-------------------	---

Explanation

An attempt was made to delete or modify support assistance users by using the **rmuser** or **chuser** commands.

User response

Remove support assistance users by using the **chsra -disable** command.

Note: The **chsra -disable** command removes sra_monitor and sra_privileged users and also disables local and remote support assistance if configured.

CMMVC8928E	User names sra_monitor and sra_privileged are reserved,
-------------------	--

please try again with a different name.

Explanation

An attempt was made to add a user with the reserved name `sra_monitor` or `sra_privileged`.

User response

Pick a different user name and retry the command.

CMMVC8929E	Cannot stop email when support assistance is enabled.
-------------------	--

Explanation

An attempt was made to stop the email service while support assistance is enabled.

User response

Disable support assistance by entering the **`chsra -disable`** command, and then try again to stop the email service.

Note: The **`chsra -disable`** command removes `sra_monitor` and `sra_privileged` users and also disables local and remote support assistance if configured.

CMMVC8930E	The command failed because the support assistance feature has not been enabled.
-------------------	--

Explanation

An attempt was made to enter support assistance commands such as **`chsra -disable`** or **`chsra -updatetoken`** before support assistance was enabled.

User response

Enable support assistance by entering the **`chsra -enable`** command, and then retry the command that failed.

CMMVC8931E	Cannot remove email user of usertype support when support assistance is enabled.
-------------------	---

Explanation

An attempt was made to remove a support-type email user by using a command such as **`rmemailuser`** while support assistance is enabled.

User response

Disable support assistance by using the **`chsra -disable`** command, and then try again to remove the email user.

Note: The **`chsra -disable`** command removes `sra_monitor` and `sra_privileged` users and also disables local and remote support assistance if configured.

CMMVC8932E	Cannot delete email server configurations when support assistance is enabled.
-------------------	--

Explanation

An attempt was made to remove an email server by entering a command such as **`rmemailserver`** while support assistance is enabled.

User response

Disable support assistance by running the **`chsra -disable`** command, and then try again to remove the email server.

Note: The **`chsra -disable`** command removes `sra_monitor` and `sra_privileged` users and also disables local and remote support assistance if configured.

CMMVC8933E	Limit of host clusters has been reached.
-------------------	---

Explanation

An attempt was made to create a host cluster when the maximum number of host clusters had already been created. The maximum number of host clusters is 512.

User response

Remove one or more existing host clusters before you add a new one.

CMMVC8934E	Host already belongs to a host cluster.
-------------------	--

Explanation

An attempt was made to add a host to a host cluster when the host already belongs to another host cluster.

User response

- If you specified the wrong host, retry the command and specify a different host.
- Otherwise, remove the host from the host cluster to which it currently belongs, then retry the command.

CMMVC8935E Host cluster does not exist.**Explanation**

A host cluster was specified that does not exist.

User response

Retry the command with a different host cluster.

**CMMVC8936E Host cluster has shared mappings.
Use -keepmappings or -removemappings flag.****Explanation**

An attempt was made to delete a host cluster that has one or more shared mappings without setting a flag to specify how those mappings are to be treated.

User response

Retry the command and specify one of the following flags:

-removemappings

To delete the shared mappings along with the host cluster.

-keepmappings

To keep the shared mappings as private mappings for the host.

CMMVC8937E Limit of hosts in the host cluster has been reached.**Explanation**

An attempt was made to add a host to a host cluster that is full. A host cluster can include a maximum of 128 hosts.

User response

- Add the host to a different host cluster.
- Alternatively, remove one or more hosts from the host cluster before you add another.

CMMVC8938E Host is not part of the host cluster.**Explanation**

An attempt was made to carry out one of the following actions, specifying a host that did not belong to the specified host cluster:

- Remove the host
- Convert a shared mapping to a private mapping

User response

Retry the command and specify a different host, a different host cluster, or both.

CMMVC8939E Some source Ethernet ports are temporarily unavailable due to failover.**Explanation**

In the case of a node-pend event, the iSCSI IP addresses assigned to node Ethernet ports fail over to the partner node. While the IP addresses are in a failover state, discovery cannot be initiated from the node those addresses are assigned to, even though the node ports show as configured. Discovery can be initiated when the IP addresses fail back. The IP addresses fail back immediately if the node unpend 5 minutes or more after the pend event. If the node unpend less than 5 minutes after the pend event, the IP addresses fail back only after pend time + 5 minutes.

User response

Use the management GUI or the **lsportip** command to verify that the IP addresses failed back to the owning node before retrying discovery.

CMMVC8940E Discovery has not been initiated from nodes of specified site.**Explanation**

The **addiscsistorageport** command was not run with the same site ID argument that was used to run discovery.

User response

Run the management GUI or the **addiscsistorageport** command with the same site ID argument that was used to run discovery with the **detectiscsistorageportcandidate** command.

CMMVC8941E Sessions cannot be added to the target controller due to conflict with existing connectivity or discovery output.**Explanation**

One of the following situations occurred:

- Discovery was run with one value for the **iogroup** parameter and the **addiscsistorageport** command was run with a different value for the **iogroup** parameter.
- Discovery was run with a value for the **iogroup** parameter and the **addiscsistorageport**

command was run cluster-wide (**iogroup** not specified).

- Discovery was run cluster-wide and the **addiscsistorageport** command was run with a value for the **iogroup** parameter.
- Sessions were already established through one I/O group, and the **addiscsistorageport** command was run to add connectivity through another I/O group or cluster-wide.
- Sessions were already established cluster-wide, and the **addiscsistorageport** command was run to add connectivity through an I/O group.
- Sessions were already established through a site, and the **addiscsistorageport** command was run to add connectivity through an I/O group or cluster-wide.
- Sessions were already established through an I/O group or were established cluster-wide, and the **addiscsistorageport** command was run to add connectivity through a site. (You cannot mix I/O groups of different topologies in the same system.)

User response

Run the management GUI or the **addiscsistorageport** command with the same site ID parameter that was used to run discovery with the **detectiscsistorageportcandidate** command.

CMMVC8942E	The volume copy was not deleted because the volume is part of a FlashCopy mapping. All FlashCopy mappings must be removed from the volume before this copy can be deleted.
-------------------	---

Explanation

An attempt was made to remove a volume copy when the volume had FlashCopy mappings.

User response

Remove all FlashCopy mappings from the volume, then try again to delete the copy.

CMMVC8943E	The command failed because the consistent image on an image mode copy is being provided by a FlashCopy map.
-------------------	--

Explanation

An attempt was made to remove an image mode volume or volume copy that is the target of an active (copying) FlashCopy mapping. While the FlashCopy mapping is copying, the data on the image mode

mdisk might be different from the data on the image mode volume.

User response

Wait for the FlashCopy operation to complete, then retry the command. Alternatively, specify the **-discardimage** parameter to force the delete operation, which might result in data loss.

CMMVC8944E	The command failed because the volume already has copies in two sites using HyperSwap. Use the addvdiskcopy command to add a second copy in the same site.
-------------------	--

Explanation

In HyperSwap system topology, the **addvolume** command cannot be used to add a mirrored copy in the same site as an existing volume copy.

User response

Use the **addvdiskcopy** command to add a second copy in the same site.

CMMVC8945E	The command failed because it would allow access to an image mode copy in a Metro Mirror or Global Mirror relationship that does not contain consistent data.
-------------------	--

Explanation

An attempt was made to remove an image mode volume or volume copy that is a secondary in a Metro Mirror or Global Mirror relationship and the data on the volume is not consistent.

User response

Wait for the relationship to synchronize the volume from the primary volume, then retry the command. Alternatively, specify the **-discardimage** parameter to force the delete operation.

CMMVC8946E	The command failed because an image mode copy is not synchronized with the host-accessible copy.
-------------------	---

Explanation

An attempt was made to remove an image mode volume or volume copy, and the data on an image mode copy is not synchronized with the host-accessible copy.

User response

Wait for the volume copy to resynchronize, then retry the command. Alternatively, specify the **-discardimage** parameter to force the delete operation.

CMMVC8947E The target controller is not in the storage layer.

Explanation

The target Storwize controller is configured in the replication layer.

User response

Consider whether the target controller is configured correctly. If appropriate, use the management GUI or the **chsystem -layer storage** command on the target controller to configure the controller in the storage layer. If the target controller is in the correct layer, check that the IP address that you specified points to the correct target. Correct the layer for the target controller or specify the correct IP address and rerun discovery by using the **detectiscsistorageportcandidate** command.

CMMVC8948E Storwize V7000 Gen1 compatibility mode cannot be disabled because the system contains a Storwize V7000 Gen1 enclosure.

Explanation

An attempt was made to disable Storwize V7000 Gen1 compatibility mode. This mode must be enabled on any system that contains Storwize V7000 Gen1 enclosures alongside enclosures. The system contains such a combination, so the request to disable the mode was refused.

User response

If you must disable Storwize V7000 Gen1 compatibility mode, remove the Storwize V7000 Gen1 enclosures from the system and run the command again.

CMMVC8949E Storwize V7000 Gen1 compatibility mode cannot be reenabled.

Explanation

An attempt was made to enable Storwize V7000 Gen1 compatibility mode on a system where it was disabled. This mode cannot be reenabled.

User response

If you specified the wrong system, reenter the command. Otherwise, when a Storwize V7000 Gen1 enclosure is removed correctly, the data is migrated and the enclosure cannot be added back.

CMMVC8950E Storwize V7000 Gen1 compatibility mode cannot be disabled because it is not in use on this system.

Explanation

An attempt was made to disable Storwize V7000 Gen1 compatibility mode on a cluster for which it is not in use. Only Storwize V7000 systems (which can be hybrids) use Storwize V7000 Gen1 compatibility mode.

User response

If you specified the wrong system, retry the command with the correct system.

CMMVC8951E The Storwize V7000 Gen1 control enclosure cannot be added because Storwize V7000 Gen1 compatibility mode is not enabled.

Explanation

An attempt was made to add a Storwize V7000 Gen1 control enclosure to a system where Storwize V7000 Gen1 compatibility mode is disabled.

User response

Retry the command, and this time specify a enclosure. Alternatively, add the Storwize V7000 Gen1 enclosure to a system where it is accepted.

CMMVC8952E The action failed because there was a mismatch with authentication credentials previously specified for same target.

Explanation

The **addiscsistorageport** command configures a session between an initiator port and target IP addresses for a target iSCSI Qualified Name (IQN). If you run the command again for the same target parameters, it returns successfully without initiating any action as the sessions was established after the first invocation. However, if you retry the command with a different **username** argument, **chapsecret** argument, or both, then the command fails because the initiator cannot verify which credentials are correct.

User response

To change the target credentials, complete the following steps by using the GUI or the specified command:

1. Use the **lsscsistorageport** command to list the previous set of sessions that were established.
2. Use the **rmiscsistorageport** command to remove the sessions that match the source port, IP address, and IQN for the target.
3. Initiate a new discovery and establish sessions with new credentials.

CMMVC8953E There are no nodes in the site and/or I/O group specified.

Explanation

Nodes in the cluster were not configured to be part of the site before discovery of the iSCSI backend controller was initiated.

User response

If the system topology is a stretched cluster or HyperSwap configuration, use the management GUI or the **addnode** or **chnode** command to add the nodes to the specified site. Restart discovery.

CMMVC8954E The system is not in the replication layer.

Explanation

You can initiate discovery from a system in the replication layer only.

User response

Consider whether the source system is configured correctly. If appropriate, use the management GUI or the **chsystem -layer replication** command on the source system to configure the system in the replication layer. Rerun discovery by using the **detectiscsistorageportcandidate** command.

CMMVC8956E The command failed because the volume is the auxiliary volume in an active-active relationship.

Explanation

The specified volume is an auxiliary volume in an active-active Remote Copy relationship. You cannot throttle an auxiliary volume.

User response

Specify a different volume or break the Remote Copy relationship before you create or modify the throttle on this volume.

CMMVC8957E The command failed because the volume specified does not exist.

Explanation

A volume ID or name was specified that does not exist.

User response

View the list of volumes by means of the GUI or the **lsvdisk** command to ensure that you specified the correct volume ID or name. For a HyperSwap volume involved in an active-active relationship, the volume ID and name are the same as those of the master volume.

CMMVC8958E The command failed because the volume has vvol ownership and may not have copies in two sites using HyperSwap.

Explanation

A volume created as a VVol may not be created as, or converted to, a HyperSwap volume that is involved in an active-active relationship.

User response

Use a different volume as a HyperSwap volume.

CMMVC8959E The command failed because the master volume has vvol ownership and may not participate in a Remote Copy relationship.

Explanation

A volume created as a VVol cannot participate in a Remote Copy relationship as the master or auxiliary volume.

User response

Use VMware vCenter to manage system objects like volumes and pools.

CMMVC8960E The command failed because the specified node is the last node of the cluster.

Explanation

Only one node is left in the system. If this node leaves the system, the system is removed and cannot process

the command. This error never occurs with **-action replace**.

User response

To put the last node of the system into service state, run **satask startservice**. This command does not run at the system level. The last node of a system cannot be exchanged with a spare.

CMMVC8961E The action failed because the node hardware is incompatible with the previous node.

Explanation

A candidate node has the same World Wide Node Name as the node that you are trying to swap, but is a different node type, or has a different hardware configuration.

User response

Change your Fibre Channel configuration, and then retry the command.

CMMVC8962E The action failed because the specified node is not online.

Explanation

An attempt was made to run the **swapnode -action service** command on a node that is not online.

User response

First, make sure that you specified the correct node. If not, retry the action and specify an online node.

If you specified the correct node, then no further action is required because the node is already offline.

CMMVC8964E The command failed because the support assistance feature has already been enabled.

Explanation

The **chsra -enable** command was entered when support assistance was already enabled.

User response

Enter the **chsra -updatetoken** command to update the shared token or enter the **chsra -disable** command to disable support assistance.

CMMVC8965E The command failed because volumes are dependent on the specified node and -

permitofflinevolumes was not specified.

Explanation

Performing this operation may cause a host I/O outage. This error never occurs with **-action replace**.

User response

Correct the redundancy issue, or, if an I/O outage is acceptable, retry the command with the **-permitofflinevolumes** parameter.

CMMVC8966E This node cannot be added to the IO Group due to having lower configured RAM than required.

Explanation

An attempt was made to add a node to an I/O group where the other nodes in the group have more memory than the added node. It is also possible that faulty RAM is preventing the amount of memory in the node from being correctly detected. All nodes in an I/O group must have the same amount of configured RAM.

User response

Add the node to a different I/O group or increase its memory to match that of the other nodes in the group and retry the command.

CMMVC8967E The command failed because the auxiliary volume has vvol ownership and may not participate in a Remote Copy relationship.

Explanation

A volume created as a VVol cannot participate in a Remote Copy relationship as the master or auxiliary volume.

User response

Use VMware vCenter to manage system objects like volumes and pools.

CMMVC8968E This operation cannot be completed because iSCSI Initiator sessions are present.

Explanation

The operation is not permitted when iSCSI initiator sessions are present and you try to make one of the following changes:

- Changing from the replication layer to the storage layer on a system that is acting as an iSCSI initiator

- Changing from the storage layer to the replication layer on a system that is acting as an iSCSI target

User response

Follow these steps to remove the initiator sessions:

1. Use the management GUI or the **lsiscsistorageport** command to identify the iSCSI initiator sessions on the system that is acting as an iSCSI initiator.
2. Use the management GUI or the **rmiscsistorageport** command to remove all iSCSI initiator sessions.
3. After you remove all initiator sessions, retry the command.

CMMVC8969E This operation cannot be completed because migration to different parent storage pool is not supported.

Explanation

You cannot migrate volumes from a child storage pool to a different parent storage pool or to a child storage pool that has a different parent than the source.

User response

First migrate the volume from the child pool to its own parent, then migrate it from that parent pool to that of a different parent.

CMMVC8970E The storage pool was not deleted because there are volumes associated with the storage pool. A forced deletion is required.

Explanation

You cannot delete a storage pool that has any volumes still associated with it.

User response

Remove the associated volumes and retry the command, or use the **-force** flag:

```
rmmdiskgrp -force storage_pool
```

where *storage_pool* is either the name or the ID of a storage pool.

CAUTION: Use of the **-force** flag can result in data loss. Contact IBM Support before using this flag.

CMMVC8971E The command failed because data in the cache has not been committed to disk.

Explanation

The command failed because data in the cache has not been committed to disk.

User response

Check your command to ensure you have specified the correct volume and target. Make the correction and resubmit the command. Otherwise, investigate why the data has not been committed and how the data must be committed.

CMMVC8972E The command failed because the MDisk is an array.

Explanation

An attempt was made to change the encryption settings of an MDisk that is an array. The **chmdisk** command applies only to external MDisks.

User response

You cannot directly convert the array from unencrypted to encrypted or vice versa. Instead, you must complete one of the following actions:

- Specify a different MDisk and retry the command.
- Delete and re-create the array with the new encryption setting.

CMMVC8973W The IO group *io_group_name* has been restored with ID *new_id* instead of *old_id*.

Explanation

This situation can occur when the configuration node is different from the node that was used to create the original cluster. This change affects the SCSI Inquiry value for the I/O group.

User response

This message is a warning only. No user response is required.

CMMVC8974E The action failed because of incompatible code.

Explanation

The code version on one or more nodes is incompatible with the new version.

User response

Refer to the compatibility requirements for the code version you are adding. Update the cluster to meet the

compatibility requirements, and then perform the upgrade.

CMMVC8975E The node could not be added because of incompatible code. The status code is *status_code* .

Explanation

An attempt was made to add a node with code that has a different revision level than the code in the cluster.

User response

Update the code on the rejected node to the same level as that on the cluster to which it will be added, and then resubmit the command.

CMMVC8976E The cluster was not modified because the IP address is not valid.

Explanation

An attempt was made to change the IP address of a cluster to an address that is not valid.

User response

Correct the address and reissue the command.

CMMVC8977E The action failed because the directory that was specified was not one of the following directories: /dumps, /dumps/iostats, /dumps/iotrace, /dumps/feature, /dumps/config, /dumps/elems, /dumps/ec or /dumps/pl.

Explanation

An attempt was made to clear a file from, or copy a file to, a directory that is not valid.

User response

Ensure that the command accesses a valid directory and try again.

CMMVC8978E The action failed as the resulting disk size would be less than, or equal to, zero.

Explanation

An attempt was made to shrink a disk, however the resulting size would have been less than or equal to zero.

User response

Check your command to ensure that you have the correct disk size. You can also check the **shrinkvdiskspace** command documentation for additional information. Make the correction and resubmit the command.

CMMVC8979E The action failed as the resulting disk size would be less than, or equal to, zero.

Explanation

An attempt was made to shrink a volume to a size that is below the permitted minimum.

User response

Check your command to ensure that you have the correct disk size. Make the correction and resubmit the command. For more information, see the documentation for the **shrinkvdiskspace** command.

CMMVC8980E Metadata recovery can not use the provided MDisk id - invalid or destroyed.

Explanation

Metadata recovery cannot use the provided MDisk ID, which is not valid or refers to a disk that was destroyed.

User response

Correct the specified MDisk and resubmit the command.

CMMVC8981E The update failed as a file containing the code for the specified MCP version was not found.

Explanation

Two files are required to successfully complete a code update. One file contains the files that make up the base operating system, and the other file contains the code. This message appears if the OS version is incompatible with the code.

User response

Upload two compatible files and resubmit the command.

CMMVC8982E The action failed because the volume is part of a Remote Copy relationship.

Explanation

An action was performed against a volume that is part of a Remote Copy relationship.

User response

Remove the volume from the Remote Copy relationship and then resubmit the command.

CMMVC8983E The action failed because the volume is part of a FlashCopy mapping.

Explanation

An action was performed against a volume that is part of a FlashCopy mapping.

User response

Remove the volume from the FlashCopy mapping before reissuing the command.

CMMVC8984E The FlashCopy mapping or consistency group could not be started in a reasonable time. The mapping or group is instead being prepared.

Explanation

The FlashCopy mapping or consistency group could not be started in a reasonable time. The mapping or group is instead being prepared.

User response

Resubmit the command.

CMMVC8985E The command has failed because a virtual medium error exists on the image mode volume or copy.

Explanation

When you submit this command, you cannot specify an image mode volume that has a virtual medium error on the volume or on any copy of the volume because the medium errors cannot be maintained on the ejected MDisk image copy.

User response

If an exact image copy is required, ensure that there is no virtual medium error on the image mode volume that you specify or on any of its copies, and resubmit the command.

If an exact copy is not required, you can use the -force option of the command, but all of the virtual medium errors will be lost.

2084 Spectrum Virtualize for SAN Volume Controller, FlashSystem, and Storwize Family: Command-Line Interface User's Guide

CMMVC8986E The command failed as a migrate to image was in progress.

Explanation

An attempt was made to execute a command against a volume that was involved in a migrate to image operation.

User response

Wait for the migration to complete and reissue the command.

CMMVC8987E You are trying to recover region data that was created by a code level different from the one you are currently running on the node.

Explanation

You are trying to recover region data that was created by a code level different from the one you are currently running on the node.

User response

Inform your administrator of this error. You might need to update the code level on your server. Wait until the server is updated before you resubmit the command.

CMMVC8988E Failed to recreate the cluster you are trying to rebuild.

Explanation

An attempt was made to rebuild a cluster, but the attempt failed.

User response

Check your command. The source and target names might not match. Make the correction and resubmit the command.

CMMVC8989E The FlashCopy mapping was not created or modified because the consistency group already contains the maximum number of mappings.

Explanation

An attempt was made to create a FlashCopy mapping in, or move a FlashCopy mapping to, a consistency group that has the maximum number of FlashCopy mappings that it can contain.

User response

Create or move the FlashCopy mapping to another consistency group or remove an existing FlashCopy mapping from the desired group and then reissue the command.

CMMVC8990E The Remote Copy relationship was not created because the master or auxiliary volume is a member of a Remote Copy relationship.

Explanation

An attempt was made to create an active-active relationship with a volume copy in another site. This relationship is not supported if the volume is already in a remote copy relationship.

User response

Make sure that you specified the correct volume. If so, delete the existing relationship and try again.

CMMVC8991E The maximum number of hosts for the cluster is already configured.

Explanation

You must remove at least one host definition before you can resubmit the command.

User response

Determine whether the action is required.

If the action is required, review the current configuration to determine whether any current host definitions are not required. Remove at least one host definition that is not required, and resubmit the command.

CMMVC8992E The maximum number of host/IO group pairs for the cluster is already configured.

Explanation

You must remove at least one host I/O group pair definition before you can resubmit the command.

User response

Determine whether the action is required.

If the action is required, review the current configuration to determine whether any current host I/O group pair definitions are not required. Remove at least one host I/O group pair definition that is not required, and resubmit the command.

CMMVC8993E The maximum number of WWPNs plus iSCSI qualified names (IQNs) for the cluster is already configured.

Explanation

The command cannot be initiated because the maximum number of WWPNs plus iSCSI qualified names for the cluster has been reached.

User response

Determine whether the action is required.

If the action is required, review the current configuration to determine whether any current WWPN or iSCSI qualified name definitions are not required. Remove at least one WWPN definition or iSCSI qualified name that is not required, and resubmit the command.

CMMVC8994E The maximum number of hosts for one or more IO groups is already configured.

Explanation

You must remove at least one host I/O group pair definition from the I/O group that you have specified before you can resubmit the command.

User response

Determine whether the action is required.

If the action is required, review the current configuration to determine whether any current host I/O group pair definitions for the I/O group that you have specified are not required. Remove at least one host I/O group pair definition that is not required from the I/O group that you have specified, and resubmit the command.

CMMVC8995E The maximum number of WWPNs for one or more IO groups is already configured.

Explanation

You must remove at least one WWPN definition from the I/O group that you have specified before you can resubmit the command.

User response

Determine whether the action is required.

If the action is required, review the current configuration to determine whether any current WWPN definitions for the I/O group that you have specified

are not required. Remove at least one WWPN definition that is not required from the I/O group that you have specified, and resubmit the command.

CMMVC8996E The maximum number of WWPNs for the host is already configured.

Explanation

You must remove at least one WWPN definition for the host that you have specified before you can resubmit the command.

User response

Determine whether the action is required.

If the action is required, review the current configuration to determine whether any current WWPN definitions for the host that you have specified are not required. Remove at least one WWPN definition that is not required for the host that you have specified and resubmit the command.

CMMVC8997E The host does not belong to one or more of the IO groups specified or inferred.

Explanation

The host does not belong to one or more of the I/O groups specified or inferred.

User response

Specify a host and I/O group combination that is currently defined, and resubmit the command.

CMMVC8998E The host already belongs to one or more of the IO groups specified.

Explanation

The host already belongs to one or more of the I/O groups specified.

User response

Check your command. Change the host name if applicable and resubmit the command.

CMMVC8999E An IO group cannot be removed from a host because of one or more associated volumes.

Explanation

An I/O group cannot be removed from a host because of one or more associated VDisks.

User response

Check your command and ensure that you have specified the correct I/O group. Make the correction if one is needed and resubmit.

CMMVC9000E The action was not completed because the cluster has reached the maximum number of extents in storage pools.

Explanation

The cluster reached the maximum number of extents in the storage pool; therefore, the action did not complete. An attempt was made to use additional extents, for example by creating or expanding a volume. The action cannot be initiated because it would cause the maximum number of extents for a cluster to be exceeded.

User response

Free up extents by deleting other volumes, and resubmit the command.

CMMVC9001I The package installed successfully.

Explanation

The package installed successfully.

User response

This message is for your information only. No response is required.

CMMVC9002E The cluster was recovered and the CLI functionality is limited until the cause of the failure is determined and any corrective action taken. Contact technical support for assistance.

Explanation

The cluster was recovered and the CLI function is limited.

User response

Contact IBM Support.

CMMVC9003E The action failed as the SSH key has been revoked.

Explanation

The action failed because the SSH key was revoked.

User response

Check your command and correct the number that you specified for the SSH key. Resubmit after you make the correction.

CMMVC9004E The action failed as the SSH key index (SSH_LABEL_ID) is invalid.

Explanation

The action failed because the SSH key index (SSH_LABEL_ID) is not valid.

User response

Correct the SSH key index and retry the command.

CMMVC9006E This operation cannot be performed because the cluster is currently cancelling the previous update command.

Explanation

This operation cannot be performed at the same time that the previous update command is being canceled.

User response

Wait until the previous update command stops running and resubmit the command.

CMMVC9007E This operation cannot be performed because, either an update has not been started, or an update is in progress but is not in a state where it can be aborted.

Explanation

This operation cannot be performed because the update is progressing.

User response

Wait until the update finishes and resubmit your command.

CMMVC9008E The update cannot be cancelled because at least one node has already committed to a new code level.

Explanation

You cannot cancel the update because one or more nodes already committed to a new code level.

User response

Contact IBM Support.

CMMVC9009E An invalid response has been entered. The command has not been executed. Input is case sensitive. Enter either yes or no.

Explanation

A response that is not valid was entered. The command was not run.

User response

Enter either yes or no.

CMMVC9010E The command has not completed. A limited availability parameter has been entered without the required environment setting being set.

Explanation

The command did not finish. A limited availability parameter was entered without the required environment setting.

User response

Check your command. If the command is correct, contact your administrator to determine whether you need an environment setting so that the command can run. Resubmit the command when the problem is resolved.

CMMVC9011E The command failed as the remote cluster does not support global mirror.

Explanation

The command failed because the remote cluster does not support Global Mirror.

User response

Check your command and ensure that you specified the correct cluster. Make the correction and resubmit the command. If you specified the correct cluster, research why it does not support Global Mirror.

CMMVC9012E The copy type differs from other copies already in the consistency group.

Explanation

The copy type differs from other copies already in the consistency group.

User response

Ensure that the copy type of the mapping that you are attempting to add is the same copy type as the mappings in the consistency group to which you are attempting to add the mapping, and resubmit the command.

CMMVC9013E **The FlashCopy mapping was not prepared because the mapping or consistency group is in the stopping state. The mapping or consistency group must first complete the stop operation and then be prepared**

Explanation

You cannot prepare a FlashCopy mapping or consistency group when the FlashCopy mapping or consistency group is in the stopping state. If you want to prepare a FlashCopy mapping or consistency group, the FlashCopy mapping or consistency group must be in the Stopped or idle_or_copied state.

User response

Wait until the FlashCopy mapping or consistency group reaches the Stopped or idle_or_copied state and then resubmit the command.

CMMVC9014E **The properties of the FlashCopy mapping were not modified because the mapping or consistency group is in the stopping state.**

Explanation

You cannot modify the consistency group of a FlashCopy mapping when the FlashCopy mapping is in the stopping state. If you want to modify the consistency group of a FlashCopy mapping, the FlashCopy mapping must be in the Stopped or idle_or_copied state.

User response

Wait until the FlashCopy mapping reaches the Stopped or idle_or_copied state and then resubmit the command.

CMMVC9015E **The FlashCopy mapping was not deleted because the mapping or consistency group is in the stopping state. The mapping or consistency group must be stopped first.**

Explanation

You cannot delete a FlashCopy mapping or consistency group when the FlashCopy mapping or consistency group is in the stopping state. If you want to delete a FlashCopy mapping or consistency group, the FlashCopy mapping or consistency group must be in the Stopped or idle_or_copied state.

User response

Wait until the FlashCopy mapping or consistency group reaches the Stopped or idle_or_copied state and then resubmit the command.

CMMVC9016E **The FlashCopy mapping or consistency group was not started because the mapping or consistency group is in the stopping state. The mapping or consistency group must first complete the stop operation and then be prepared.**

Explanation

You cannot start a FlashCopy mapping or consistency group when the FlashCopy mapping or consistency group is in the stopping state. If you want to start a FlashCopy mapping or consistency group, the FlashCopy mapping or consistency group must be in the Prepared state.

User response

Wait until the FlashCopy mapping or consistency group reaches the Stopped or idle_or_copied state and then prepare the FlashCopy mapping or consistency group before you start it.

CMMVC9017E **The FlashCopy mapping or consistency group was not stopped because the mapping or consistency group is already in the stopping state.**

Explanation

A Stop FlashCopy mapping or consistency group task was already submitted and is still in progress. When the task completes successfully, the FlashCopy mapping or consistency group state changes to Stopped.

User response

Wait for the existing task to complete. The group state changes to Stopped automatically.

CMMVC9018E **The FlashCopy mapping was not created because the source**

volume cannot be the target for a FlashCopy mapping.

Explanation

A volume cannot simultaneously be both the source of a FlashCopy mapping and the target of a FlashCopy mapping. A source volume was specified that is currently defined as the target of a FlashCopy mapping.

User response

You have two options. One option is to specify a different source volume and resubmit the command. The other option is to delete the existing FlashCopy mapping that defines the source volume that was specified as the target volume, and resubmit the command.

CMMVC9019E	The FlashCopy mapping was not created because the source virtual disk (VDisk) is already in the maximum number of FlashCopy mappings.
-------------------	--

Explanation

The number of FlashCopy mappings in which a volume can be defined as the source volume is limited. The source volume that was specified cannot be defined to another FlashCopy mapping because it is already defined as the source volume to the maximum number of FlashCopy mappings.

User response

You have two options. One option is to specify a different source volume and resubmit the command. The other option is to delete one of the existing FlashCopy mappings that contains the source volume and resubmit the command.

CMMVC9020E	The FlashCopy mapping was not created because the target volume is already a source volume in a FlashCopy mapping.
-------------------	---

Explanation

A volume cannot simultaneously be both the source of a FlashCopy mapping and the target of a FlashCopy mapping. The target volume that was specified is currently defined as the source of a FlashCopy mapping.

User response

You have two options. One option is to specify a different target volume and resubmit the command.

The other option is to delete all of the existing FlashCopy mappings that contain the target volume that was specified and resubmit the command.

CMMVC9021E	The FlashCopy mapping was not created because the target virtual disk (VDisk) is already a target VDisk in a FlashCopy mapping.
-------------------	--

Explanation

A volume cannot simultaneously be the target of more than one FlashCopy mapping. The target volume that was specified is currently defined as the target of another FlashCopy mapping.

User response

You have two options. One option is to specify a different target volume and resubmit the command. The other option is to delete the existing FlashCopy mapping that contains the target volume that was specified and resubmit the command.

CMMVC9022E	The command failed because the authorization table is full.
-------------------	--

Explanation

The command failed because the authorization table is full.

User response

Check with your administrator to verify the status of the authorization table. You must wait until the table is adjusted to resubmit the command.

CMMVC9023E	The command failed because the authorization record was not found or is already set to the default role.
-------------------	---

Explanation

The command failed because the authorization record was not found or is already set to the default role.

User response

Check your command for the role you specified. If the role is not set up, check with your administrator to verify the status. Resubmit the command after the role is set up in the system.

If you want to set the role as the default, no further action is required.

CMMVC9024E	The command failed because the authorization record is not set to
-------------------	--

the default role. Use **rmauth** to set the default role.

NOTE This command must specify an admin key.

Explanation

The command failed because the authorization record is not set to the default role.

User response

Use the **rmauth** command to set the default role.

CMMVC9025E The command failed because the specified role was not found.

Explanation

The command failed because the specified role was not found.

User response

Check the command and correct the specified role. If you believe the specified role exists, check with your administrator for clarification. Make the correction and resubmit the command.

CMMVC9026E The command failed authorization because the session SSH key is invalid or was deleted.

Explanation

The command failed authorization because the session SSH key is not valid or was deleted.

User response

Check the command and ensure that you specified a valid SSH key. Make the correction and resubmit the command.

CMMVC9027E The task has failed because the user's role is not authorized to submit the command.

Explanation

One example of a user role restriction is that a user that has a role of Monitor cannot create a volume.

User response

Either log in as a user that has a role that is authorized to submit the task or change the role of the user account that you are using to a role that is authorized to submit the task, and resubmit the task.

CMMVC9028E The command failed because the specified SSH key was not found.

Explanation

The command failed because the specified SSH key was not found. This command must specify an admin key.

User response

Recheck your command and ensure that you specified admin as the SSH user name. Make the correction and resubmit.

CMMVC9029E The command cannot set the authorization record to the default role. Use rmauth to set the default role.

Explanation

The command cannot set the authorization record to the default role.

User response

Use the **rmauth** command to set the default role.

CMMVC9030E The command failed because the SSH key already exists or there is a duplicate SSH key.

Explanation

An attempt was made to add an SSH key that already exists. A different authorization level might be associated with the key.

User response

If the existing SSH key of the same type does not have the authority level that you require, add a different SSH key.

CMMVC9031E The command failed because one of the nodes in the specified I/O group was offline when a memory change was attempted.

Explanation

All nodes in the I/O group must be online when you enter the **chlogrp** command. This error indicates that at least one node is not currently online.

User response

Check the status of the nodes by using the **lsnodecanister** command for enclosure-based systems or the **lsnode** command for appliance-based

systems. If any node in the specified I/O group is not currently online, follow maintenance procedures for that node. When all nodes are online, repeat the command.

CMMVC9032E The Add E-mail User operation failed because there is no space left in the user list.

Explanation

The maximum number of email recipients is already configured.

User response

Remove an existing email recipient and retry.

CMMVC9033E The operation failed because there is already a user with that name.

Explanation

An email recipient with that address already exists.

User response

Make sure that you specified the correct user name. If not, make the correction and try again.

CMMVC9034E The operation failed because the specified user does not exist.

Explanation

An attempt was made to perform an operation on a user that does not exist.

User response

Retry the command with an existing user.

CMMVC9035E The Remove E-mail User operation failed because this is the last entry in the user list.

Explanation

Email services require that at least one participant is configured.

User response

Run the **stopemail** command to stop email services and then remove the email user.

CMMVC9036E Sendmail error EX_USAGE. A command or configuration line has been used incorrectly.

Explanation

The send email task failed because a command or a configuration line was used incorrectly.

User response

Ensure that the email settings are correct and resubmit the task.

CMMVC9037E Sendmail error EX_DATAERR. Address is wrong, or the message is too large for the mailbox.

Explanation

The send email task failed because the message sent is too large or a recipient address is incorrect.

User response

Ensure that all addresses are correct and that the message is not too large, and resubmit the task.

CMMVC9038E Sendmail error EX_NOINPUT. An input file (not a system file) did not exist or was not readable.

Explanation

The send email task failed because a file is missing or cannot be read.

User response

Ensure that the email system is configured correctly. Ensure that access permissions are specified correctly for all email configuration files. Resubmit the task.

CMMVC9039E Sendmail error EX_NOUSER. The sendmail command could not recognize a specified user.

Explanation

The send email task failed because the user and domain combination that you specified does not exist.

User response

Specify a defined user and domain combination, and resubmit the task.

CMMVC9040E Sendmail error EX_NOHOST. The sendmail command could not recognize the specified host name.

Explanation

The send email task failed because the host is not known to the email system.

User response

Ensure that you configured the SMTP environment correctly and that you specify a defined host. Resubmit the task.

CMMVC9041E Sendmail error EX_UNAVAILABLE. A required system resource is not available.

Explanation

The send email task failed because a required system resource is not available.

User response

Ensure that you configured the SMTP environment correctly, and then resubmit the task.

CMMVC9042E Sendmail error EX_SOFTWARE. An internal error occurred (including bad arguments).

Explanation

The send email task failed because an incorrect parameter or parameter value was detected.

User response

Ensure that you configured the SMTP environment correctly. Specify only supported parameters and parameter values, and resubmit the task.

CMMVC9043E Sendmail error EX_OSERR. A system resource error prevented the sending of an email.

Explanation

The send email task failed because a system resource error occurred.

User response

Ensure that you configured the SMTP environment correctly and resubmit the task.

CMMVC9044E Sendmail error EX_OSFILE. Failed to open a critical system file.

Explanation

The send email task failed because a required system file cannot be opened.

User response

Ensure that the email system is configured correctly, and that access permissions are specified correctly for all email configuration files. Resubmit the task.

CMMVC9045E Sendmail error EX_CANTCREAT. An output file could not be written to by sendmail.

Explanation

The send email task failed because the system cannot write to a required output file.

User response

Ensure that the email system is configured correctly, and that access permissions are specified correctly for all email configuration files. Resubmit the task.

CMMVC9046E Sendmail error EX_IOERR. A system I/O error occurred during a sendmail operation. This could be due to a disk failure.

Explanation

The send email task failed because a write or read I/O operation failed. This error might be caused by a disk device failure.

User response

Correct the root cause of the I/O failure, and resubmit the task.

CMMVC9047E Sendmail error EX_TEMPFAIL. The sendmail command could not create a connection to a remote system.

Explanation

The send email task failed because the sendmail application cannot establish a connection to the remote system.

User response

Ensure that the network connection to the remote system is functioning correctly, and resubmit the task.

CMMVC9048E Sendmail error EX_PROTOCOL. The remote system returned something that was incorrect during a protocol exchange.

Explanation

The send email task failed because an error occurred in the protocol exchange.

User response

Ensure that the email system is configured correctly and that you configured the SMTP environment correctly. Resubmit the task.

CMMVC9049E Sendmail error EX_NOPERM. The user does not have permission to perform the requested operation.

Explanation

The send email task failed because the User ID does not have authorization to submit the task.

User response

Ensure that authorizations for your User ID in the email and SMTP configurations are correct, and resubmit the task.

CMMVC9050E Sendmail error EX_CONFIG. There is a fatal problem with the sendmail configuration.

Explanation

The send email task failed because the sendmail configuration is not correct.

User response

Ensure that the email system is configured correctly and that you configured the SMTP environment correctly. Resubmit the task.

CMMVC9051E An unknown error occurred. Ensure your SMTP server is running.

Explanation

The send email task failed because an unexpected error occurred.

User response

Ensure that the SMTP server is running, and resubmit the task.

CMMVC9052E The email command timed out. Check your email server settings as listed on the cluster.

Explanation

The send email task failed because a command timeout occurred.

User response

Ensure that your system settings match those that are recommended in the sendmail application documentation, and resubmit the task.

CMMVC9053E The email service has not been enabled.

Explanation

The send email task failed because the email application is not enabled.

User response

Enable the email application by using the **startemail** command and resubmit the task.

CMMVC9054E The user specified does not exist.

Explanation

You must specify a User ID that exists.

User response

Ensure that the User ID that you specify is defined, and resubmit the task.

CMMVC9055E The command failed because a target volume has dependent FlashCopy mappings.

Explanation

The target volume of the FlashCopy mapping, or the target volume of at least one of the FlashCopy mappings in the consistency group, has other FlashCopy mappings that are dependent on the data on the target volume.

User response

Use the **lsvdiskdependentmaps** command and specify the target volume to determine which FlashCopy mappings depend on the target volume. Either wait for these mappings to reach the **idle_or_copied** state, or stop these mappings. Resubmit the command that produced this error.

CMMVC9056E The create failed because the source and target volumes are members of FlashCopy mappings that have different grain sizes.

Explanation

All FlashCopy mappings that are in a tree of connected mappings must have the same grain size. An attempt

was made to create a new FlashCopy mapping that links two existing trees that have different grain sizes.

User response

You have three options.

- Resubmit the command and specify a different source or target volume.
- Delete all of the existing mappings that contain the source volume and resubmit the command.
- Delete all of the existing mappings that contain the target volume and resubmit the command.

CMMVC9061E **Cannot disable key server type because key server objects of this type exist.**

Explanation

An attempt was made to disable a key server type for which a key server end point exists. The end point indicates that the key server type is actively being used for encryption and therefore cannot be disabled.

User response

Verify that you specified the correct key server type. If so, delete all key server objects of this type by using the **rmkeyserver** command and try again.

CMMVC9062E **Cannot disable key server type because it is not currently enabled.**

Explanation

An attempt was made to disable a key server type that is not currently enabled. The **-disable** parameter can only be used to disable a key server type that is currently enabled and has no online key server objects.

User response

Retry the command and specify an appropriate key server type, that is, one that is currently enabled and has no online key server objects.

CMMVC9064E **This host is the only host in the host cluster. The host cluster will lose all of its shared mappings after removing this host. Use -force flag to continue.**

Explanation

An attempt was made to remove the last host in a host cluster that still includes shared mappings. You must

use the **-force** flag in these circumstances, which removes all shared mappings for the host cluster.

User response

If you are sure that you want to delete the host, retry the command and use the **-force** flag.

Note: Use of the **-force** flag can result in unintended loss of data.

CMMVC9065E **Host cluster does not contain any hosts.**

Explanation

An attempt was made to carry out one of the following actions on an empty host cluster:

- Modify the cluster
- Add or remove shared mappings

User response

Make sure that you specified the correct host cluster. If so, add hosts to the host cluster before you modify it, or before you add or remove shared mappings.

CMMVC9066E **Volume already has a shared mapping to the host cluster.**

Explanation

An attempt was made to map a volume to the same host cluster twice.

User response

Correct the volume name and retry the command.

CMMVC9067E **Volume is mapped as a subsidiary LUN (Virtual Volume).**

Explanation

An attempt was made to map a VMware vSphere Virtual Volume to a host cluster. This mapping is not permitted.

User response

Retry the command and use a volume that is not a Virtual Volume.

CMMVC9068E **Hosts in the host cluster have conflicting SCSI ID's for their private mappings.**

Explanation

An attempt was made to create a shared host cluster mapping to a volume, but a host within the host cluster is already privately mapped to that volume.

User response

Make sure that the host mappings are compatible with the mappings for the host cluster and the hosts it contains.

CMMVC9069E **Volume does not have a shared mapping to this host cluster.**

Explanation

An attempt was made to remove a mapping from a volume to a host cluster where the mapping did not exist.

User response

Make sure that you specified the correct volume and host cluster. If not, retry the command with the correct parameters. If so, no further action is necessary because the mapping does not exist.

CMMVC9070E **Either -keepmappings or -removemappings flag must be specified.**

Explanation

An attempt was made to remove a host from a host cluster that has one or more shared mappings, but no flag was set to determine the disposition of the mappings for that host.

User response

Retry the command and specify either the **-keepmappings** flag to retain the existing mappings or the **-removemappings** flag to delete them.

CMMVC9071E **Cannot remove a mapping because it is a shared mapping.**

Explanation

An attempt was made to remove a shared mapping from a host cluster with the **rmvdiskhostmap** command, which removes a single host-volume mapping.

User response

Use the **rmvolumehostclustermap** command to remove a shared mapping from a host cluster.

CMMVC9072E **The host cluster mapping was not created because a volume is already mapped to this host cluster with this SCSI LUN.**

Explanation

A SCSI LUN was specified that was already in use for a volume that is mapped to the current host cluster.

User response

Retry the command, specifying a different SCSI LUN.

CMMVC9073E **The host cluster mapping was not created because this volume is mapped to one of the hosts in the host cluster with a different SCSI LUN.**

Explanation

An incompatible SCSI LUN ID was specified for the mapping. Hosts within the host cluster have private mappings to volumes with this SCSI LUN.

User response

Retry the command and specify a compatible SCSI LUN ID, that is, an ID that is not in use for private mappings.

CMMVC9074E **The host cluster mapping was not created because this volume is mapped to a host not in this host cluster. Use -force to create the mapping.**

Explanation

An attempt was made to map a volume to a host cluster when that volume is already mapped to another host or host cluster.

User response

Make sure that you specified the correct volume and host cluster. If so, you can retry the command and use the **-force** flag to create the mapping. If you do so, the previous mapping will also be preserved. Always be cautious when you use the **-force** flag, which can have unforeseen consequences.

CMMVC9075E **The host cluster mapping was not created because the limit of mapped volumes supported for a host in this host cluster has been reached.**

Explanation

This error can occur if an attempt is made to map a new volume to a host cluster when one or more of the hosts in the host cluster already have the maximum number of mapped volumes. This error can also occur if an attempt is made to change the host cluster type to **adminlun**, but one of the mappings for one of the hosts in the host cluster has a SCSI LUN that exceeds the maximum for the **adminlun** type. The maximum number of mapped volumes for the default host type is 2048. For the **adminlun** host type, the maximum number of volume mappings that are not mappings to VMware vSphere Virtual Volumes is 512. Thus, the maximum SCSI LUN cannot exceed 512.

User response

Reduce the number of SCSI LUNs by using the **rmvdiskhostmap** command to remove at least one host mapping, then retry the command.

CMMVC9076E	The host cluster mapping was not created because no free SCSI LUN could be found for this shared mapping.
-------------------	--

Explanation

An attempt was made to create a shared mapping, but no free SCSI LUN slot was found that was available for all of the hosts in the host cluster.

User response

Unmap one or more volumes to free up at least one SCSI LUN slot and resubmit the command.

CMMVC9077E	The host cluster mapping was not created because of conflicting SCSI LUNs. One of the hosts in the host cluster already has a mapping to this volume, however, another host in the host cluster has a mapping to a different volume but with the same SCSI LUN.
-------------------	--

Explanation

An attempt was made to create a shared mapping, but hosts in the host cluster have mappings with the same SCSI LUN but different volumes.

User response

Remap the volume to a compatible SCSI LUN ID before you change to a shared mapping, or remove the private mappings for other hosts to eliminate the conflicts.

CMMVC9078E	A volume listed in the -ignoreseedvolume list does not have a mapping to any of the hosts specified in the -seedfromhost list.
-------------------	---

Explanation

A volume was specified as "non-seeding," but that volume is not mapped to the seeding host.

User response

Retry the command and specify a volume that is mapped to the seeding host.

CMMVC9079E	Cannot delete all the hosts, because at least one of the hosts has mappings. After deleting all the hosts, all of their mappings will be deleted as well. Use -force flag to continue.
-------------------	---

Explanation

An attempt was made to remove multiple hosts from a host cluster while at least one of the hosts was still mapped to a volume.

User response

- Delete the mappings for any hosts that you want to remove from a host cluster.
- Alternatively, use the **-force** flag to automatically delete all the mappings for a host when that host is removed.

Note: Use of the **-force** flag can have unintended consequences.

CMMVC9080E	The host cluster I/O group(s) cannot be removed because at least one volume in the I/O group(s) has received I/O within the defined volume protection period.
-------------------	--

Explanation

An attempt was made to remove an I/O group where global volume protection is enabled and I/O occurred within the specified quiet period.

User response

Make sure that you specified the correct I/O group. If so, make sure that no activity that involves the I/O group takes place during the required quiet period before you retry the command.

CMMVC9081E	Duplicate host IDs were entered.
-------------------	---

Explanation

An attempt was made to add or remove multiple hosts from a host cluster where the same host ID was specified twice.

User response

Correct the host IDs, specifying each ID only once, and retry the command.

CMMVC9082E Too many hosts supplied in the list.

Explanation

A list of hosts that are to be added to a host cluster was provided, but the number of hosts in the list is too large. A host cluster can include a maximum of 128 hosts.

User response

Retry the command with a shorter list of hosts.

CMMVC9083E A new cloud snapshot could not be created because the volume is not ready.

Explanation

A cloud snapshot cannot be created if any of the following conditions apply:

- A cloud snapshot, restore, or delete operation is already in progress on the volume
- An unfixed cloud snapshot error is logged against the volume

A new cloud snapshot can be started only when the volume **backup_status** is **ready**.

User response

Complete the following actions:

1. Fix any outstanding snapshot errors and retry the command.
2. If the error persists, use the management GUI or the **lsvolumebackupprogress** and **lsvolumerestoreprogress** commands to monitor the progress of existing cloud snapshot, delete, and restore operations. Wait for the existing operation to complete, or cancel the operation, and then retry the original command.

CMMVC9084W Volumes that are enabled for cloud snapshots exist without a license for each enclosure.

Explanation

Each enclosure that contains a volume that is enabled for cloud snapshots must have a valid transparent cloud tiering license. At least one enclosure is missing a license.

User response

Obtain a valid transparent cloud tiering license for any enclosures that require one.

CMMVC9085E The command failed because the cloud account is still being initialized.

Explanation

Initialization of the cloud account must complete before the cloud account can be used.

User response

Wait for initialization of the cloud account to complete, then retry the command.

CMMVC9086E A new cloud snapshot could not be created because the cloud account configured for the volume is in import mode.

Explanation

A new cloud snapshot can be created only when the cloud account is in normal mode.

User response

Change the mode of the cloud account or configure the volume to use a different cloud account.

CMMVC9087E A new cloud snapshot cannot be created because the volume is not enabled for cloud snapshots.

Explanation

A new cloud snapshot can be created only when the cloud snapshot function is enabled.

User response

Enable the cloud snapshot function for the volume by using the management GUI or the **chvdisk** command.

CMMVC9088E A new cloud snapshot could not be created because the maximum number of cloud snapshots already exists for the volume.

Explanation

The volume already has the maximum number of cloud snapshots.

User response

Remove any unwanted cloud snapshots for the volume and retry the command. Use the management GUI or the **lsvolumebackupgeneration** and **rmvolumebackupgeneration** commands to list and remove cloud snapshots.

CMMVC9089E	The command failed because no cloud snapshots for the specified volume exist.
-------------------	--

Explanation

An attempt was made to remove cloud snapshots where a valid volume ID was provided, but no cloud snapshots for the specified volume were found.

User response

Use the management GUI or the **lsvolumebackup** command to list the volumes for which cloud snapshots exist in the cloud. Specify one of these volumes when you retry the command.

CMMVC9090E	The command failed because the specified cloud snapshot does not exist.
-------------------	--

Explanation

An attempt was made to remove or restore a cloud snapshot, but the specified snapshot was not found in the cloud.

User response

Use the management GUI or the **lsvolumebackupgeneration** or **lsvolumebackup** command to list the cloud snapshots that exist in the cloud for a particular volume. Specify one of these snapshots when you retry the command.

CMMVC9091E	The command failed because an existing delete operation is in progress for this volume.
-------------------	--

Explanation

Only one delete operation is allowed at a time for a volume that has cloud snapshots. The delete process is asynchronous and runs in the background. While that process is running for one snapshot, you cannot delete another snapshot of the same volume.

User response

Use the management GUI or the **lsvolumebackupprogress** command to list the progress of current delete operations. When no other delete operations are in progress for the volume, retry the command.

CMMVC9092E	The command failed because the specified cloud snapshot is the most recent complete cloud snapshot for the volume.
-------------------	---

Explanation

An attempt was made to delete the most recent cloud snapshot for a volume. The most recent snapshot must remain available for use in restore operations.

User response

Use the management GUI or the **lsvolumebackup** to choose a different cloud snapshot to delete.

CMMVC9093E	The command failed because a restore operation is in progress from this cloud snapshot.
-------------------	--

Explanation

An attempt was made to delete a cloud snapshot while it was being used to restore a volume.

User response

Wait for the restore operation to complete, or cancel the restore operation. Use the management GUI or the **lsvolumerestoreprogress** command to display the progress of current restore operations.

CMMVC9094E	The command failed because a restore operation is in progress from one of the cloud snapshots for this volume.
-------------------	---

Explanation

An attempt was made to delete all cloud snapshots for a volume while one of the cloud snapshots is being used to restore a volume.

User response

Wait for the restore operation to complete, or cancel the restore operation. Use the management GUI or the **lsvolumerestoreprogress** command to list the progress of current restore operations.

CMMVC9095E	The command failed because a volume with the UID specified
-------------------	---

with the **-fromuid** parameter already exists on the local system.

Explanation

The **-fromuid** parameter is used to restore a cloud snapshot that was taken from a different volume.

User response

Do not use the **--fromuid** parameter when the specified volume already exists on the local system.

CMMVC9096E **The command failed because an existing restore operation is in progress on this volume.**

Explanation

An attempt was made to restore a volume that was already being restored.

User response

Wait for the restore operation to complete. If you specified the wrong volume, you can display a list of all volumes for which a restore operation is in progress by using the management GUI or the **lsvolumerestoreprogress** command. Specify a volume for which no restore operations are in progress when you retry the original command.

CMMVC9097E **The command failed because the specified version of the cloud snapshot is not the latest cloud snapshot for the volume. The -deletelatergenerations parameter must be specified if the latest version of the cloud snapshot is not specified.**

Explanation

If cloud snapshots are enabled on the volume, and the cloud snapshot that is being restored is not the most recent cloud snapshot of the volume, then all later cloud snapshots for the volume must be deleted by specifying the **-deletelatergenerations** parameter.

User response

Complete one of the following actions:

- Retry the command with the **-deletelatergenerations** parameter.
- If you are restoring directly to the production volume, disable cloud snapshots on the volume and retry the command. If cloud snapshots are enabled

later, the next cloud snapshot will be a full cloud snapshot.

- If you are committing a restore from a temporary volume, consider converting the temporary volume into an independent volume by using the **-detach** parameter. You can then keep the original volume and volume cloud snapshots unchanged.

CMMVC9098E **The command failed because an existing restore operation is in progress from this volume cloud snapshot.**

Explanation

An attempt was made to restore a volume where the specified cloud snapshot was already in use for a restore operation.

User response

Use the management GUI or the **lsvolumerestoreprogress** command to list the progress of current restore operations.

CMMVC9099E **The command failed because no restore operation is in progress for this volume.**

Explanation

An attempt was made to cancel a restore for a volume for which no restore operation is in progress.

User response

To display a list of all volumes for which a restore operation is in progress, use the management GUI or the **lsvolumerestoreprogress** command. Specify one of these volumes when you retry the original command.

CMMVC9100E **The command failed because there is no uncommitted restore operation for this volume.**

Explanation

An attempt was made to commit or detach a restore for a volume for which no uncommitted restore operation was found.

User response

To display a list of all volumes for which a restore operation is in progress, use the management GUI or the **lsvolumerestoreprogress** command. Specify one of these volumes when you retry the original command.

CMMVC9101E The command failed because the -fromuid parameter was specified and the specified local volume has cloud snapshot enabled.

Explanation

An attempt was made to restore a cloud snapshot from a different volume. However, cloud snapshots are enabled on the specified local volume.

When you use the **-fromuid** parameter, cloud snapshots cannot be enabled on the local volume.

User response

Complete one of the following actions:

- Disable cloud snapshots on the local volume and retry the command.
- Restore to a different local volume.

CMMVC9102E The command failed because the -restoreuid parameter was specified when the existing volume has mappings to hosts.

Explanation

An attempt was made to restore a cloud snapshot from a different volume, where the UID of the local volume was requested to be set to the UID of the volume cloud snapshot. However, the local volume has mappings to a host object.

When you use the **-restoreuid** parameter, the local volume cannot have any volume to host mappings.

User response

Complete one of the following actions:

- Remove the volume to host mappings for the local volume and retry the command.
- Restore to a different local volume.

CMMVC9103E A restore operation could not be started because the volume is not ready.

Explanation

A restore operation cannot be started if any of the following conditions apply:

- A cloud snapshot, restore, or delete operation is already in progress on the volume
- An unfixed cloud snapshot error is logged against the volume

A restore operation can be started only when the volume **restore_status** is **available**.

2100 Spectrum Virtualize for SAN Volume Controller, FlashSystem, and Storwize Family: Command-Line Interface User's Guide

User response

Complete the following actions:

1. Fix any outstanding snapshot errors and retry the command.
2. If the error persists, use the management GUI or the **lsvolumebackupprogress** and **lsvolumerestoreprogress** commands to monitor the progress of existing cloud snapshot, delete, and restore operations. Wait for the existing operation to complete, or cancel the operation, and then retry the original command.

CMMVC9104E A cloud snapshot could not be deleted because the volume is not ready.

Explanation

A cloud snapshot cannot be deleted if any of the following conditions apply:

- A cloud snapshot, restore, or delete operation is already in progress on the volume
- An unfixed cloud snapshot error is logged against the volume

User response

Complete the following actions:

1. Fix any outstanding snapshot errors and retry the command.
2. If the error persists, use the management GUI or the **lsvolumebackupprogress** and **lsvolumerestoreprogress** commands to monitor the progress of existing cloud snapshot, delete, and restore operations. Wait for the existing operation to complete, or cancel the operation, and then retry the original command.

CMMVC9105E The command failed because the local volume is a different size than the specified cloud snapshot.

Explanation

An attempt was made to restore a volume that does not have the same provisioned capacity as the volume cloud snapshot.

User response

Resize the local volume and retry the command, or restore to an alternative local volume.

CMMVC9106E The command failed because the -createtemporaryvolume option can be used only if the volume is enabled for cloud snapshots.

Explanation

An attempt was made to create a temporary volume to hold the restored data, but cloud snapshots are not enabled on the target volume for the restore operation. This usage is not supported.

User response

Complete one of the following actions:

- Run the restore operation directly to the specified volume by omitting the **-createtemporaryvolume** parameter.
- Enable cloud snapshots on the target volume for the restore operation and retry the command.

CMMVC9107E	A temporary volume could not be created for the restore process because there are insufficient free volume IDs or volume copy IDs in the system.
-------------------	---

Explanation

An attempt was made to create a temporary volume to hold the restored data, which required that a new volume be created in the same caching I/O group as the target volume for the restore operation. The new volume was not created because no free volume IDs or volume copy IDs were available in the system.

User response

Determine whether the system includes unwanted volumes or volume copies. If so, remove unwanted volumes or volume copies by using the **rmvolume** or **rmvolume copy** command, and then retry the command.

CMMVC9108E	The volume cannot be resized because the volume is enabled for cloud snapshots.
-------------------	--

Explanation

An attempt was made to change the size of a volume when the cloud snapshot feature was enabled on the volume.

User response

Make sure that you specified the correct volume. If so, disable the cloud snapshot feature on the volume by using the **chvdisk** command and retry the original command.

CMMVC9109E	A temporary volume could not be created for the restore process because there is insufficient free capacity in the storage pool.
-------------------	---

Explanation

An attempt was made to create a temporary volume to hold the restored data, which required that a new volume be created in the same caching I/O group as the target volume for the restore operation. The new volume was not created because no free volume IDs were available in the storage pool.

User response

Determine whether the system includes unwanted local volumes. If so, remove unwanted local volumes by using the **rmvdisk** command, and then retry the command.

CMMVC9110E	The restore operation could not be started because the maximum number of FlashCopy mappings in the system has been reached.
-------------------	--

Explanation

The restore operation requires an internal FlashCopy mapping to be created and the system limit has been reached.

User response

Remove unwanted FlashCopy mappings from the system by using the **rmfcmap** command and retry the **restorevolume** command.

CMMVC9111E	The command failed because the specified volume is part of a Metro Mirror or Global Mirror relationship.
-------------------	---

Explanation

An attempt was made to restore to a volume that is part of a remote copy relationship.

User response

Make sure that you specified the correct volume. If so, remove the remote copy relationship that uses this volume by using the **rmrcrelationship** command and retry the **restorevolume** command.

CMMVC9112E	The command failed because the specified volume is a HyperSwap volume.
-------------------	---

Explanation

An attempt was made to restore to a HyperSwap volume. This operation is not allowed.

User response

Make sure that you specified the correct volume. If so, convert the volume to a basic volume by removing a copy at one site, then retry the command.

CMMVC9113E	Cloud snapshots are already enabled for the specified volume.
-------------------	--

Explanation

An attempt was made to enable cloud snapshots on a volume where cloud snapshots are already enabled.

User response

Make sure that you specified the correct volume. If you want to enable cloud snapshots that use a different cloud account, first disable cloud snapshots for the current account, then retry the command.

CMMVC9114E	Cloud snapshots cannot be disabled because they are not enabled on this volume.
-------------------	--

Explanation

An attempt was made to disable the cloud snapshot function when it was not enabled.

User response

Make sure that you specified the correct volume.

CMMVC9115E	Cloud snapshots cannot be enabled because the maximum number of cloud snapshot-enabled volumes in the system has been reached.
-------------------	---

Explanation

The system limit was reached for the number of volumes that can be enabled for cloud snapshots.

User response

You must disable cloud snapshots for another volume before you can enable cloud snapshots for the current volume.

CMMVC9116E	Cloud snapshots cannot be enabled because the specified cloud account is in import mode.
-------------------	---

Explanation

The cloud account must be in normal mode when you enable cloud snapshots.

User response

Change the account to normal mode and retry the command.

CMMVC9117E	The volume was not deleted because a cloud snapshot operation is in progress.
-------------------	--

Explanation

The volume was not deleted because it would prevent a cloud snapshot operation from completing.

User response

Make sure that you specified the correct volume. If so, wait for the cloud snapshot operation to complete, or cancel the cloud snapshot. Use the management GUI or the **lsvolumebackupprogress** command to monitor the progress of the cloud snapshot, or the **rmvolumebackupgeneration** command to cancel the cloud snapshot. Alternatively, specify the **-cancelbackup** parameter to force-delete the volume, canceling any active cloud snapshot operations on the volume.

CMMVC9118E	The volume was not deleted because a restore operation is in progress and it would allow access to an image mode copy that does not contain consistent data.
-------------------	---

Explanation

The volume was not deleted because an image mode copy might contain inconsistent data.

User response

Make sure that you specified the correct volume. If so, wait for the restore operation to complete, or cancel the restore. Use the management GUI or the **lsvolumerestoreprogress** command to monitor the progress of the restore, or the **restorevolume** command to cancel the restore. Alternatively, specify the **-discardimage** parameter to force-delete the volume, canceling any active restore operation.

CMMVC9119E	The volume copy was not deleted because a restore operation is in progress and it might allow access to an image mode copy that does not contain consistent data.
-------------------	--

Explanation

The volume copy was not deleted because an image mode copy might contain inconsistent data.

User response

Make sure that you specified the correct volume. If so, wait for the restore operation to complete, or cancel the restore. Use the management GUI or the **lsvolumerestoreprogress** command to monitor the progress of the restore operation, or the **restorevolume** command to cancel the restore operation. Alternatively, specify the **-discardimage** parameter to force-delete the volume copy.

CMMVC9120E **The remote copy relationship was not created because the master or auxiliary volume is enabled for cloud snapshots.**

Explanation

A volume where cloud snapshots are enabled cannot be part of a remote copy relationship.

User response

Make sure that you specified the correct volume. If so, disable the cloud snapshot feature by using the **rmcloudaccount** command and retry the original command.

CMMVC9121E **The change volume could not be associated because the volume is enabled for cloud snapshots.**

Explanation

A volume cannot be configured as a change volume for a remote copy relationship if the cloud snapshot feature is enabled on the volume.

User response

Make sure that you specified the correct volume. If so, disable the cloud snapshot feature on the volume by using the **rmcloudaccount** command and retry the original command.

CMMVC9122E **The FlashCopy mapping was not created because the source or target volume is enabled for cloud snapshots.**

Explanation

A volume cannot be the source or target volume in a FlashCopy mapping if the cloud snapshot feature is enabled on the volume.

User response

Make sure that you specified the correct volume. If so, disable the cloud snapshot feature on the volume by

using the **chvdisk** command and retry the original command.

CMMVC9123E **The command failed because a key server type has not been enabled.**

Explanation

An attempt was made to create a key server without enabling a key server type.

User response

Enable a key server type by using the **chkeyserverisklm** command. Then, retry the **mkkeyserver** command.

CMMVC9124E **The command failed because a primary key server already exists.**

Explanation

An attempt was made to create a key server object by using the **mkkeyserver -primary** command where the primary key server already exists. After the primary key server is created, subsequent key server objects cannot be created with the **-primary** flag. The primary key server can be changed later by using the **chkeyserver** command.

User response

Retry the command without specifying the **-primary** flag.

CMMVC9125E **The command failed because the -primary flag must be set when creating the first ISKLM key server.**

Explanation

An attempt was made to create the primary ISKLM key server object without specifying the **-primary** flag. The first key server that you create of the ISKLM type must have the **-primary** flag set. In other words, you must create your primary key server first. Subsequent key server objects cannot be created with the **-primary** flag. The primary ISKLM key server can be changed later by using the **chkeyserver** command.

User response

Specify the **-primary** flag when you retry the command.

CMMVC9126E **The command failed because the -primary flag can only be set for ISKLM key servers.**

Explanation

An attempt was made to create a key server object where the **-primary** flag was specified. The **-primary** flag is valid only for ISKLM key servers, but the ISKLM key server type is not currently enabled.

User response

Retry the command without specifying the **-primary** flag.

CMMVC9127E	The command failed because an SSL certificate is required.
-------------------	---

Explanation

An attempt was made to create a key server object without specifying a self-signed SSL certificate. The parent key server type object does not have a CA certificate configured either. As a result, no SSL certificate would be available on the system for communicating with the key server.

User response

Configure a CA certificate for this key server type or supply a self-signed certificate for the key server with the **-sslcert** parameter.

CMMVC9128E	Cannot enable key server type because it would exceed the permitted number of enabled key server types.
-------------------	--

Explanation

One key server type is typically enabled at a time. Migration between key server types is a special case where a second type can be enabled until the migration is complete. This error means that an attempt was made to enable a third key server type during a migration, which is not permitted.

User response

If you are currently migrating between two key server types, try the command again and this time include the **-disable** parameter to disable the migration target.

CMMVC9129E	The command has failed because an IPv4 address was specified and each node does not have an IPv4 service IP address.
-------------------	---

Explanation

An attempt was made to create the key server object with an IPv4 address, which requires each node in the system to have an IPv4 service IP address set.

User response

Use the **lsservicestatus** command to ensure that each node in the system has an IPv4 service IP address and then retry the command. Alternatively, if each node has an IPv6 service address, specify an IPv6 service IP address when you retry the command.

CMMVC9130E	The command has failed because an IPv6 address was specified and each node does not have an IPv6 service IP address.
-------------------	---

Explanation

An attempt was made to create the key server object with an IPv6 address, which requires each node in the system to have an IPv6 service IP address set.

User response

Use the **lsservicestatus** command to ensure that each node in the system has an IPv6 service IP address and then retry the command. Alternatively, if each node has an IPv4 service address, specify an IPv4 service IP address when you retry the command.

CMMVC9131E	The command failed because the key server reported an error.
-------------------	---

Explanation

An attempt was made to create or test a key server on the system. During both the **mkkeyserver** and **testkeyserver** tasks, the system attempts to validate the key server. During this validation, the key server reported an error. More detailed information about the error might be found in the additional sense data in the event log.

User response

Check the event log for key server errors. Fix any key server errors and run the task again.

CMMVC9132E	This will change the site of at least one host in the host cluster that already has a site defined. Use -force flag to continue.
-------------------	---

Explanation

An attempt was made to change the site of the host cluster, which would change the site of at least one host in the host cluster.

User response

Make sure you specified the correct information in the command. If so, you can use the **-force** flag to forcibly change the site of one or more hosts in the

host cluster. Using the **-force** flag can have unexpected results.

CMMVC9134E The command failed because the key server is not supported.

Explanation

An attempt was made to create or test a key server on the system. During both the **mkkeyserver** and **testkeyserver** tasks, the system attempts to validate the key server. During this validation, the key server reported unsupported vendor information. More detailed information about the server might be found in the additional sense data in the event log.

User response

Check the event log for key server errors. Fix any key server errors and run the task again.

CMMVC9135E The command failed because there was a problem establishing a connection to the key server.

Explanation

An attempt was made to create or test a key server on the system. During both the **mkkeyserver** and **testkeyserver** tasks, the system attempts to validate the key server. An error occurred in establishing a connection to the key server by using the supplied IP address, IP port, and SSL certificate for the key server. This error might be caused by a network problem, incorrect IP address or port details, or a problem with the SSL certificate. More detailed information about the error might be found in the additional sense data in the event log.

User response

Confirm that the correct IP address, IP port, and SSL certificate were supplied for the key server. Confirm that each node in the system has access to the key server. Confirm that the key server is fully operational and run the task again.

CMMVC9136E The command failed because the key server's response was not understood.

Explanation

An attempt was made to create or test a key server on the system. During both the **mkkeyserver** and **testkeyserver** tasks, the system attempts to validate the key server. The system was unable to process the response from the key server.

User response

Fix any key server errors and run the task again.

CMMVC9137E The command failed because no primary key server exists.

Explanation

An attempt was made to create new key server master keys without a primary key server object. The key server object that is marked as primary is responsible for creating new keys. A primary key server object must exist before key server master keys can be created.

User response

Use the **mkkeyserver** command to designate one key server as the primary key server and run the **chencryption** command again.

CMMVC9138E The command failed because no key servers exist.

Explanation

An attempt was made to create new key server master keys when no key server was known to the system. At least one key server object must exist before key server master keys can be created.

User response

Use the **mkkeyserver** command to create a key server object and run the **chencryption** command again.

CMMVC9139E The command failed because not all key servers are online.

Explanation

An attempt was made to create new key server master keys when the status of a key server object shows that it is not online. All key server objects must be online before key server master keys can be created.

User response

Check the status of all key servers and fix any issues. Run the command again when the status of all key servers is online.

CMMVC9140E The key server could not be deleted because it is the only key server of the enabled key server type.

Explanation

An attempt was made to delete the last remaining key server object for a key server type with a status of **enabled_active**. Deleting this key server would result in loss of access to encryption keys and might cause encrypted objects to go offline.

User response

Use the **chencryption** command to disable key server encryption.

CMMVC9141E The validate command is not valid for key servers. Use the testkeyserver command to validate a key server.

Explanation

An attempt was made to use the **chencryption -keyserver validate** command for key servers, which is not permitted. Only a single key server can be tested at once.

User response

Use the **testkeyserver** command to test individual key server objects.

CMMVC9142E The command failed because another encryption function is already enabled.

Explanation

An attempt was made to enable a second encryption function when another function is already enabled on the system. For example, key server encryption might have been requested when USB encryption was already enabled.

User response

To enable the new encryption function, first use the **chencryption** command to disable the function that is currently enabled.

CMMVC9143E The command failed because the key server reported that the primary has been misconfigured on the system.

Explanation

An SKLM key server reported a server type that conflicted with the value defined on the system. The key server reported it is not the primary, but the server is defined to be the primary on the system.

User response

Make sure that the correct key server is designated as primary. For more information, see the documentation for error code 1785.

CMMVC9144E The command failed because the system cannot retrieve the current key from the primary key server.

Explanation

An attempt was made to complete one of the following actions on a system that is configured to use key server encryption:

- Disable the USB encryption function that is enabled along with key server encryption.
- Prepare a USB encryption key for the first time.

To safely allow USB encryption to be disabled, or to allow USB keys to be prepared for the first time, the system checks that it has access to the current encryption key on the primary key server. This error message is displayed because the system was not able to fetch the key. Possible reasons for the failure include the following situations:

- A network issue prevented connection with the key server.
- The encryption key does not exist on the key server.
- No primary key server is configured on the system.

User response

Fix any key server problems in the event log to bring the primary key server online, then retry the command. If the problem persists, verify that the current key exists on the primary key server.

CMMVC9145E Unable to perform LBA lookup due to unreadable metadata.

Explanation

A reverse lookup failed due to media errors.

User response

Use your host application to validate the data on the volume. After you have located the hard disk errors, restore the missing data from backup.

If the volume is mirrored, and the affected volume is one of the copies, you can use the **repairvdiskcopy** command with the **-validate** flag to compare the faulty copy to the good one. Use the **-resync** option to restore the data from the good copy to the faulty one.

CMMVC9146E **Cannot add or remove support center objects when support assistance is enabled.**

Explanation

Support center configurations cannot be modified while secure remote access is enabled.

User response

Disable support assistance by using the **chstra -disable** command and try the original command again.

CMMVC9148E **The command has failed because the default support center cannot be deleted.**

Explanation

Some support center objects are added when you first install the software or update to the current version. These objects cannot be deleted.

User response

Specify a non-default support center object for deletion.

CMMVC9157E **The command has failed because the specified secondary expansion module is offline.**

Explanation

The specified secondary expansion module is offline.

User response

This error starts a directed maintenance procedure (DMP) that gives instructions for reseating or replacing the module. If the DMP is not displayed, contact IBM Support.

CMMVC9158E **The command has failed because the specified display panel is offline.**

Explanation

The specified display panel is offline.

User response

This error starts a directed maintenance procedure (DMP) that gives instructions for replacing the display panel. If the DMP is not displayed, contact your support representative.

CMMVC9159E **Host is invalid or does not exist**

Explanation

The ID or name of the host that is to be throttled was not valid or was not found.

User response

Use the **lshost** command to create a list of valid hosts. Retry the command with a valid host.

CMMVC9160E **Throttle is already associated with this host.**

Explanation

The host that was specified in the **mkthrottle** command already has an associated throttle.

User response

Make sure that you specified the correct host. If necessary, use the **lshost** command to create a list of valid hosts and retry the command with a valid host. If you want to change the throttle parameters for this host, use the **chthrottle** command.

CMMVC9161E **Host already has an associated host cluster throttle.**

Explanation

A host cannot have a throttle if its parent host cluster defines a host cluster throttle.

User response

Make sure that you specified the correct host. If necessary, use the **lshost** command to create a list of valid hosts and retry the command with a valid host. You can tune the system by changing the host cluster throttle to accommodate the requirements of the member hosts by using the **chthrottle** command.

CMMVC9162E **Hostcluster is invalid or does not exist.**

Explanation

The ID or name of the host cluster that is to be throttled was not valid or was not found.

User response

Use the **lshostcluster** command to create a list of valid host clusters, and then retry the command with a valid host cluster.

CMMVC9163E **Throttle is already associated with this hostcluster.**

Explanation

The host cluster that was specified in the **mkthrottle** command already has an associated throttle.

User response

Make sure that you specified the correct host cluster. If necessary, use the **lshostcluster** command to create a list of valid host clusters and retry the command with a valid host cluster. If you want to change the throttle parameters for this host cluster, use the **chthrottle** command.

CMMVC9164E Host cluster has a member host which has a throttle defined for it.

Explanation

An attempt was made to define a throttle for a host cluster where throttles are already defined for one or more member hosts. This action is not permitted.

User response

Make sure that you specified the correct host cluster. If so, use the **lsthrottle** command to review the hosts that have throttles. If the information shown is correct and you do not need to define a throttle for the host cluster, no further action is required. If you want to define a throttle for the host cluster, you must remove the individual host throttles by using the **rmthrottle** command. When no throttles are defined for any of the member hosts, retry the command.

CMMVC9165E Mdiskgroup is invalid or does not exist.

Explanation

The ID or name of the storage pool that is to be throttled was not valid or was not found.

User response

Use the **lsmdiskgrp** command to create a list of valid storage pools. Retry the command with a valid storage pool.

CMMVC9166E Throttle is already associated with this mdiskgroup.

Explanation

The storage pool that was specified in the **mkthrottle** command already has an associated throttle.

User response

Make sure that you specified the correct storage pool. If necessary, use the **lsmdiskgrp** command to create a list of valid storage pools and retry the command with a valid storage pool. If you want to change the throttle parameters for this storage pool, use the **chthrottle** command.

CMMVC9167E Host and hostcluster already have associated throttles.

Explanation

An attempt was made to add a host to a host cluster when throttles were already defined for both the host and the host cluster. Throttles can be defined for the host or for the host cluster, but not for both.

User response

Use the **rmthrottle** command to remove either the host throttle or the host cluster throttle, then retry the **addhostclustermember** command.

CMMVC9168E Seeding host has a throttle associated with it.

Explanation

An attempt was made to create a host cluster when a throttle was defined for one or more of the seeding hosts.

User response

Use the **rmthrottle** command to remove throttles from any seeding hosts, then retry the **mkhostcluster** command.

CMMVC9173E The pool specified is a data reduction pool. Thin provisioned or compressed volume copies created from a data reduction pool must use -autoexpand.

Explanation

When you create a volume copy from a data reduction pool, you must enable the autoexpand capability. The command fails if you try to create a thin-provisioned or compressed volume copy from a data reduction pool and do not specify the **-autoexpand** parameter.

User response

Use the **-autoexpand** parameter when you create a thin-provisioned or compressed volume copy from a data reduction pool.

CMMVC9175E **The pool specified is a data reduction pool. Volumes or volume copies which are thin provisioned or compressed and created from a data reduction pool can not be striped specifying an mdisk, sequential or image mode.**

Explanation

When you create a thin-provisioned or compressed volume or volume copy from a data reduction pool, do not specify striped with **mdisk**, **sequential**, or **image** mode.

User response

Retry the command with valid options. You can use striped mode if you do not specify an MDisk.

CMMVC9176E **The pool specified is a data reduction pool. For volumes or volume copies which are thin provisioned or compressed and created from a data reduction pool, the volume cannot have a cache mode of none or readonly.**

Explanation

A thin-provisioned or compressed volume or volume copy that you create from a data reduction pool must have a cache mode of **readwrite**.

User response

Change the cache mode on the volume to **readwrite** and retry the command.

CMMVC9177E **The pool specified is a data reduction pool. Thin provisioned or compressed volume copies created from a data reduction pool can not use -noautoexpand.**

Explanation

A thin-provisioned or compressed volume copy created from a data reduction pool must have the autoexpand option enabled.

User response

Retry the command without the **-noautoexpand** parameter.

CMMVC9179E **The command failed as the resource required for a data reduction pool could not be allocated.**

Explanation

Insufficient system resources are available to create a data reduction pool.

User response

Delete enough volume copies, volumes, or pools to free the needed system resources, then retry the command.

CMMVC9180E **The data reduction pool can not be created as the maximum number of data reduction pools already exists.**

Explanation

A maximum of four data reduction pools can be created per system.

User response

Use the **rmmdiskgrp** command to delete an existing data reduction pool and then retry the original command.

CMMVC9181E **Data reduction can only be set to on for a parent pool.**

Explanation

A child pool cannot be designated as a data reduction pool.

User response

Use the **chmdiskgrp** command to change the parent pool to use data reduction and then use the **chmdiskgrp** command to change the child pool to an inherited data reduction pool.

CMMVC9184E **The volume specified is a thin or compressed volume in a data reduction pool. Autoexpand must be on and can not be changed.**

Explanation

Thin-provisioned or compressed volumes cannot have an autoexpand option that is turned off.

User response

Make sure the **-autoexpand** parameter is set to on and then retry the command.

CMMVC9185E **The volume or volume copy specified is a thin or compressed volume in a data reduction pool**

and the action requested is not supported on volumes of this type.

Explanation

The command cannot be run if either copy is a thin-provisioned or compressed volume in a data reduction pool.

User response

Retry the command, specifying volumes that meet at least one of the following requirements:

- The volumes are fully allocated.
- The volumes are in a regular pool.

CMMVC9186E **The pool specified is a data reduction pool. It is not possible to migrate thin or compressed volumes to a data reduction pool.**

Explanation

You cannot migrate thin-provisioned or compressed volumes to a data reduction pool by using the **migratevdisk** command.

User response

Complete the following steps to migrate a thin-provisioned or compressed volume to a data reduction pool:

1. Create a copy of the thin-provisioned or compressed volume in the data reduction pool by using the **addvdiskcopy** command.
2. Delete the original version of the volume copy by using the **rmvdiskcopy** command.

CMMVC9190E **The pool specified is a data reduction pool, creating thin or compressed volumes from this type of pool must have autoexpand on.**

Explanation

You must enable the autoexpand option for all thin-provisioned or compressed volumes in data reduction pools.

User response

For the **mkvdisk** command, make sure that the **-autoexpand** parameter is set to on.

For the **mkvolume** command, make sure that the **-noautoexpand** parameter is *not* included.

Retry the command.

CMMVC9191E **The command failed because the volume is enabled for cloud snapshots.**

Explanation

An attempt was made to migrate a volume between storage pools or to add a copy of a volume to different storage pool when the cloud snapshot feature was enabled on the volume. These actions are not permitted.

User response

Make sure that you specified the correct volume. If so, disable the cloud snapshot feature by using the **chvdisk** command and retry the original command.

CMMVC9193E **The command failed because the system requested for import does not have data in the account.**

Explanation

An attempt was made to configure a cloud account to import data from another system, but the other system does not have data in its account.

User response

Check the list of systems with data in the account by using the **lsccloudaccountimportcandidate** command and retry the original command.

CMMVC9194E **The command failed because at least one volume is using the account.**

Explanation

An attempt was made to change the mode of a cloud account when at least one of the volumes in the system is configured to use the account. For example, a volume might be configured to use cloud snapshots. The account mode cannot be changed until these volumes are reconfigured to not use the account.

User response

Reconfigure the volumes that are using the account and retry the command.

CMMVC9195E **The account cannot be deleted because it is being used by volumes.**

Explanation

An attempt was made to delete a cloud account, but volumes on the system are configured to use that

account. For example, a volume might be configured to use the cloud snapshot function.

User response

Make sure that you specified the correct account. If so, verify that you want to disconnect the volumes that use the account. If so, disconnect the volumes and retry the command.

CMMVC9196E All available quorum disks are dependent on the sem that you have specified.

Explanation

All quorum disks depend on the specified secondary expander module (SEM). You must configure the system so that at least one of the drives that are allocated to hold quorum remains online when the canister goes offline.

User response

Assign one or more of the drives in the control enclosure as a quorum drive by using the **chquorum** command. After you configure the quorum drives, test for dependencies by using the **lsdependentvdisks** command with the **-sem** option.

CMMVC9197E Cloud snapshot and restore operations are not allowed because of a generation delete abandon. Use **rmvolumebackupgeneration** to retry the delete operation.

Explanation

A previous generation delete operation was abandoned. You must complete this operation before further snapshot or restore operations can be run.

User response

Rerun the abandoned generation delete operation for the volume. When the operation is complete, new snapshot and restore operations are possible. Use the management GUI or the **lsvolumebackupgeneration** and **rmvolumebackupgeneration** commands to list and remove snapshot generations.

CMMVC9198E A previous **rmvolumebackupgeneration -all** command was abandoned. Use **rmvolumebackupgeneration -all** to retry the delete operation.

Explanation

A previous generation delete operation that used the **-all** option was abandoned. The operation must complete before further snapshots or restores are allowed.

User response

Rerun the abandoned generation delete operation for the volume and include the **-all** option. When the operation is complete, new snapshot and restore operations are possible. Use the management GUI or the **rmvolumebackupgeneration -all** command to remove all snapshot generations for a volume.

CMMVC9199E A previous **rmvolumebackupgeneration** or **cloud restore with -deletelatergenerations** command was abandoned. Use **rmvolumebackupgeneration** specifying the lowest deleting generation to retry the delete operation.

Explanation

One of the following operations was abandoned:

- A generation restore operation with the **-deletelatergenerations** option
- A **rmvolumebackupgeneration** operation with the **-generation** option

The operation must complete before further snapshots or restores are allowed.

User response

Run the **lsvolumebackupgeneration** command and look for one or more generations that are labeled **deleting**. Run the **rmvolumebackupgeneration** operation and specify those generations. When the operation is complete, new snapshot and restore operations are possible.

CMMVC9201E Task failed because volume is mirrored and has at least one copy that is fully allocated and is part of a Metro Mirror or Global Mirror relationship.

Explanation

Volumes that are part of a Metro Mirror or Global Mirror relationship cannot be expanded or shrunk if they are mirrored with at least one copy that is fully allocated.

User response

Delete either copy of the mirrored volume, leaving a fully allocated or thin-provisioned copy that is not mirrored. Then, retry the task.

CMMVC9202E The task failed because the volume is part of a Metro Mirror or Global Mirror relationship to a system which is running software which does not support resize of volumes in a relationship.

Explanation

You can change the size of the volumes that are part of Metro Mirror or Global Mirror relationships only if both systems involved in that relationship are running software that supports the resizing function.

User response

Either upgrade the remote system or remove the Metro Mirror or Global Mirror relationship, then retry the command.

CMMVC9203E The expandvdiskspace task failed because there is not enough memory available for this feature.

Explanation

The volume is part of Metro Mirror or Global Mirror relationship and requires more memory to accommodate the change recording map.

User response

Increase the memory space available for Remote Copy in the caching I/O group of the volume you want to expand, then retry the task.

CMMVC9204E The task failed because the volume is part of a relationship that is configured to operate in Global Mirror in cycling mode.

Explanation

An attempt was made to change the size of a volume that is part of a Global Mirror relationship while that relationship is configured to operate in multiple cycling mode. This change is not permitted.

User response

Complete one of the following procedures:

- Delete the Global Mirror relationship.
- Remove the relationship from any consistency group, convert the single relationship to Global

Mirror non-cycling mode, start the relationship, and wait until the relationship achieves a `consistent_synchronized` state.

Retry the volume size change.

CMMVC9205E The task failed because the volume is part of a HyperSwap relationship.

Explanation

Volumes cannot be resized if they are part of a HyperSwap relationship.

User response

Make sure that you specified the correct volume. If so, convert the volume to a basic volume by removing a copy at one site, then retry the command.

CMMVC9206E The task failed because the volume is part of a relationship that is not consistent_synchronized.

Explanation

An attempt was made to resize a volume that is part of a remote copy relationship that is not synchronized. A volume that is part of a Metro Mirror or Global Mirror relationship can be resized only when the relationship is synchronized.

User response

Start the relationship and wait for it to synchronize, and then retry the resize command.

CMMVC9207E The task failed because the volume being expanded is a primary in a Metro Mirror or Global Mirror relationship and would make the primary volume size different than the secondary volume size.

Explanation

The volume that is being expanded is a primary in a Metro Mirror or Global Mirror relationship, and the request to expand is making the volume either larger or smaller than the associated secondary. Volumes in relationships can be expanded by first expanding the secondary by the required amount, and then expanding the primary volume to the same size.

User response

Make sure that the secondary is expanded first, and then adjust the requested size so that the primary

volume becomes the same size as the associated secondary volume.

CMMVC9208E **The task failed because the volume being expanded is a secondary in a Metro Mirror or Global Mirror relationship and has already been expanded so is larger than the associated primary volume.**

Explanation

An attempt was made to expand a secondary volume that was already larger than its associated primary. You cannot expand the secondary volume unless it is the same size as the primary volume.

User response

Either expand the primary volume to the same size as the secondary, or shrink the secondary volume to the same size as the primary. After both volumes are the same size, you can retry the expansion of the secondary volume.

CMMVC9209E **The task failed because the volume being shrunk is a secondary in a Metro Mirror or Global Mirror relationship and would make the secondary volume size different than the associated primary volume.**

Explanation

The volume that is being shrunk is a secondary in a Metro Mirror or Global Mirror relationship, and the request to shrink would make the volume either larger or smaller than the associated primary volume. Volumes in relationships can be shrunk by first shrinking the primary by the required amount, and then shrinking the secondary volume to the same size.

User response

If you want to shrink the secondary volume, the secondary volume must be larger than the primary volume, and you can shrink it to the size of the primary volume only. When both volumes are the same size, you can shrink the primary volume first, then shrink the secondary volume to the same size.

CMMVC9210E **The task failed because the volume being shrunk is a primary in a Metro Mirror or Global Mirror relationship and has already been shrunk so is already smaller than the associated secondary volume.**

Explanation

The volume that is being shrunk is a primary volume that is already smaller than the associated secondary. Volumes in relationships can be shrunk by first shrinking the primary by the required amount, and then shrinking the secondary volume to the same size.

User response

Either shrink the secondary volume to be the same size as the primary volume, or expand the primary volume to be same size as the secondary volume. When both volumes are the same size, you can retry shrinking the primary volume.

CMMVC9211E **Cannot perform task because primary is different size to the secondary.**

Explanation

The specified command can be completed only on a relationship where the primary and secondary volumes are the same size.

User response

Make sure that you specified the correct relationship. If so, either expand the primary to the same size as the secondary, or shrink the secondary to the same size as the primary. You can then retry the command.

CMMVC9212E **Cannot perform task because one or more of the primaries is a different size to the corresponding secondary**

Explanation

The specified command can be completed only on a consistency group where all of the relationships consist of primary and secondary volumes that are the same size.

User response

Ensure that all primary volumes are the same size as their corresponding secondary volumes, then retry the command.

CMMVC9215E **The action failed as the tier cannot be changed for MDisks from this controller.**

Explanation

The tier is fixed for MDisks from this controller.

User response

Make sure that you specified the correct MDisk. If not, specify an MDisk from a controller that allows the tier to be changed.

CMMVC9218E **The action failed because remote support is either in connected or active state.**

Explanation

An attempt was made to test remote support assistance when it was in a connected or active state.

User response

Test only when remote support assistance is in a disconnected, connecting, or failure state.

CMMVC9219E **The command failed because the remote support feature has already been enabled.**

Explanation

The **chstra -remotesupport enable** command was entered when remote support assistance was already enabled.

User response

If all you wanted was to enable remote support assistance, no further action is required.

If you ran the **chstra** command to modify the **-idletimeout** parameter, complete the following steps:

1. Disable remote support by running the **chstra -remotesupport disable** command.
2. Enable remote support with an idle timeout, as in the following example:

```
chstra -remotesupport enable -idletimeout 60
```

This example sets the idle timeout to 60 minutes.

If your support representative advised you to add a new support center, or if you want to configure a proxy server, complete the following steps:

1. Disable support assistance by using the **chstra -disable** command.
2. Configure the new support center or proxy server by using the **mksystemsupportcenter** command.
3. Enable local and remote support assistance as required by using the **chstra -enable** and **chstra -remotesupport enable** commands.

CMMVC9220E **The command failed because the name of the support center started with the prefix associated with default support centers.**

Explanation

An attempt was made to create a support center whose name began with "default_support_center". This prefix is reserved for use by default support centers.

User response

Try the command again and use a name for the support center that does not begin with "default_support_center".

CMMVC9224E **The command failed because the specified node is not a part of the site or I/O group specified, or both.**

Explanation

An attempt was made to change the authentication information for a node that is not a member of the specified site or I/O group.

User response

Complete one of the following actions:

- Retry the command and specify a node that is a member of the specified site or I/O group.
- Use the management GUI or the **addnode** or **chnode** command to add the node to the appropriate site and I/O group, then retry the **chscsistorageport** command.

Note: The **site_id** or **site_name** parameters can be specified for stretched or HyperSwap topologies only.

CMMVC9225E **The command failed because the maximum limit for the initiator node-specific authentication credentials was exceeded.**

Explanation

When you use the initiator node-specific credentials mode, a maximum of 32 characters is allowed for the user name and 32 characters for the chapsecret. This mode is triggered by the **-node** parameter.

User response

Retry the command and specify a user name and chapsecret that each have 32 or fewer characters.

CMMVC9226E The command failed because the specified iSCSI storage port is configured for single username/password credentials across all nodes. Per SVC node credentials cannot be specified.

Explanation

An attempt was made to change the mode of authentication from single credentials system wide to per-node credentials. This iSCSI storage port is configured to use a single user name and password across all nodes.

User response

Retry the command and omit the **-node** parameter.

CMMVC9227E The command failed because the specified iSCSI session does not exist.

Explanation

An attempt was made to change the authentication for an iSCSI session that does not exist.

User response

Retry the command and specify a valid iSCSI session.

CMMVC9228E The command failed because some parameters are missing or invalid parameters were entered.

Explanation

The command contained one or more invalid parameters, or failed to include one or more required parameters, or both.

User response

Refer to the product documentation for the command syntax and retry the command with the correct parameters.

CMMVC9230E The command failed because the system cannot retrieve the current key from a USB flash drive.

Explanation

An attempt was made to complete one of the following actions:

- Disable the key server encryption function while the system is configured to also use USB encryption.
- Prepare a new key server key when key server encryption is being enabled for the first time.

To safely allow key server encryption to be disabled, or to allow key server keys to be prepared for the first time, the system checks that it has access to the current encryption key on at least one of the USB flash drives. This error message is displayed because the system was not able to read the key. Possible reasons for the failure include the following situations:

- The USB flash drive that is installed is defective.
- The USB flash drive belongs to a different system.

User response

Verify that at least one working USB flash drive that contains the correct key for the system is installed in the system, then retry the command.

CMMVC9231E The command failed because a USB re-key operation is in progress.

Explanation

USB encryption is enabled on the system and is currently in the prepared state. An action was attempted that is not permitted in the current state.

User response

Complete the re-key operation by entering one of the following commands:

- `chencryption -usb newkey -key commit`
- `chencryption -usb newkey -key cancel`

Once the re-key operation is complete, retry the original command.

CMMVC9232E The command failed because a key server re-key operation is in progress.

Explanation

Key server encryption is enabled on the system and is currently in the prepared state. An action was attempted that is not permitted in the current state.

User response

Complete the re-key operation by entering one of the following commands:

- `chencryption -keyserver newkey -key commit`
- `chencryption -keyserver newkey -key cancel`

Once the re-key operation is complete, retry the original command.

CMMVC9233E The command failed because a USB re-key operation is required.

Explanation

USB encryption is enabled on the system. An action was attempted that is not permitted until a new USB key has been created.

User response

Create a new USB key for the system by completing the instructions in the topic "Rekeying an encryption-enabled system using a USB flash drive."

CMMVC9234E The command failed because the cloud account is in import mode.

Explanation

An attempt was made to enable or disable a key provider when the cloud account was in import mode. In import mode, the account is read-only and no changes can be made.

User response

Use the change cloud account command for the appropriate provider (such as **chcloudaccountswift**) to change the account mode to **normal**, then retry the original command.

CMMVC9235E The pool specified is a data reduction pool. Volumes or volume copies which are thin provisioned and created from a data reduction pool can not use the -grainsize parameter.

Explanation

You cannot create thin-provisioned volumes or volume copies that use the **-grainsize** parameter. This type of volume or volume copy is created with a mandatory grain size of 8 KB.

User response

Retry the command without the **-grainsize** parameter.

CMMVC9236E The pool specified is a data reduction pool. Volumes or volume copies which are thin provisioned and created from a data reduction pool can not use the -warning parameter.

Explanation

This type of volume or volume copy is created without a warning threshold.

User response

Retry the command without the **-warning** parameter.

CMMVC9237E The volume specified is a thin or compressed volume in a data reduction pool. Cache can not be set to none or readonly.

Explanation

You must enable the cache for thin-provisioned or compressed volumes in a data reduction pool.

User response

Retry the command with a value for the **-cache** parameter other than none or readonly.

CMMVC9238E The volume specified is a thin volume in a data reduction pool. The -warning parameter can not be used.

Explanation

An attempt was made to use the **-warning** parameter of the **chvdisk** command to set a warning threshold for a thin-provisioned volume in a data reduction pool. This action is not permitted. However, you can set a warning threshold at the pool level.

User response

To set a warning threshold at the pool level, use the **chmdiskgrp -warning** command.

CMMVC9240E The action requested is not supported on volumes or volume copies in data reduction pools.

Explanation

You cannot run this command on volumes that are in data reduction pools.

User response

Retry this command and specify a regular pool.

CMMVC9241E The action cannot be completed because the Quorum device is unavailable.

Explanation:

An issue exists in communicating with the Quorum device.

User response:

View the event log and resolve any outstanding issues with the Quorum device.

CMMVC9242E **The volume or volume copy specified is a thin or compressed volume in a data reduction pool. Thin provisioned or compressed volume copies created from a data reduction pool can not use the -rsize parameter.**

Explanation

You cannot specify an **-rsize** parameter for thin-provisioned or compressed volume copies that are created in a data reduction pool. Data reduction pools automatically manage the physical capacity that is used across the volumes in the pool, so you cannot shrink or expand the **-rsize** for this type of volume copy.

User response

Retry the command without the **-rsize** parameter.

CMMVC9243E **Node VPD is unavailable for inactive spare nodes. Use `sainfo lsservicenodes` instead.**

Explanation

The **lsnodevpd** command does not display the vital product data for inactive spare nodes. For most applications, you can use the **sainfo lsservicenodes** command instead.

User response

Use the **sainfo lsservicenodes** command to display vital product data for the node.

CMMVC9245E **The pool specified is a data reduction pool and the IO group selected already contains compressed volumes within a regular pool. An IO group using software compression can not contain compressed volumes from regular and data reduction pools at the same time.**

Explanation

An attempt was made to add a compressed volume from a data reduction pool to an I/O group that already contains at least one compressed volume from a regular pool. I/O groups that use software compression can contain compressed volumes from data reduction pools or regular pools, but not both.

User response

Retry the command and specify a different I/O group or a volume from a regular pool.

CMMVC9246E **The pool specified is a regular pool and the IO group selected already contains compressed volumes within a data reduction pool. An IO group using software compression can not contain compressed volumes from regular and data reduction pools at the same time.**

Explanation

An attempt was made to add a compressed volume from a regular pool to an I/O group that already contains at least one compressed volume from a data reduction pool. I/O groups that use software compression can contain compressed volumes from data reduction pools or regular pools, but not both.

User response

Retry the command and specify a different I/O group or a volume from a data reduction pool.

CMMVC9247E **The pool specified is a data reduction pool. Thin or compressed volumes or volume copies in data reduction pools cannot have the `easytier` status set or changed.**

Explanation

You cannot set the `easytier` mode on a volume or volume copy basis for thin-provisioned or compressed volumes in a data reduction pool. The `easytier` mode is an attribute of the pool and must be set or changed at the pool level.

User response

Use the **mkmdiskgrp** command to set or change the value for the **-easytier** parameter at the pool level.

CMMVC9248E **The volume or volume copy specified is a thin or compressed volume in a data reduction pool. The `easytier` status cannot be changed.**

Explanation

You cannot specify the `easytier` mode of a volume or volume copy that you create from a data reduction pool.

User response

Complete one or both of the following actions:

- Retry the command and omit the **-easytier** parameter.
- Use the **mkmdiskgrp** command to set the value for the **-easytier** parameter at the pool level.

CMMVC9249E **Data reduction pools can not have child pools.**

Explanation

An attempt was made to create a child pool within a data reduction pool.

User response

If you need child pools, you must create them within a regular pool.

CMMVC9250E **The pool specified is a data reduction pool. Thin provisioned or compressed volume copies created from a data reduction pool can not use the -buffer size parameter.**

Explanation

You cannot use the **-buffer size** parameter when you create thin-provisioned or compressed volume copies from a data reduction pool.

User response

Complete one of the following actions:

- Retry the command without the **-buffer size** parameter.
- Retry the command and specify a pool that is not a data reduction pool.

CMMVC9251E **The command failed because the -deletelater generations parameter was specified and the specified local volume has cloud snapshot not enabled.**

Explanation

An attempt was made to restore a cloud snapshot. However, cloud snapshots are not enabled on the specified local volume. When you use the **-deletelater generations** parameter, cloud snapshots must be enabled on the local volume.

User response

Complete one of the following actions:

- Restore the volume without using the **-deletelater generations** parameter.
- Enable cloud snapshots on the local volume by using the **chvdisk** command and then retry the original command.

CMMVC9252E **The command failed because the I/O group contains compressed volumes. The new hardware configuration does not support compressed volumes.**

Explanation

An attempt was made to submit a hardware configuration that does not support compressed volumes, where the I/O group that this node belongs to contains compressed volumes.

User response

Complete one of the following actions:

- Submit a hardware configuration that supports compressed volumes.
- Use the **rmvdisk** command to remove all compressed volumes from the I/O group, and then retry the command.

CMMVC9253E **An IO group using software compression can not contain compressed volumes from regular and data reduction pools at the same time.**

Explanation

The I/O group that was selected supports software compression only. You cannot create a compressed volume that has copies in both a regular pool and a data reduction pool.

User response

Complete one of the following actions:

- Retry the command and select a different I/O group.
- Create the compressed volume with both copies in regular pools or both copies in data reduction pools. Then retry the command.

CMMVC9254E **The command failed because the maximum number of spare nodes have already been assigned to this cluster.**

Explanation

The system already has the maximum number of assigned spare nodes, and additional spares cannot be added.

User response

Use the **rmnode** command to remove an existing spare, then add the new node

CMMVC9256E	The specified node is not an active spare node.
-------------------	--

Explanation

The **swapnode** command was not completed because the specified node is not a spare node.

User response

Retry the command and specify a valid spare node.

CMMVC9257E	The command failed because -deactivatespare was not specified.
-------------------	---

Explanation

An attempt was made to remove a node when a spare node was active in its place. You must deactivate the spare node before the specified node can be removed. The **-deactivatespare** parameter performs the required deactivation as part of the command.

User response

Retry the command and include the **-deactivatespare** parameter.

CMMVC9258E	The command failed because -deactivatespare was specified.
-------------------	---

Explanation

The **-deactivatespare** parameter was used to indicate that a spare node was currently taking the place of the node to be deleted. No spare is actually being used in place of the designated node.

User response

Retry the command and omit the **-deactivatespare** parameter.

CMMVC9259E	The upgrade is currently not paused
-------------------	--

Explanation

An attempt was made to continue a software update (**svctask applysoftware -continue**) when the update was not paused.

You can continue a software update when the **lsupdate** command shows one of the following statuses:

- **system_updating_pausing**
- **system_restoring_pausing**

User response

The most likely scenario is that the continue command was run by mistake. No user response is necessary in this case; the update continues automatically unless you see one of the "pausing" messages in **lsupdate**.

CMMVC9260E	The command failed because the specified node has been replaced by a spare.
-------------------	--

Explanation

The specified node was replaced by a spare, so you cannot currently complete the command. You must restore the original node first.

User response

Restore the original node by entering the **swapnode -failback** command, then retry the original command.

CMMVC9261E	The command failed because the specified node does not have a status of candidate.
-------------------	---

Explanation

The node does not have the required status of "candidate" in the display from the **sainfo lsservicenodes** command.

User response

If the specified node has a status of "service" in **sainfo lsservicenodes** and a node error of 690, run the **satask stopservice** command to exit service mode, then retry the original command.

If your situation does not match these conditions, or if the **stopservice** command is unsuccessful, contact your support representative.

CMMVC9262E	The pool specified is a data reduction pool. The action requested is not supported with pools of this type.
-------------------	--

Explanation

You cannot run this command on a data reduction pool.

User response

Retry the command and specify a regular pool.

CMMVC9264E The task failed because unable to format the newly expanded area in the original volume's last grain

Explanation

An I/O operation related to formatting the last grain of the original volume failed. The expansion process cannot continue. This error can occur when the volume is offline, or when I/O operations are delayed.

User response

Ensure that the volume is online and that I/O operations are not delayed. Try the command again.

CMMVC9265E The volume specified has a thin or compressed volume copy in a data reduction pool. Thin provisioned or compressed volumes created from a data reduction pool can not use -size parameter to reduce the size of the volume.

Explanation

You cannot use the **-size** parameter to shrink thin-provisioned or compressed volumes that were created from a data reduction pool.

User response

Retry the command and specify a regular disk or a disk from a regular pool.

CMMVC9266E The command has failed because specified host port group id is different from the failover port's host port group id.

Explanation

The system administrator used the **-hpgid** parameter to assign a host port group ID that did not match the host port group ID of the failover port. This error occurs only when the administrator manually edits the `svc_config.backup.xml` file that is used in T3 or T4 recovery.

User response

Retry the command and assign the same host port group ID that is used for the failover port.

CMMVC9267E The command has failed because more than 4 ports are being

assigned the same host port group id.

Explanation

The system administrator used the **-hpgid** parameter to assign the same host port group ID to more than four ports. This error occurs only when the administrator manually edits the `svc_config.backup.xml` file that is used in T3 or T4 recovery.

User response

Retry the command and assign a host port group ID that is not already used for four ports.

CMMVC9268E Network connection refused.

Explanation

The network cannot connect to `api.service.softlayer.com`.

User response

Configure the network so that you can reach `api.service.softlayer.com`. Then, retry the command.

CMMVC9269E The specified storage was not found.

Explanation

An attempt was made to configure IBM Cloud backend storage where the **-storage** parameter referred to an invalid IBM Cloud storage name.

User response

Retry the command and use a valid IBM Cloud storage name.

CMMVC9270E Invalid username or key.

Explanation

An attempt was made to configure IBM Cloud backend storage where the value of the **-username** parameter or the **-key** parameter was not valid.

User response

Refer to the IBM Cloud user portal to obtain the correct IBM Cloud API user name or IBM Cloud API key. Retry the command with valid values.

CMMVC9271E Storage access control error, possibly due to duplicate iSCSI qualified name (IQN) on IBM Cloud.

Explanation

A storage access control error occurred, possibly due to duplicate IQNs on different bare metal servers that were detected on IBM Cloud.

User response

Ensure that the IQN on each bare metal server is unique, and then retry the command.

CMMVC9272E	The specified storage has already been configured.
-------------------	---

Explanation

The **-storage** parameter refers to IBM Cloud storage that is already configured.

User response

If you specified the correct IBM Cloud storage name, no further action is necessary. If the name you specified was incorrect, retry the command with the correct storage name.

CMMVC9273E	The specified storage is already in use by another cluster.
-------------------	--

Explanation

The **-storage** parameter refers to IBM Cloud storage that is already in use by another cluster.

User response

Retry the command and specify a valid storage name.

CMMVC9274E	Some of the serial numbers are not correct.
-------------------	--

Explanation

The product panel name is a unique serial number from the IBM Cloud web page. This name is a mandatory parameter for the **initnode** command. The **initnode** command was run with an incorrect serial number.

User response

Retry the **initnode** command with the correct serial number. Then, retry the **cfgcloudstorage** command.

CMMVC9277E	The command failed because there are out of sync volume mirrors and some copies are in data reduction pools that may also be deleted.
-------------------	--

Explanation

The **rmmdiskgrp** command was attempted when at least one volume mirror is out of sync and the out-of-sync copy is in a data reduction pool.

User response

Synchronize the volume mirrors in all cases where the volume copy is in a data reduction pool. Then retry the **rmmdiskgrp** command.

CMMVC9278E	Task failed because mirrored volume has a fully allocated copy and -nofmtdisk is specified.
-------------------	--

Explanation

To expand a mirrored volume that is fully allocated, the region of expansion must be formatted to ensure that copies are consistent. In this case, the **-nofmtdisk** parameter cannot be used to skip formatting.

User response

Retry the command, omitting the **-nofmtdisk** parameter.

CMMVC9279E	The task failed because there is no up-to-date node in the IO group that contains the volume.
-------------------	--

Explanation

This error can occur when both nodes in the I/O group of the volume are offline, or when some nodes in the I/O group are online but they have stale information.

User response

Ensure that each node in the I/O group is online and has no stale information, and then retry the command. Ensure that the nodes stay online while the command runs.

CMMVC9280E	The command did not complete because creating mirror bitmap is not finished within the allotted time period.
-------------------	---

Explanation

The mirror bitmap must be created successfully before the command can continue. The maximum amount of time that is allotted for the command expired while the bitmap was being created.

User response

Run the command again. If the problem persists, contact IBM Support.

CMMVC9281E **One or more of the nodes in the selected I/O group has no working compression hardware.**

Explanation:

It is not possible to create a compressed volume in an I/O group that has nodes with no working compression hardware. Before you create a compressed volume, the issue with the hardware needs to be fixed.

User response:

View the event log and follow the directed maintenance procedure to fix the issue with the compression hardware.

CMMVC9282E **The specified iSCSI Storage port uses per node credentials. Resetting credentials for all nodes can temporarily cause MDisks to go offline. Use the -f option to make this change.**

Explanation

An attempt was made to reset the authentication credentials for all initiator nodes in the system by running a single command on the command line. This action can be completed only when the **-f** (force) option is used.

User response

Complete one of the following actions:

- Retry the command for a single initiator node.
- Retry the command for all initiator nodes in the system and include the **-f** (force) option.

CMMVC9283E **The command failed because one of the storage pools for the volume is a data reduction pool that has insufficient capacity.**

Explanation

Insufficient capacity exists within the pool that is specified to be able to create a thin or compressed volume within a data reduction pool.

User response

Add extra capacity to the specified storage pool and then run the command again.

CMMVC9284E **The command failed because the pool specified is a data reduction pool that contains offline volumes.**

Explanation

An attempt was made to create a volume in a data reduction pool where one or more volumes are offline. Volumes can be offline for any of the following reasons:

- The data reduction pool is out of capacity.
- The data reduction pool is corrupt.
- The data reduction pool contains corrupt volumes.
- The data reduction pool contains offline MDisks.

User response

Resolve the problem that is causing the volume or volumes to be held offline and retry the command. You might need to complete any of the following tasks:

- Add capacity to the data reduction pool by using the **addmdisk** command, or use the **mkarray** command if you use internal drives.
- Repair corrupt volumes.
- Repair a corrupt data reduction pool by using the **recovervdisk** command.

CMMVC9285E **A thin or compressed volume in a data reduction pool cannot be created within this I/O group because the amount of memory configured for FlashCopy is greater than 1.5 gigabytes (GB) and there is insufficient free memory in the I/O group.**

Explanation

For I/O groups that contain 8 GB node types, thin or compressed volumes cannot be created if the FlashCopy bitmap is larger than 1.5 GB.

User response

Complete one of the following actions:

- Upgrade the node types within the I/O group to contain more than 8 GB of memory.
- Remove data reduction volumes within the specified I/O group.
- Select another I/O group to create the thin or compressed volumes in a data reduction pool.
- Reduce the amount of FlashCopy bitmap memory that is in use for the I/O group to below 1.5 GB.

Then, retry the original command.

CMMVC9286E **The amount of memory configured for FlashCopy cannot be greater than 1.5 gigabytes (GB) because**

data reduction volumes exist in this I/O group

Explanation

For I/O groups that contain 8 GB node types and thin or compressed volumes, the FlashCopy bitmap cannot be increased beyond 1.5 GB.

User response

Complete one of the following actions:

- Upgrade the node types within the I/O group to contain more than 8 GB of memory.
- Remove any data reduction volumes within that I/O group.
- Set the FlashCopy bitmap size under 1.5 GB.
- Specify a different I/O group to use for flash copies.

Then, retry the original command.

CMMVC9287E The volume or volume copy cannot be deleted because the data reduction pool is corrupt.

Explanation

An attempt was made to delete a volume when the data reduction pool where it was located was marked as corrupted.

User response

Complete one of the following actions:

- Repair the data reduction pool by using the **recovervdisk** command.
- Delete the entire pool by using the **rmmdiskgrp -force** command.

CMMVC9288E The node could not be added as a data reduction pool containing a thin or compressed volume exists within this I/O group and the new node does not meet the minimum CPU requirements.

Explanation

When the first thin or compressed volume in a data reduction pool is created for an I/O group, the I/O group sets a minimum CPU threshold. This threshold is based on the lowest number of CPU resources available to any node in the I/O group. A new node with fewer CPU resources cannot be added to the I/O group.

User response

Complete one of the following actions:

- If possible, add another CPU to the node.
- Specify a different node with the same type and CPU as the nodes that are currently in the system.
- If neither of the previous options is available, delete all thin and compressed volumes in all data reduction pools for the specified IO group.

Then, retry the **addnode** command.

CMMVC9289E The command failed because the drives selected have an incompatible combination of technology type and transport protocol.

Explanation

This error occurs when an attempt is made to mix NVMe drives in an array with drives that use a different transport protocol or technology type.

User response

Create an array that uses only SAS drives, or only NVMe drives of a single technology type. Ensure that any drives added to the array are compatible with the existing array members.

CMMVC9290E The mkarray command failed because -level raid5 and raid6 are not supported by this IO group.

Explanation

This error occurs because the hardware for the I/O group does not support the specified RAID level.

On FlashSystem 9100, FlashSystem 9200, and Storwize V7000 2076-724, the **mkarray** command can create only RAID 10 arrays. Use the **mkdistributedarray** command to create RAID 5 or RAID 6 arrays.

User response

Create an array that uses a supported RAID level.

CMMVC9291E Task failed because volume is non-mirrored with fully allocated copy and is part of a Metro Mirror or Global Mirror relationship with -nofmtdisk specified

Explanation

To expand a non-mirrored volume that is fully allocated and that is part of a Metro Mirror or Global

Mirror relationship, the region of expansion must be formatted. In this case, the **-nofmtdisk** parameter cannot be used to skip formatting.

User response

Retry the command, omitting the **-nofmtdisk** parameter.

CMMVC9292E **An IO group can not contain deduplicated volumes or volume copies in data reduction pools at the same time as compressed volumes or volume copies in regular storage pools.**

Explanation

Deduplicated volumes and volume copies cannot be created in an I/O group when compressed volumes or volume copies are in regular storage pools.

User response

Migrate all compressed volumes in the I/O group from regular storage pools to data reduction pools, and then retry the action. Alternatively, create the deduplicated volume or volume copy in a different I/O group.

CMMVC9294E **Unable to add host to storage.**

Explanation

The bare metal server is not authorized as a valid host to the block storage in IBM Cloud.

User response

On the IBM Cloud user portal, authorize the bare metal server as a valid host to the block storage. Then, retry the command.

CMMVC9295E **The command failed because this raid level is not supported with compressed drives.**

Explanation

This error occurs if an attempt is made to create a non-distributed array that uses compressed drives. Non-distributed arrays do not support compressed drives.

User response

Create a distributed array with compressed drives. Ensure that any drives that are used by the array are compatible.

CMMVC9296E **The command has failed because the volume logical block address**

(LBA) supplied is not recoverable and contains a virtual medium error.

Explanation:

The operation has failed because the data at the supplied volume LBA cannot be recovered and the volume LBA cannot look up the physical address.

User response:

Restore the data to the virtual LBA from a backup or from a previously generated backup of the volume or repair the volume from the host application.

CMMVC9298E **The command has failed because there is already an analysis in progress on the specified volume.**

Explanation

An analysis cannot be queued on the specified volume because an analysis is already in progress.

User response

Check whether the correct volume was specified. Check the status of the volume that was specified.

CMMVC9299E **The command has failed because there is not an analysis in progress on the specified volume.**

Explanation

An analysis cannot be canceled on the specified volume because an analysis is not in progress or queued.

User response

Check whether the correct volume was specified. Check the status of the volume that was specified.

CMMVC9300E **The specified IO group does not support deduplication.**

Explanation

Deduplicated volumes and volume copies can be created only in an I/O group where both nodes have a minimum of 32 GB of memory.

User response

Specify an I/O group where both nodes have at least 32 GB of memory.

CMMVC9301E **One of the pools specified is not a data reduction pool and cannot be used to create a deduplicated volume or volume copy.**

Explanation

Deduplicated volumes and volume copies must be created from a data reduction pool.

User response

Use a data reduction pool to create the deduplicated volume or volume copy.

CMMVC9302E The command failed because it is not possible to mix compressed and non-compressed drives in an array.

Explanation

Arrays must contain members that are either all compressed drives or all non-compressed drives.

User response

Select a new drive that has the same compression characteristics as the existing array members.

CMMVC9303E The command failed because one or more required drives did not complete format.

Explanation

This error occurs when one or more drives that are candidates for use in an array do not complete the formatting process in the required time. All NVMe drives in the system must be formatted before an array can be created.

User response

Wait for the formatting process to complete for all drives. You can use the **lsdriveprogress** command to monitor the formatting process.

CMMVC9304E The command failed because the driveclass does not support the specified number of rebuild areas.

Explanation

The number of rebuild areas is not valid for the drive class. This error can occur when an attempt is made to expand a thin-provisioned array and to add rebuild areas to the array simultaneously, which is not supported.

User response

If the error occurred during array creation, retry the command and specify fewer rebuild areas for the same drive class.

If the error occurred during expansion of a thin-provisioned array, retry the command but do not attempt to add rebuild areas to the array.

CMMVC9305E The Cloud Call Home feature is not supported on this platform.

Explanation

This system does not support sending Call Home information directly to a server in the cloud.

User response

Not applicable.

CMMVC9306E The Cloud Call Home feature is not enabled.

Explanation

The Call Home function to send notifications to the support center via cloud services is not enabled.

User response

Enable the Call Home function for cloud services by issuing the following command:

```
svctask chcloudcallhome -enable
```

CMMVC9307E No response from the Cloud Call Home service.

Explanation

Call Home information cannot be sent via cloud services. This error can occur if network issues exist or if the cloud services are currently unavailable.

User response

Ensure that port 443 is open in any firewalls to allow secure HTTP connections to the Call Home servers in the cloud.

- If you are using DNS, allow outbound traffic over port 443 to `esupport.ibm.com`.
- If you are not using DNS, allow outbound traffic over port 443 to the following IP addresses: 129.42.54.189, 129.42.56.189, and 129.42.60.189.

CMMVC9308E The command failed because the requested certificate is incompatible with the current SSL protocol level.

Explanation

The requested certificate type does not match the certificate types that are allowed by the current security level setting on the system.

User response

Specify a certificate type that is supported by the current SSL security level. Alternately, use the **chsecurity** command to reduce the SSL security level, and then retry the command.

CMMVC9309E The command failed because the SSL protocol level is incompatible with the current system certificate.

Explanation

The specified level of SSL protocol allows only ciphers that the current certificate does not allow because of the way the certificate is signed. This error occurs when the combination of the specific security level and the currently stored certificate would prevent the GUI from working. For example, this error occurs when a security level is specified that prohibits RSA key exchange, but the current certificate is RSA-signed.

User response

Use the **chsystemcert** command to generate a new system certificate. Specify an SSL certificate key type that is ECDSA, not RSA.

CMMVC9310E The command failed because one or more drive format was still in progress.

Explanation

This error can occur when a drive is being formatted and the **mkarray** command is run, if the formatting process did not complete in the allotted time.

User response

Retry the command after the format completes. You can use the **lsdriveprogress** command to view the progress of the formatting process.

CMMVC9312E The command failed because a compressed drive cannot be exchanged with a compressed drive of a different drive class.

Explanation

In an array of compressed drives, all members must have the same drive class.

User response

Exchange the member drive with a compressed drive that has the same drive class.

CMMVC9315E The create failed because there are no IO groups supporting deduplication.

Explanation

Deduplicated volumes and volume copies can be created only in an I/O group where both nodes have a minimum of 32 GB of memory.

User response

Specify an I/O group where both nodes have at least 32 GB of memory.

CMMVC9316E The create failed because there are no IO groups supporting deduplication in site

Explanation

Deduplicated volumes and volume copies can be created only in an I/O group where both nodes have a minimum of 32 GB of memory.

User response

Specify a site that contains an I/O group where both nodes have at least 32 GB of memory.

CMMVC9318E Compressed volumes in the selected I/O group must be in a data reduction pool.

Explanation

An operation was attempted that would result in storing a real-time compressed volume copy in an I/O group that does not support real-time compression.

User response

Retry the command and specify either an I/O group that supports real-time compression, or specify a data reduction storage pool.

CMMVC9319E Volumes or volume copies which are thin provisioned or compressed and created from a data reduction pool can only be repaired with the assistance of support.

Explanation

This error is displayed when the **repairsevdiskcopy** command is run on a disk in a data reduction pool.

User response

Contact IBM Support Center for assistance.

CMMVC9321E	Inventory data is not yet available. Please retry the command in a few minutes.
-------------------	--

Explanation

Immediately after cluster creation, manual update, or failover, inventory data is not available for a short time because it is being gathered in the background.

User response

Wait a few minutes and then retry the command.

CMMVC9322E	The command failed because this strip size is not supported by this IO group.
-------------------	--

Explanation:

The hardware for the I/O group does not support arrays with a strip size of 128 KB.

User response

Create an array that uses a strip size of 256 KB.

CMMVC9323E	The command failed because the specified host protocol is not compatible with the specified port type.
-------------------	---

Explanation

A host that uses the Non-Volatile Memory express (NVMe) protocol can contain only NVMe Qualified Names (NQN). A host that uses the SCSI protocol cannot contain NQNs.

User response

For a host that uses the NVMe protocol, use the **-nvmenqn** parameter to supply a list of NQNs to add to the host. For a host that uses the SCSI protocol, use the **-fcwwpn**, **-iscsiname**, or **-saswwpn** parameter to supply a list of ports to add to the host.

CMMVC9324E	The command failed because the specified host type is not compatible with the specified protocol.
-------------------	--

Explanation

A host that uses the Non-Volatile Memory express (NVMe) protocol must be of type **generic**. Other host types are not supported.

User response

Change the host protocol or type, and then retry the command.

CMMVC9325E	The command failed because the maximum number of host ports for the system would be exceeded.
-------------------	--

Explanation

Adding the specified ports would result in a total number of host ports that exceed the limit that can be configured on the system.

User response

Remove unused hosts or host ports, and then retry the command.

CMMVC9326E	The command failed because the maximum number of host ports for an I/O group would be exceeded.
-------------------	--

Explanation

Adding the specified ports would result in a total number of host ports that exceeds the limit that can be configured in an I/O group.

User response

Identify I/O groups where the limit would be exceeded and remove unused hosts or host ports, then retry the command. Alternately, specify a different set of I/O groups that the host can access volumes from.

CMMVC9327E	The command failed because the maximum number of NQNs for an I/O group would be exceeded.
-------------------	--

Explanation

Adding the specified NVMe Qualified Names (NQNs) would result in a total number of NQNs that exceeds the limit that can be configured in an I/O group.

User response

Identify I/O groups where the limit would be exceeded and remove unused NVMe hosts or NQNs, and then retry the command. Alternately, specify a different set of I/O groups that the host can access volumes from.

CMMVC9328E **The command failed because one of the specified NQNs is already assigned to a host.**

Explanation

A Non-Volatile Memory express Qualified Name (NQN) can be assigned to only one host. NQNs that differ only by case are not considered to be unique.

User response

Identify the existing host that contains the specified NQN. Remove the NQN from that host, and then retry the command.

CMMVC9329E **The command failed because the specified host type is not compatible with the current host protocol.**

Explanation

A host that uses the Non-Volatile Memory Express (NVMe) protocol must be of type **generic**.

User response

You cannot change the host type for a host that uses the NVMe protocol.

CMMVC9330E **The command failed because the specified host protocol is not compatible with the current host type.**

Explanation

A host that uses the Non-Volatile Memory express (NVMe) protocol must be of type **generic**.

User response

Change the host type to **generic**, and then retry the command to change the host protocol.

CMMVC9331E **The host protocol cannot be changed because the host has ports configured.**

Explanation

The host protocol cannot be changed while ports are configured for the host.

User response

Remove all ports from the host, and then retry the command.

CMMVC9332E **The host protocol cannot be changed because there are volumes mapped to the host.**

Explanation

The host protocol cannot be changed while volumes are mapped to the host.

User response

Remove all mappings to the host, and then retry the command.

CMMVC9334E **The command failed as the volume is already mapped to host/s with a protocol inconsistent with the specified host.**

Explanation

The volume cannot be mapped to hosts that use the SCSI protocol and to hosts that use the NVMe protocol.

User response

Ensure that all the hosts that are mapped to the volume use the same protocol.

CMMVC9335E **The command failed as the -scsi parameter is not supported for hosts with protocol set as NVMe.**

Explanation

The SCSI ID cannot be specified when you map a volume to a host that uses the NVMe protocol.

User response

Retry the command without specifying the **-scsi** parameter.

CMMVC9336E **The command failed because the system does not support NVMe host attachment.**

Explanation

The system does not support host connections that use the Non-Volatile Memory express (NVMe) protocol.

User response

Use an alternative protocol for host connections.

CMMVC9337E **The command failed because the specified port type is not compatible with the host protocol.**

Explanation

A host that uses the Non-Volatile Memory express (NVMe) protocol can contain only NVMe Qualified Names (NQN). A host that uses the SCSI protocol cannot contain NQNs.

User response

For a host that uses the NVMe protocol, use the **-nqn** parameter to supply a list of NQNs to add to the host.

For a host that uses the SCSI protocol, use the **-fcwwpn**, **-iscsiname**, or **-saswwpn** parameter to supply a list of ports to add to the host.

CMMVC9338E **The command failed because the maximum number of ports for the host would be exceeded.**

Explanation

Adding the specified ports would result in a total number of ports that exceed the limit that can be configured for a host.

User response

Identify and remove any unused ports from the host before you retry the command. Alternately, create a host that uses the specified ports.

CMMVC9339E **The command failed because the maximum number of NQNs for the host would be exceeded.**

Explanation

Adding the specified Non-Volatile Memory express (NVMe) Qualified Names would result in the total number of NQNs exceeding the limit that can be configured for a host.

User response

Identify and remove any unused NQNs from the host before you retry the command. Alternately, create a new host that uses the specified NQNs.

CMMVC9340E **The command failed because the specified NQN is not assigned to the specified host.**

Explanation

The specified NVMe Qualified Name (NQN) cannot be removed because it is not assigned to the specified host.

User response

Check the specified NQN and host, and then retry the command and specify an NQN that is assigned to the host.

CMMVC9341E **The command failed because Source IP Address specified via -src_ip parameter does not exist or port id specified via -src_port_id parameter does not exist.**

Explanation

This error can occur if the specified source IP address or port ID does not exist. The source IP address and port ID must be in the list that is displayed by the **svcinfo lsportip** command.

User response

Run the **svcinfo lsportip** command to determine the correct source IP address and port ID to specify.

CMMVC9342E **The command failed because Node ID specified via -node_id parameter does not exist or is in OFFLINE state.**

Explanation

This error can occur if the specified node is not active.

User response

Specify the ID of a node that has active or online status, as shown by the **svcinfo lsnode** or **svcinfo lsnodecanister** commands.

CMMVC9343E **The command failed because the host protocol does not match the existing hosts in the host cluster.**

Explanation

All hosts in a host cluster must use the same protocol.

User response

Specify a host cluster that uses a protocol that matches the protocol of the host.

CMMVC9344E **The command failed because the protocols of the specified hosts are different.**

Explanation

All hosts in a host cluster must use the same protocol.

User response

Specify hosts that use the same protocol.

CMMVC9345E The host protocol cannot be changed because the host is a member of a host cluster.

Explanation

All hosts in a host cluster must use the same protocol.

User response

Remove the host from the host cluster, and then retry the command.

CMMVC9346E The command failed because the volume is mapped to hosts using the NVMe protocol.

Explanation

A volume that is accessed by hosts that use the NVMe protocol cannot be configured with multiple access I/O groups. HyperSwap volumes require at least one access I/O group to be configured in each site for proper operation.

User response

Change the host to access storage by using the SCSI protocol if access to a HyperSwap volume is needed.

CMMVC9347E The command failed because the volume is mapped to hosts using the NVMe protocol.

Explanation

A volume that is accessed by hosts that use the NVMe protocol cannot be configured with multiple access I/O groups.

User response

Change the host to access storage by using the SCSI protocol if multiple access I/O groups are needed.

CMMVC9349E The command failed because a host using the NVMe protocol cannot be mapped to a volume with multiple access I/O groups configured.

Explanation

A host that uses the NVMe protocol cannot be mapped to a volume with multiple access I/O groups configured.

User response

Change the host to access storage by using the SCSI protocol if multiple access I/O groups are needed. Alternatively, remove the additional access I/O groups from the volume access set so that the volume is accessible through only a single I/O group.

CMMVC9351E The command failed because a host using the NVMe protocol cannot be mapped to a volume with multiple access I/O groups configured.

Explanation

A host that uses the NVMe protocol cannot be mapped to a volume with multiple access I/O groups configured.

User response

Change the hosts in the host cluster to access storage by using the SCSI protocol if multiple access I/O groups are needed. Alternatively, remove the additional access I/O groups from the volume access set so that the volume is accessible through only a single I/O group.

CMMVC9352E The command failed as the volume is already mapped to hosts with a protocol inconsistent with the specified host cluster.

Explanation

A volume cannot be mapped to host clusters that use the SCSI protocol and to host clusters that use the NVMe protocol at the same time.

User response

Make sure that all of the host clusters that are mapped to the volume use the same protocol.

CMMVC9353E The command failed as the -scsi parameter is not supported for host clusters with protocol set as NVMe.

Explanation

The SCSI ID cannot be specified when you map a volume to a host cluster that uses the NVMe protocol.

User response

Retry the command, omitting the **-scsi** parameter.

CMMVC9354E The command failed because the array has an expansion ongoing.

Explanation

This error can occur when an attempt is made to start another array expansion or to change members of a managed disk while an array expansion is already in progress.

User response

- To remove a drive from membership in the array, use the **chdrive -failed** command.
- To change the membership of the array, use the **charraymember -immediate** command.
- To expand the array, wait until the current expansion process completes, and then retry the command. You can monitor the expansion process by using the **lsarrayexpansionprogress** command.

CMMVC9355E **The command failed because the array has a member resync ongoing.**

Explanation

This error can occur when an attempt is made to run a command while array member synchronization is happening because of high latency.

User response

Wait for the synchronization process to complete, and then retry the command. You can monitor the synchronization process by using the **lsarraymemberprogress** command.

CMMVC9356E **The command failed because an array in the parent pool has an expansion ongoing.**

Explanation

This error can occur when an attempt is made to expand an array when there is already an array in the parent pool that is being expanded. Only one array per parent pool can be expanded at a time.

User response

Wait for the current expansion process to complete, and then retry the command. You can monitor the expansion process by using the **lsarrayexpansionprogress** command.

CMMVC9357E **The command failed because the array does not support expansion.**

Explanation

This error can occur when an attempt is made to expand an unsupported array. Array expansion is supported only on distributed arrays of SAS drives.

User response

Run the command on a distributed array of SAS drives.

CMMVC9358E **An unknown error condition occurred while setting up the self encrypting drives.**

Explanation

An unspecified error occurred while encryption was being configured on one or more drives.

User response

Format the candidate drives, and then retry the command. If the issue persists, contact IBM Support Center.

CMMVC9359E **The command failed because the system has reached the maximum number of ongoing expansions.**

Explanation

This error can occur when an attempt is made to expand too many arrays. Only four arrays and only one array per storage pool can be expanded at the same time.

User response

Wait for an array expansion to complete, and then retry the command. You can monitor the expansion process by using the **lsarrayexpansionprogress** command.

CMMVC9360E **The command failed because the array specified is offline.**

Explanation

This error can occur when an attempt is made to expand an array that is offline.

User response

Bring the array online, and then retry the command. You can use the **lsarray** command to check the status of an array.

CMMVC9361E **The command failed because the array has rebuild areas in use**

Explanation

This error can occur when an attempt is made to expand an array that has rebuild areas that are in use. To run an expansion, all rebuild areas must be inactive.

User response

- Fix any errors that are associated with the drives in the array.
- Run the **lsarray** command until the number of rebuild areas available (rebuild_areas_available) is the same as the total number of rebuild areas (rebuild_areas_total). When the number of available rebuild areas is the same as the total number of rebuild areas, the rebuild areas are inactive.
- Retry the command.

CMMVC9362E **The command failed because authentication credentials are not set by chiscsiportauth CLI.**

Explanation

If the authentication information is not set for a node port, an empty source iSCSI qualified name (IQN) is used. An iSCSI login message cannot contain an empty source IQN. This error applies to IBM Cloud only.

User response

Use the **chiscsiportauth** command to set the authentication information for the port on the configuration node.

CMMVC9363E **The command failed because the array specified has a component in doubt.**

Explanation

This error can occur when an attempt is made to expand an array that has components that might be about to fail.

User response

Fix all errors that are related to the specified array, and then retry the command.

CMMVC9364E **The command failed because the array status was not stable when the command was executed. Please retry the command if you want to carry on with the expansion.**

Explanation

This error can occur when the status of an array changes during an expansion process.

User response

Wait until the array status is stable, and then retry the command. You can use the **lsarray** command to determine the status of an array.

CMMVC9365E **The node cannot be removed because it would result in an I/O group outage. Use -force flag to override.**

Explanation

The **rmnode** command cannot be used to remove the last node in an I/O group unless you specify the **-force** parameter.

User response

Ensure that you want to remove the last node in the I/O group. If you are certain that you want to remove the last node in the I/O group, enter the **rmnode** command with the **-force** parameter.

CMMVC9366E **The command failed because the additional drive count must exceed the additional rebuild area count.**

Explanation

This error occurs when an attempt is made to expand an array, but the number of rebuild areas to add is greater than or equal to the number of drives to add.

User response

Retry the command, specifying a number of drives to add that is greater than the number of rebuild areas to add.

CMMVC9368E **The command failed because the additional rebuild area count would result in the array exceeding the maximum rebuild area count.**

Explanation

This error occurs when an attempt is made to expand an array, but the specified number of rebuild areas to add is not supported. The maximum number of rebuild areas is four.

User response

Retry the command, specifying a number of rebuild areas to add that does not exceed the maximum.

CMMVC9369E The command failed because there are no IO groups that support both compression and deduplication

Explanation

A compressed and deduplicated volume cannot be created in the clustered system because no I/O group that supports both deduplication and compression is available.

This message is displayed when the clustered system contains I/O groups that support compression but not deduplication and I/O groups that support deduplication but not compression, but contains no I/O groups that support both deduplication and compression.

User response

Add an I/O group that supports both compression and deduplication to the system.

CMMVC9370E The command failed because there are no IO groups that support both compression and deduplication in site *site_id*.

Explanation

A compressed and deduplicated volume cannot be created in the clustered system at the specified site because no I/O group that supports both deduplication and compression is available.

This message is displayed when the clustered system contains I/O groups that support compression but not deduplication and I/O groups that support deduplication but not compression, but contains no I/O groups that support both deduplication and compression.

User response

Add an I/O group that supports both compression and deduplication to the site.

CMMVC9371E The command failed because the I/O group specified is not in the same site as the storage pool.

Explanation

Creating a volume with a thin or compressed copy in a data reduction pool on a different site from the site of the I/O group is not allowed.

This message is displayed when an attempt is made to create a thin or compressed volume with a copy in a data reduction pool on a system that uses a HyperSwap topology.

User response

Retry the command, specifying storage pools that are on the same site as the I/O group of the volume.

CMMVC9372E The command failed because the storage pool specified is not in the same site as the volume.

Explanation

Creating a thin or compressed volume copy in a data reduction pool on a different site from the I/O group of the volume is not allowed.

This message is displayed when an attempt is made to create a thin or compressed volume copy in a data reduction pool on a system that uses a HyperSwap topology.

User response

Retry the command, specifying a storage pool on the same site as the I/O group of the volume.

CMMVC9373E The command failed because the drive is only supported for Distributed Arrays, which do not use spares.

Explanation

An attempt was made to change the role of a FlashCore Module (FCM) so that it can be used as a hot-spare drive. This error can occur when the `chdrive -use spare drive_id` command is run on an FCM. Only distributed arrays are supported on FCMs. FCMs cannot be used as hot-spare drives.

User response

Do not attempt to change the role of an FCM so that it can be used as a hot-spare drive. If you are replacing failed drives in an array, insert the replacement drives directly into the same slot as the failed drive, which causes the system to automatically configure the FCM as a replacement member.

If the role of the replacement drive was already changed, inserting it in the same slot does not cause the system to automatically replace the previous member drive in the array. In this situation, use the **charraymember** command to add the replacement candidate drive directly into the array. Change the role of the old drive to **unused** to remove it from the system.

If the member drive was removed from the array by changing its role from **failed** to **unused**, you must use the **chararraymember** command to service the array.

CMMVC9374E The command failed because volume mappings exist and the host is a member of a host cluster.

Explanation

This error can occur when an attempt is made to delete mappings between I/O groups and a host when the host is a member of a host cluster and is mapped to volumes in the I/O groups that are being removed.

User response

Remove the host from the host cluster, and then retry the command.

CMMVC9375E The command failed because the volume is already mapped to another host. Use -force to create the mapping.

Explanation

This error can occur when an attempt is made to create a mapping between a volume and a host, when the volume is already mapped to another host. If a volume is mapped to multiple hosts, the hosts must coordinate access to avoid corrupting data.

User response

To map the volume to multiple hosts, create the mapping by retrying the command and specifying the **-force** flag. Otherwise, remove the existing host mapping to the volume and then retry the command.

CMMVC9376E The node could not be added as the code level of new node is different with the code level of the cluster in this platform.

Explanation

This error can occur when an attempt is made to add a cloud node that is running a different version of software from the existing system.

User response

Install the same version of software on the new cloud node as is installed on the existing system, and then add the node to the system.

CMMVC9377W There are dependent FlashCopy mappings not in your ownership group.

Explanation

This warning occurs when all dependent FlashCopy mappings cannot be displayed because some of the mappings are not in the ownership group of the user who ran the command.

User response

There is no user response. If you delete a FlashCopy mapping that you own, it can affect other objects outside your ownership group.

CMMVC9378E The command failed because the specified ownership group is associated with one or more objects. To continue specify -keepobjects.

Explanation

This error can occur if an attempt is made to delete an ownership group that is still associated with objects.

User response

Complete one of the following steps:

- To remove the ownership group without removing the associated objects from the system, retry the command and specify the **-keepobjects** option.
- Change or delete the ownership group for all associated objects, and then retry the command.

CMMVC9379E The command failed because it cannot be executed by a user in an ownership group.

Explanation

This error can occur if a command is specified that affect objects that are not in the user's ownership group.

User response

Contact someone with the Administrator or Security Administrator role and have them run the command.

CMMVC9380E The command failed because quorum site cannot be set in standard quorum mode.

Explanation

This error can occur when an attempt is made to assign a quorum site while in standard quorum mode. Quorum mode can be set to standard, winner, or preferred.

User response

Use the **chsystem -quorummode** command to change the quorum mode to winner or preferred, and then retry the command.

CMMVC9381E The required update package can not be found and downloaded from the support server in this platform.

Explanation

When the **svctask applysoftware** command runs, the software package is downloaded from the support server. This error can occur if the software package is not downloaded from the support server to the configuration node when the **svctask applysoftware** command runs.

User response

Check the network connectivity between the configuration node and the support server, and then retry the command. If the error message is displayed again, contact IBM Support Center.

CMMVC9383E The command failed because changing MTU value is not allowed for ethernet port which is already configured for RDMA clustering.

Explanation

This error can occur if an attempt is made to change the maximum transmission unit (MTU) value of an RDMA-capable Ethernet port while the port is configured for RDMA clustering.

User response

Change the MTU value for RDMA-capable Ethernet ports only on ports that are not configured for RDMA clustering.

CMMVC9384E The command failed because the specified ownership group does not exist.

Explanation

This error occurs when a command is run that specifies an ownership group that does not exist.

User response

Retry the command, specifying an ownership group that exists.

CMMVC9385E The command failed because one or more parameters cannot be

specified by a user in an ownership group.

Explanation

This error can occur if a parameter is specified that would affect objects that are not in the user's ownership group.

User response

Contact someone with the Administrator or Security Administrator role and have them run the command.

CMMVC9386E The command failed because it would result in inconsistent ownership groups and the - inconsistentownershipgroup parameter was not specified.

Explanation

This error can occur if an attempt is made to run a command that would result in an inconsistent ownership groups, and the **- inconsistentownershipgroup** parameter is not specified. For example, this error is displayed if the result of a command would be that related objects are in different ownership groups.

User response

Retry the command, specifying the **- inconsistentownershipgroup** parameter to use different ownership groups for related objects.

CMMVC9387E The command failed because the seeding hosts are in more than one ownership group.

Explanation

This error occurs when an attempt is made to create a host cluster that specifies seeding hosts that are in different ownership groups.

User response

Retry the command, specifying a list of seeding hosts that are in only one ownership group.

CMMVC9388E The command failed because seeding hosts were owned and that ownership group needs to be specified using the - ownershipgroup parameter.

Explanation

This error can occur when an attempt is made to create a host cluster and the seeding hosts are in an

ownership group but the ownership group is not specified.

User response

Retry the command, specifying the **-ownershipgroup** parameter.

CMMVC9389E The command failed because there are already max iSCSI (initiator + target) sessions present on node.

Explanation

This error can occur when an attempt is made to establish more than 1024 iSCSI connections on a node, including host attachment and external storage connections.

User response

Remove unneeded iSCSI connections, and then retry the command. You might need to remove host attachment connections to create more iSCSI connections to external storage.

CMMVC9390E The command failed because the SecurityAdmin group and ownership groups are mutually exclusive.

Explanation

This error can occur if an attempt is made to run a command that would result in an ownership group that is also a user group with SecurityAdmin privileges.

User response

Retry the command, specifying a user group that either has no ownership group or no SecurityAdmin privileges.

CMMVC9391E The command failed because the thin provisioned array is write protected.

Explanation

This error can occur when an attempt is made to expand an array that is in a read-only state because the array has no free physical capacity.

User response

Free up space on the array by moving volumes to other arrays or by deleting volumes, and then retry the command. If volumes cannot be moved or deleted, contact IBM Support Center.

CMMVC9392E The command failed because the cache state for a volume or copy is corrupt.

Explanation

This error can occur if the cache for a volume or volume copy is corrupted.

User response

Use the **recovervdisk** command to recover the volume and bring it back online, and then retry the command.

CMMVC9393E The network is unreachable.

Explanation

This error can occur when the system is unable to communicate with the Amazon Virtual Private Cloud (VPC) endpoint to access the Amazon Elastic Compute Cloud (EC2).

User response

- Check network settings and modify them as needed to establish a connection with the VPC endpoint.
- Ensure that DNS is configured correctly on the system.

CMMVC9394E The node is not authorized to complete this operation.

Explanation

This error can occur when the Identity and Access Management (IAM) role does not have the permissions that are required to run the command. Access in Amazon Web Services (AWS) is managed by creating policies and attaching them to IAM roles. IAM roles are then assigned to Elastic Compute Cloud (EC2) instances. An IAM role with the required permissions is bundled with the product.

User response

Follow the Directed Maintenance Procedures (DMP) to log on to the AWS management console and add the required permissions to the IAM role of the EC2 instance.

CMMVC9395E The specified local managed disk is not in a valid state.

Explanation

This error can occur if an attempt is made to add local managed disks to a storage pool or image volume when the managed disks are not in the available or

in-use state and in the unmanaged access mode. Local managed disks are cloud storage that is located on Amazon Elastic Block Storage (EBS) volumes.

User response

Select a local managed disk that is in the available or in-use state and in the unmanaged access mode, and then retry the command. You can use the **lslocaldisk** command to determine the states of local managed disks.

CMMVC9396E **The system already manages the maximum number of local managed disks.**

Explanation

This error can occur when an attempt is made to manage more than 16 local managed disks on a system. Local managed disks are cloud storage that is located on Amazon Elastic Block Storage (EBS) volumes.

User response

Do not attempt to manage more than 16 local managed disks on a system.

CMMVC9397E **The local managed disks were not attached to the node in the allotted time.**

Explanation

This error can occur when an attempt is made to add multiple Amazon Elastic Block Storage (EBS) volumes as local managed disks. If all of the EBS volumes are not attached to the system node within 160 seconds of entering the command, this error message is displayed. Local managed disks are cloud storage that is located on Amazon Elastic Block Storage (EBS) volumes.

User response

Retry the command, adding fewer managed disks. If the error occurs when you attempt to add a single local managed disk, check the event log, resolved all unfixed errors, and then resubmit the command.

CMMVC9399E **The command failed because the EasyTier FCM over allocation max ratio is out of range.**

Explanation

This error occurs when the specified IBM Easy Tier overallocation maximum ratio for a FlashCore Module (FCM) is out of range. The supported range for the

overallocation maximum ratio is between 100% and 400%.

User response

Retry the command and specify an overallocation maximum ratio between 100% and 400%.

CMMVC9402E **The SCSI LUN ID currently allocated to the volume mapping is not available in all of the new access IO groups.**

Explanation

This error can occur when a SCSI LUN ID is not available in all of the access I/O groups that are being added. The specified volume mapping has a SCSI LUN ID that is allocated to it in the access I/O groups in the current access I/O group set. The SCSI LUN ID is the same for all access I/O groups in the access I/O group set, but is not available in all of the new access I/O groups that are being added.

User response

Remove the host mapping in the new access I/O groups that is using the required SCSI LUN ID and then retry the command. Alternately, if the host supports mismatched SCSI LUN IDs, use the - **allowmismatchedscsiids** option to assign a different SCSI LUN ID to the volume.

CMMVC9403E **The SCSI LUN IDs currently allocated to the volume mapping are different in existing access IO groups.**

Explanation

This error can occur when the system cannot allocate the same SCSI LUN IDs in all access I/O groups because different SCSI LUN IDs are allocated to the volume mapping in the access I/O groups in the current access I/O group set.

User response

Complete one of the following steps.

- Remove access from the access I/O groups that have mismatched SCSI LUN IDs and then retry the command, including the removed access I/O group and the new access I/O group to allocate matching SCSI LUN IDs. Make sure that the required SCSI LUN ID is available in all access I/O groups.
- Remove the host mapping to the volume that is using different SCSI LUN IDs and then re-create the host mapping, including the new access I/O group with matching SCSI LUN IDs.

- Use the **-allowmismatchedscsiids** option to assign the volume a different SCSI LUN ID from the existing IDs. Not all hosts support this configuration.

CMMVC9404E An identical SCSI LUN ID is not available in all access IO groups.

Explanation

This error can occur when the system is not able to allocate an identical SCSI LUN ID in all the volume access I/O groups because identical SCSI LUN IDs are not available.

User response

Remove host mappings or I/O group access for one or more volumes to free up at least one SCSI LUN ID across all access I/O groups, and then retry the command.

Alternately, specify the **-allowmismatchedscsiids** option to allocate SCSI LUN IDs that are not the same in all the access I/O groups. Not all hosts support this configuration.

CMMVC9405E The command failed as the -allowmismatchedscsiids parameter is not supported for hosts with protocol set as NVMe.

Explanation

This error can occur when the **-allowmismatchedscsiids** option is specified for a volume that is mapped to a host that uses the Non-Volatile Memory express (NVMe) protocol. The **-allowmismatchedscsiids** option is not supported for hosts that use the NVMe protocol.

User response

Retry the command but do not specify the **-allowmismatchedscsiids** option.

CMMVC9406E The FlashCopy mapping or consistency group could not be started as a target volume has received I/O within the defined volume protection period.

Explanation

This error can occur when an attempt is made to start a FlashCopy mapping or consistency group when volume protection is enabled, and the protected volume received I/O operations within the defined volume protection time period.

User response

Ensure that no host I/O operations are being sent to the volume and ensure that you waited for the defined volume protection time period, or disable volume protection.

CMMVC9407E The Remote Copy relationship could not be created as the specified secondary volume has received I/O within the defined volume protection period.

Explanation

This error can occur when an attempt is made to create a remote copy relationship with a secondary volume when volume protection is enabled, and the protected volume received I/O operations within the defined volume protection time period.

User response

Ensure that no host I/O operations are being sent to the secondary volume and ensure that you waited for the defined volume protection time period, or specify a different secondary volume.

Alternately, temporarily disable volume protection on the secondary system.

CMMVC9408E The volume snapshot could not be restored as the volume has received I/O within the defined volume protection period.

Explanation

This error can occur when an attempt is made to restore a snapshot to a volume when volume protection is enabled, and the protected volume received I/O operations within the defined volume protection time period.

User response

Ensure that no host I/O operations are being sent to the volume and ensure that you waited for the defined volume protection time period.

Alternately, temporarily disable volume protection.

CMMVC9409E The volume caching IO group must be included in the volume access IO group set.

Explanation

This error can occur when the specified volume access I/O group set does not include the volume caching I/O group.

User response

Retry the command, specifying a volume access I/O group set that includes the volume caching I/O group.

CMMVC9410E The new caching IO group for the volume must be in the volume access set.

Explanation

This error can occur when the specified caching I/O group for the volume is not in the volume access I/O group set.

User response

Retry the command, specifying a volume caching I/O group that is in the volume access I/O group set.

CMMVC9411E The volume caching IO group cannot be removed from the volume access IO group set.

Explanation

This error can occur when an attempt is made to remove the volume caching I/O group from the volume access I/O group set. The volume access I/O group set must include the volume caching I/O group.

User response

Retry the command, specifying an I/O group that is not the volume caching I/O group. Alternately, change the volume caching I/O group and then retry the command.

CMMVC9412E The command failed because cloud call home requires an active connection.

Explanation

This error can occur when an attempt is made to enable support assistance, but the cloud call home function is not enabled, the network connection to the cloud service is blocked or unavailable, or the cloud service is unavailable.

User response

Complete the following steps:

1. Use the **lscloudcallhome** command or the management GUI to check that the cloud call home function is enabled.
2. If the cloud call home function is disabled, use the **chcloudcallhome -enable** command or the management GUI to enable the function.

3. If the cloud call home function is enabled, ensure that port 443 is open in any firewalls so that secure HTTP connections can be established between the system and the call home servers in the cloud. On systems that use DNS, allow outbound traffic over port 443 to esupport.ibm.com. On systems that do not use DNS, allow outbound traffic on port 443 to the following IP addresses: 129.42.54.189, 129.42.56.189, and 129.42.60.189.

You can use the **sendcloudcallhome -connectiontest** command to test the connection to the cloud service, and then view the test results by using the **lscloudcallhome** command.

CMMVC9413E Cloud call home failed to send remote support assist information.

Explanation

This error occurs when call home information cannot be sent to the cloud service. Typically this error occurs when network issues exist, or when the cloud service is unavailable.

User response

Complete the following steps:

1. Ensure that port 443 is open in any firewalls so that secure HTTP connections can be established between the system and the call home servers in the cloud. On systems that use DNS, allow outbound traffic over port 443 to esupport.ibm.com. On systems that do not use DNS, allow outbound traffic on port 443 to the following IP addresses: 129.42.54.189, 129.42.56.189, and 129.42.60.189.
2. Use the **sendcloudcallhome -connectiontest** command to test the connection to the cloud service, and then view the test results by using the **lscloudcallhome** command.

CMMVC9420E The storage pool cannot be deleted because it has an out of sync volume copy in a storage pool with volume protection active, this copy will be deleted and the volume has received I/O within the defined volume protection period.

Explanation

This error can occur when an attempt is made to delete a storage pool that contains at least one mirrored volume that has an unsynchronized copy in another pool where volume protection is enabled, and the protected volume received I/O operations within the defined volume protection time period.

User response

Ensure that no host I/O operations are being sent to the mirrored volume and ensure that you waited for the defined volume protection time period.

CMMVC9439E The command failed because the thin provisioned array does not have sufficient free physical capacity to start expansion.

Explanation

This error can occur when an attempt is made to expand an array that does not have enough physical free capacity to complete the expansion process.

User response

Free up space on the array by moving volumes to other arrays or by deleting volumes, and then retry the command.

CMMVC9440E The command failed because the snmp engine id format is invalid.

Explanation

This error can occur when an attempt is made to use a Simple Network Management Protocol (SNMP) engine ID that has an invalid format. SNMP engine IDs are composed of a series of octets (bytes). They must be at least five octets long and not more than 32 octets long. Thus, an SNMP engine ID is an even number of hexadecimal characters, 10 - 64 hexadecimal characters long.

User response

Retry the command, specifying an SNMP engine ID in a valid format.

CMMVC9441E The command failed because a post-update background task is in progress.

Explanation

This error can occur during a software update, when the use of some CLI commands is restricted.

User response

Wait for the update process to complete. Typically, the update process takes no longer than 1 hour.

CMMVC9442E The command failed because the specified volume is not a HyperSwap volume.

Explanation

This error occurs when an attempt is made to use the **expandvolume** command to expand a non-HyperSwap volume.

User response

Retry the command, specifying a HyperSwap volume. You can use the **expandvdiskspace** command to expand a non-HyperSwap volume.

CMMVC9443E The command failed because the volume is part of a Remote Copy consistency group.

Explanation

This error can occur when an attempt is made to change the size of a HyperSwap volume while the volume is part of a remote copy consistency group.

User response

Remove the active-active relationship for the volume from the remote copy consistency group, and then retry the command. The active-active relationship can be added back to the consistency group after the volume is expanded.

CMMVC9444E The command failed because the volume is part of a FlashCopy mapping.

Explanation

This error can occur when an attempt is made to expand a HyperSwap volume when the volume is part of a FlashCopy mapping. Only the system-controlled FlashCopy mappings for the change volumes are supported when a HyperSwap volume is expanded.

User response

Remove the FlashCopy mappings for the HyperSwap volume, leaving only the system-controlled FlashCopy mappings for the change volumes, and then retry the command.

CMMVC9445E The command failed because not all copies of the volume are synchronized.

Explanation

This error can occur when an attempt is made to expand a HyperSwap volume when not all copies of the volume are synchronized and online.

User response

Resolve any unfixed errors. Wait until all copies of the volume are synchronized, or remove unsynchronized copies if they are no longer required, and then retry the command.

CMMVC9446E **The command failed because there is not enough memory available for the Remote Copy feature in I/O group ID [%1].**

Explanation

This error can occur when an attempt is made to expand a volume but insufficient memory is available for remote copy processing.

User response

Use the **chiogrp -feature remote** command to increase the amount of memory that is available for remote copy processing in the I/O group, and then retry the command.

CMMVC9447E **The command failed because there is not enough memory available for the FlashCopy feature in I/O group ID [%1].**

Explanation

This error can occur when an attempt is made to expand a volume but insufficient memory is available for FlashCopy services.

User response

Use the **chiogrp -feature flash** command to increase the amount of memory that is available for FlashCopy services in the I/O group, and then retry the command.

CMMVC9448E **The command failed because there is not enough memory available for the Mirroring feature in I/O group ID [%1].**

Explanation

This error can occur when an attempt is made to expand a volume but insufficient memory is available for volume mirroring operations.

User response

Use the **chiogrp -feature mirror** command to increase the amount of memory that is available for volume mirroring operations in the I/O group, and then retry the command.

CMMVC9449E **The command failed because the volume has one or more fully allocated copies.**

Explanation

This error can occur when an attempt is made to expand a HyperSwap volume that has volume copies that are not thin-provisioned or compressed. HyperSwap volumes can be expanded only if all copies of the volume are thin-provisioned or compressed.

User response

Remove any volume copies that are not thin-provisioned or compressed, and then retry the command.

CMMVC9450E **The command failed because the volume has multiple copies in a site.**

Explanation

This error can occur when an attempt is made to expand a HyperSwap volume that has multiple volume copies that are in a single site. HyperSwap volumes can be expanded only when there is one copy of the volume in each site.

User response

Remove one of the mirrored volume copies and then retry the command.

CMMVC9451E **The command failed because the last grain of a volume copy has not been fully formatted.**

Explanation

This error can occur when the volume was created by using a previous version of the system software and the volume has at least one fully allocated copy where the last grain is not fully formatted.

User response

Convert the volume to a basic volume by removing one of the HyperSwap volume copies. Expand the size of the volume and then add a HyperSwap volume copy.

Alternately, convert all fully allocated volume copies of the volume to use thin-provisioning or compression, and then retry the command.

CMMVC9452E **The command failed because the volume has one or more image mode copies.**

Explanation

This error can occur when the HyperSwap volume has image mode copies.

User response

Convert the volume to a basic volume by removing one of the HyperSwap volume copies. Expand the size of the volume and then add a HyperSwap volume copy.

Alternately, convert all image mode copies of the volume to a different volume type, and then retry the command.

CMMVC9453E **The command failed because there are nodes offline or because there are unrecovered Remote Copy relationships or FlashCopy mappings.**

Explanation

This error can occur when the HyperSwap volume has unresolved remote copy or FlashCopy errors or a node is offline.

User response

Resolve the errors and ensure that all nodes are online, and then retry the command.

CMMVC9454E **The command failed because one or more HyperSwap volumes have a copy or a change volume in this pool that must be removed first.**

Explanation

This error can occur when an attempt is made to force the deletion of a storage pool that contains HyperSwap volume copies.

User response

Use the **rmvolume** command to remove all HyperSwap volume copies in the pool, and then retry the command.

CMMVC9455E **The command failed because both [-engineid] and [-securityname] are required to change to version 3 security.**

Explanation

This error can occur when an attempt is made to change from Simple Network Management Protocol (SNMP) version 2 to SNMP version 3 but the engine ID or security name was not specified. To change to

SNMP version 3, both the engine ID and security name must be specified.

User response

Retry the command, specifying both the **-engineID** and **-securityname** parameters.

CMMVC9456E **The command failed because both [-authprotocol] and [-authpassphrase] are required to set up snmp authentication.**

Explanation

This error can occur when an attempt is made to set up Simple Network Management Protocol (SNMP) authentication but the protocol or passphrase was not specified. To set up authentication, both the protocol and passphrase must be specified.

User response

Retry the command, specifying both the **-authprotocol** and **-authpassphrase** parameters.

CMMVC9457E **The command failed because authentication must be setup if privacy is to be used.**

Explanation

This error can occur when an attempt is made to set up Simple Network Management Protocol (SNMP) privacy but authentication is not configured. Authentication must be configured before SNMP privacy can be set up.

User response

Use the **chsnmpserver -authprotocol protocol -authpassphrase passphrase** command to set up authentication, and then set up privacy.

CMMVC9458E **The command failed because both [-privprotocol] and [-privpassphrase] are required to set up snmp privacy.**

Explanation

This error can occur when an attempt is made to set up Simple Network Management Protocol (SNMP) privacy but the protocol or passphrase was not specified. To set up SNMP privacy, both a protocol and passphrase must be specified.

User response

Retry the command, specifying both the **-privprotocol** and **-privpassphrase** parameters.

CMMVC9459E **The command failed because the total drive count adds more than 12 drives.**

Explanation

This error can occur when an attempt is made to add more than 12 drives.

User response

Retry the command, specifying an integer for the - **totaldrivecount** parameter that is no greater than the current number of drives plus 12.

CMMVC9460E **The command failed because the total drive count is less or equal to the current drive count.**

Explanation

This error can occur when an attempt is made to reduce the number of drives or to add 0 drives. To expand an array, drives must be added.

User response

Retry the command, specifying an integer for the - **totaldrivecount** parameter that is greater than the current number of drives.

CMMVC9461E **The command failed because the total rebuild area count is less than the current rebuild area count.**

Explanation

This error can occur when an attempt is made to reduce the number of rebuild areas. Reducing the number of rebuild areas is not supported during array expansion.

User response

Retry the command, specifying an integer for the - **totalrebuildareas** parameter that is equal to or greater than the current number of rebuild areas.

CMMVC9463E **The command failed because the specified driveclass does not meet or exceed the goals of the array. Please select a driveclass with `lscompatibledriveclass`.**

Explanation

This error can occur when an attempt is made to add drives that are not from the same drive class or a superior drive class.

User response

Retry the command, specifying drives that are from the same drive class as the drives currently in the array, or a superior drive class. You can use the **svcinfolscompatibledriveclasses** command to display the drive classes that are compatible with a specified drive class.

CMMVC9471E **The command failed because remote users cannot specify a password.**

Explanation

This error occurs when an attempt is made to set a password for a remote user.

User response

Create a remote user but do not attempt to specify a password for the remote user.

CMMVC9473E **The command failed because the superuser password must be changed before the system can be configured.**

Explanation

This error occurs when an attempt is made to run an **svctask** command other than **chuser** or **chcurrentuser** when the superuser password is still set to the default value.

User response

Change the default password, and then retry the command. Passwords must contain more than 5 and fewer than 65 ASCII characters.

CMMVC9474E **The command failed because an insecure password was chosen.**

Explanation

This error can occur when an attempt is made to reset the password to the default password, or to use a password that does not comply with the password policy.

User response

Specify a password that complies with the password policy, and is not the default password.

CMMVC9475E **The node cannot be added because it does not support compressed volume copies in a standard storage pool.**

Explanation

This error occurs when an attempt is made to add a node that does not support real-time compression to an I/O group that includes volumes that use real-time compression. Certain node types support compressed volumes only in data reduction pools.

User response

Complete one of the following tasks:

- Retry the command, selecting an I/O group that does not include volumes that use real-time compression in standard storage pools.
- Decompress the compressed volumes in the I/O group, and then retry the command.
- Migrate the compressed volumes to a data reduction pool, and then retry the command.

CMMVC9510E **Enter at least one parameter.**

Explanation

This error occurs when no parameters are specified for a command that requires at least one parameter.

User response

Retry the command, specifying at least one parameter.

CMMVC9546E **The host port cannot be added as a host cannot have both iSCSI names and WWPNS.**

Explanation

This error occurs when an attempt is made to add an Internet Small Computer System Interface (iSCSI) or iSCSI Extensions for RDMA (iSER) port to a host that already has Fibre Channel or SAS ports, or to add Fibre Channel or SAS ports to a host that already has iSCSI or iSER ports. A host cannot be used for iSCSI or iSER protocols at the same time as Fibre Channel or SAS protocols.

User response

Use the **mkhost** command to create another host object, and then add the new host ports to the new host object.

Appendix A. Accessibility features for the system

Accessibility features help users who have a disability, such as restricted mobility or limited vision, to use information technology products successfully.

Accessibility features

These are the major accessibility features for the system:

- You can use screen-reader software and a digital speech synthesizer to hear what is displayed on the screen. HTML documents are tested by using JAWS version 15.0.
- This product uses standard Windows navigation keys.
- Interfaces are commonly used by screen readers.
- Keys are discernible by touch, but do not activate just by touching them.
- Industry-standard devices, ports, and connectors.
- You can attach alternative input and output devices.

The system online documentation and its related publications are accessibility-enabled. The accessibility features of the online documentation are described in [Viewing information in the information center](#).

Keyboard navigation

You can use keys or key combinations for operations and to initiate menu actions that can also be done through mouse actions. You can go to the system online documentation from the keyboard by using the keyboard shortcuts for your browser or screen-reader software. See your browser or screen-reader software Help for a list of keyboard shortcuts that it supports.

IBM and accessibility

See the [IBM Human Ability and Accessibility Center](#) for more information about the commitment that IBM has to accessibility.

Notices

This information was developed for products and services offered in the US. This material might be available from IBM in other languages. However, you may be required to own a copy of the product or product version in that language in order to access it.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

*IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
U.S.A.*

For license inquiries regarding double-byte character set (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

*Intellectual Property Licensing
Legal and Intellectual Property Law
IBM Japan, Ltd.
19-21, Nihonbashi-Hakozakicho, Chuo-ku
Tokyo 103-8510, Japan*

INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some jurisdictions do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM websites are provided for convenience only and do not in any manner serve as an endorsement of those websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you provide in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

*IBM Director of Licensing
IBM Corporation
North Castle Drive, MD-NC119
Armonk, NY 10504-1785*

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

The performance data discussed herein is presented as derived under specific operating conditions. Actual results may vary.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

Statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

All IBM prices shown are IBM's suggested retail prices, are current and are subject to change without notice. Dealer prices may vary.

This information is for planning purposes only. The information herein is subject to change before the products described become available.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

If you are viewing this information softcopy, the photographs and color illustrations may not appear.
